The dose of iodide of potassium is from two to ten grains or more, three times a day, given in dilute solution. Ricord rarely exceeded three scruples a day. Some practitioners have employed enormous doses, such as two, four, and even six drachms daily, without inconvenience. Dr. Buchanan, of Glasgow, assures us that he has given the pure salt in doses of half an ounce, without any precaution being observed by the patient, except to drink freely of diluents. Notwithstanding this testimony, Dr. Lawrie, of the same city, reports several cases of dryness and irritation of the throat, ending in severe spasmodic croup, and one case of death following the sudden occurrence of dyspnœa, caused by the use of this iodide, even when given in small doses. According to Dr. Gull, of London, the efficiency of the remedy is much increased by uniting it with carbonate of ammonia, in the proportion of two or three grains of the iodide to four or five of the carbonate.

Iodide of potassium passes quickly into the urine, in which it may be detected by first adding to the cold secretion a portion of starch, and then a few drops of nitric acid, when a blue colour will be produced. It has been detected in six minutes after having been swallowed. According to Schottin it passes slowly into the sweat. Taken in half-drachm doses daily, it did not appear in that secretion until five days had elapsed.

According to Ricord, this salt produces in some constitutions peculiar effects; such as eruptions of the skin, excessive diuresis, vascular injection of the conjunctiva and tumefaction of the eyelids, cerebral excitement like that produced by alcoholic drinks, and discharges from the urethra and vagina, resembling blennorrhœa. Eruptions of the skin were also observed by Dr. A. Van Buren, as a very common effect of large and long-continued doses of iodide of potassium, given to patients in the Bellevue Hospital, N. Y. Dr. John O'Rielly, of New York, reports several cases, in which, after the use of this iodide, spots like purpura were produced, invading first the face, and then the trunk and extremities. These became bullæ, sometimes an inch in diameter, filled with a purple liquid, and finally sphacelated spots ending in ulcers. Great constitutional disturbance coexisted, with swollen tongue, fetor, and salivation. The remedies found successful were nutritious diet, tonics, and stimulants. From the facts above mentioned, showing the power of iodide of potassium to render active mercury that is latent in the system, it is not improbable that the cases of Dr. O'Rielly were mercurial salivation, modified by a cachectic condition of the system, which caused the coincident eruption.

Iodide of potassium is employed as an external application in the form of ointment, either alone or mixed with iodine. (See *Unguentum Potassii Iodidi* and *Unguentum Iodinii Compositum.*)

S.;* Tinctura Iodi, *Br.;* Tinctura Iodinii Composita, *U. S.;* Unguentum Iodi, *Br.;* Unguent. Iodinii, *U. S.;* Unguent. Iodinii Compositum, *U. S.;* Unguent. Potassii Iodidi. B.

POTASSII SULPHURETUM. *U. S.* Potassa Sulphurata. *Br.* Hepar Sulphuris. *Dub.* *Sulphuret of Potassium. Sulphurated Potash. Liver of Sulphur.*

"Take of Sublimed Sulphur *a troyounce;* Carbonate of Potassa *two troyounces.* With the Sulphur rub the Carbonate, previously dried, and heat the mixture gradually in a covered crucible until it ceases to swell, and is completely melted. Then pour out the liquid on a marble slab, and when the mass is cold, break it into pieces, and keep these in a well-stopped bottle of green glass." *U. S.*

"Take of Carbonate of Potash, in powder, *ten ounces;* Sublimed Sulphur *five ounces.* Mix the Carbonate of Potash and the Sulphur in a warm mortar, and, having introduced them into a Cornish or Hessian crucible, let this be heated, first gradually, until effervescence has ceased, and finally to dull redness, so as to produce perfect fusion. Let the liquid contents of the crucible

be then poured out on a clean flagstone, and covered quickly with an inverted porcelain basin, so as to exclude the air as completely as possible while solidification is taking place. The solid product thus obtained should, when cold, be broken into fragments, and immediately enclosed in a green-glass bottle, furnished with an air-tight stopper." *Br.*

These processes are essentially the same, except that a greater heat is used in the Br. process, which somewhat modifies the result. When carbonate of potassa is melted with half its weight of sulphur, as in the U. S. process, the carbonic acid is expelled. The explanation heretofore given is as follows. Four eqs. of potassa and ten of sulphur may be supposed to react on each other. Three eqs of potassa are decomposed into three eqs. of potassium and three of oxygen. The three eqs. of potassium unite with nine eqs. of sulphur to form three eqs. of tersulphuret of potassium. The three eqs. of oxygen, by uniting with the remaining eq. of sulphur, form one eq. of sulphuric acid, which combines with the undecomposed eq. of potassa to form sulphate of potassa. Thus, the preparation may be considered to be a mixture of tersulphuret of potassium with sulphate of potassa; and the French Codex sulphuret, made from the same proportion of carbonate and sulphur, is stated in that work to have the same composition. The fact is, however, that the composition varies with the heat employed. If the heat do not exceed 365° F., the resulting preparation will contain hyposulphite of potassa; if above 572° F., sulphate of potassa. (*Fordos and Gélis.*) The U. S. preparation, therefore, which is made at the temperature of fusion, probably contains hyposulphite of potassa, and may be represented by the formula $2KS_3+KO,S_2O_2$; three eqs. of CO_2 escaping: while the British, being prepared at a red heat, contains sulphate of potassa, with the formula $3KS_3+KO,SO_3$; four eqs. of CO_2 escaping.

The Pharmacopœias use the carbonate of potassa from pearlash; but in the process of M. Henry, which is stated to be the best yet devised, the pure carbonate of potassa is employed. His formula is as follows. Mix two parts of real salt of tartar with one of roll sulphur reduced to powder, and put the mixture into flat-bottomed matrasses, which should be only two-thirds filled. These are placed on a sand-bath, and the fire is applied so as, at first, to produce only a gentle heat, which is afterwards increased. Care must be taken that the necks of the matrasses do not become obstructed. The heat is continued, until the matter is brought to the state of tranquil fusion, when it is allowed to cool. The mass obtained, which is compact, smooth, and of a fine yellow colour, is broken into pieces, and preserved in well-stopped bottles.

Properties, &c. Sulphuret of potassium, when properly prepared, is a hard, brittle substance, having a nauseous, alkaline, and bitter taste. Its colour is liver-brown, and hence its name of *hepar sulphuris* or *liver of sulphur*. The colour of the surface of a fresh fracture is brownish-yellow. It is inodorous when dry, but emits a slightly fetid smell when moist, owing to the extrication of a little sulphuretted hydrogen gas. It is soluble in water, forming an orange-yellow liquid, and exhaling the smell of sulphuretted hydrogen. By exposure to the air it attracts oxygen, and the sulphuret of potassium is gradually changed into sulphate of potassa, when the preparation becomes inodorous, and white on the surface. The solution is decomposed by the mineral acids, which extricate sulphuretted hydrogen, and precipitate the excess of sulphur. It is also incompatible with solutions of most of the metals, which are precipitated as sulphurets. When boiled with an excess of muriatic acid and filtered, it gives a yellow precipitate with bichloride of platinum, and a white one with chloride of barium. The preparation of the Br. Pharmacopœia yields about three-fourths of its weight to alcohol; the portion dissolved being sulphuret of potassium, and the undissolved portion sulphate of potassa. B.

Medical Properties and Uses. Sulphuret of potassium is a local irritant, and, in small and repeated doses, is said to increase the frequency of the pulse, heat of the skin, and different secretions, especially the mucous. Occasionally it vomits and purges. It acts, moreover, as an antacid, and produces the alterative effects

of sulphur. By some it is maintained to be sedative, and directly to reduce the action of the heart. It probably does so, when taken in considerable quantities, by the development of sulphuretted hydrogen. In overdoses it acts, according to Orfila, as a violent poison, corroding the stomach, and depressing the powers of the nervous system. Acetate of lead or acetate of zinc may be used as an antidote; but the latter is preferable, as less likely to act injuriously in an overdose, and having besides emetic properties. The complaints in which it has been most advantageously employed are chronic rheumatism and gout, and various cutaneous affections. It has been given also in painters' colic, asthma, and chronic catarrh, and acquired a short-lived reputation as a remedy in croup, after the publication of the essay to which the prize offered by Napoleon for the best dissertation on that disease was awarded. It is said, in some cases of cancer, to have assisted the palliative operation of hemlock. In consequence of forming insoluble sulphurets with the metallic salts, it has been proposed as an antidote for some mineral poisons; but Orfila has shown that it does not prevent their effects. Dissolved in water, it has proved efficacious as an external application in cutaneous diseases, and in scabies is an almost certain remedy. It may be used for this purpose in the form of lotion, bath, or ointment. For a lotion it may be dissolved in water in the proportion of from fifteen to thirty grains to the fluidounce, and for a bath the same quantity or rather more may be added to a gallon of water. A very small proportion of muriatic or sulphuric acid may in either case be added to the solution. The ointment is made by mixing half a drachm of the sulphuret with an ounce of lard. The odour is very favourably modified, whether in solution or the state of ointment, by incorporating with it a little oil of anise. (See *Anisum*. p. 127.) The dose of sulphuret of potassium is from two to ten grains, repeated several times a day, and given in pill with liquorice, or in solution with syrup. In infantile cases of croup, from one to four grains were given every three or four hours.

PULVERES.

Powders.

The form of powder is convenient for the exhibition of substances which are not given in very large doses, are not very disagreeable to the taste, have no corrosive property, and do not deliquesce rapidly on exposure. As the effect of pulverization is to expose a more extended surface to the action of the air, care should be taken to keep substances which are liable to be injured by such exposure in closely-stopped bottles. In many instances it is also important to exclude the light, which exercises a deleterious influence over numerous medicines when minutely divided. This may be done by coating the bottles with black varnish. In relation to substances most liable to injury from these causes, the best plan is to powder them in small quantities as wanted for use.*

* In contradiction to what has been stated in the text in relation to keeping powders in well-stopped bottles, it is asserted by M. Hérouard, a French pharmaceutist, that this plan, instead of preserving powders, tends in fact to their more speedy and certain change. Whatever pains may be taken in drying medicines previously to powdering them, most of them during the process attract moisture, so as to put themselves in this respect in equilibrium with the surrounding air; and, if enclosed in this state in air-tight vessels, they are exposed to injurious influence from their own absorbed water, which, vaporized in hot weather, is in the colder seasons condensed on the inner surface of the vessel, and determines a movement of fermentation; and even cryptogamic growths appear. The best method of preservation, the author thinks, is to enclose the powders in strong paper bags of a blue or gray colour, so as to exclude the light, while the air has exit or entrance through the porous walls. Whatever may be our theoretical opinions on the point, M Hérouard asserts the fact, as the result of observation, that powders keep best in this way. They may be more likely to cake or harden into aggregate masses; but this disadvantage is easily counteracted by a new pulverization when required. (*Journ. de Pharm.*, Août, 1862, p. 98.) There is probably some truth in these statements; and the inference may at least be drawn, that, where powders are kept in air-tight bottles, they should be thoroughly dried, after pulverization, before being enclosed. (*Note to the twelfth edition.*)

Powders may be divided into the *simple*, consisting of a single substance, and the *compound*, of two or more mixed together. The latter only are embraced under the present head. In the preparation of the compound powders, the ingredients, if of different degrees of cohesion or solidity, should be pulverized separately and then mixed. An exception, however, is when one substance is employed to facilitate by its hardness the minute division of another, as in the *compound powder of ipecacuanha*. Deliquescent substances, and those containing fixed oil in large proportion, should not enter into the composition of powders intended to be kept; the former because they render the preparation damp and liable to spoil; the latter, because they are apt to become rancid, and impart an unpleasant odour and taste. When deliquescent substances are extemporaneously prescribed, the apothecary should enclose them before delivery in tin foil or other impervious covering; and the same remark is applicable to volatile powders, as carbonate of ammonia and camphor.

The lighter powders may in general be administered in water or other thin liquid; the heavier, such as those of metallic substances, require a more consistent vehicle, as syrup, molasses, honey, or one of the confections. Resinous powders, if given in water, require the intervention of mucilage or sugar.

In the act of powdering, the whole substance in the mortar should not be beaten till completely pulverized; as the portion already powdered interferes with the action of the pestle upon the remainder, while the finer matter is apt to be dissipated; so that there is a loss both of time and material. The proper plan is to sift off the fine powder after a short continuance of the process, then to return the coarser parts to the mortar, and to repeat several times this alternate pulverization and sifting, until the process is completed. Care should be taken to mix thoroughly the several portions of fine powder thus obtained.* (See *pages* 913 and 914.)

The preparations of this class, which have been dismissed at the recent revision of the Pharmacopœias, are the *Compound Powder of Aloes*, Lond.; the *Compound Powder of Alum*, Ed.; and the *Citrated Effervescing Powders*, Ed. W.

* *Granulated Powders.* A new method of preparing powders for use has lately been introduced, consisting in converting them into minute granules, such as those of which salt of tartar consists, and of which there have long been a few examples, in which the object was to obviate change from atmospheric influence by diminishing the surface of exposure. In the new *granulated powders*, not only is the advantage arising from mere aggregation of particles gained, but the granules are further protected against change by receiving a distinct coating, which, being generally saccharine, has the additional advantage that it covers the taste of the powders, and much facilitates their administration. Placed on the tongue in quantities, less or more, they may be swallowed without difficulty, by simply washing them down with a little water; or they may be stirred up with water in a wineglass, and then swallowed.

Dr. Thos. Skinner, in a paper contained in the *Pharmaceutical Journal* (May, 1862, p. 572), gives the following plan of preparing these granulated powders, suggested by Mr. S. Banner, of Liverpool. The powder to be granulated should be freshly prepared. In general it is not at all necessary that it should be so fine as to be impalpable. The powder is first mixed in a mortar with enough mucilage of gum arabic to make a mass that will easily crumble; or it may be made into a plastic mass, which is to be rolled into thin cakes, and dried. The material is then to be broken up in a mortar, and sifted. For this purpose three sieves are required, with 12, 16, and 20 meshes, respectively, to the inch; which are to be fitted together, one over the other, the coarsest at top and the finest at bottom. The broken up mass is put in the upper sieve, and rubbed through by the open hand; the conjoined sieves are then shaken as in sifting; and, this part of the process being completed, they are separated. The larger granules are found in the middle sieve, the smaller in the lowermost, and the waste powder on a leather or parchment drum beneath. This waste is to be worked over again. The two sizes of granules are kept apart. If not already dry, as they always are when the material is first made into cakes, they are to be carefully dried; and are next put into a mortar, and, a strong tincture of tolu (℥ij to f℥i), aromatized if desired, having been added, are stirred constantly till their surface appears glossy; after which they are again dried, and thus prepared for use. The proportion of gum used is about one-sixteenth of the weight of the granules, that of tolu balsam too small to be worth estimating.

In France the granular powders are usually made with the addition of sugar, which if in fixed proportion, as one to one, or one to two, can be of no inconvenience in relation to the estimation of the dose. (*Note to the twelfth edition.*)

PULVERES EFFERVESCENTES. *U. S.* *Effervescing Powders. Soda Powders.*

"Take of Bicarbonate of Soda, in fine powder, *three hundred and sixty grains;* Tartaric Acid, in fine powder, *three hundred grains.* Divide each of the powders into twelve equal parts, and keep the parts, severally, of the Bicarbonate and of the Acid in separate papers of different colours." *U. S.*

This is a formula, introduced into the present edition of our national Pharmacopœia, for a preparation which has been long in use under the name of *soda powders.* The powders consist, severally, of twenty-five grains of the acid in one paper, and thirty of the bicarbonate in the other. They are administered in solution. An acid and an alkaline powder may be dissolved in separate portions of water and then mixed; or they may be thrown together, or successively into the same portion of water. The whole draught should be half a pint or somewhat less. It may be rendered more agreeable by adding two or three fluidrachms of syrup of ginger or orange peel to the water, before dissolving the powders. The rationale is simple. The tartaric acid seizes the alkali of the bicarbonate, forming a tartrate of soda, while the carbonic acid escapes with effervescence. The effervescing powders are refrigerant and slightly laxative; and afford an agreeable and refreshing drink, suitable to febrile complaints, and generally very acceptable to the stomach. W.

PULVERES EFFERVESCENTES APERIENTES. *U. S.* *Aperient Effervescing Powders. Seidlitz Powders.*

"Take of Bicarbonate of Soda, in fine powder, *a troyounce;* Tartrate of Potassa and Soda, in fine powder, *three troyounces;* Tartaric Acid, in fine powder, *four hundred and twenty grains.* Mix intimately the Bicarbonate of Soda with the Tartrate of Potassa and Soda, and divide this mixture into twelve equal parts. Then divide the Tartaric Acid into the same number of equal parts. Lastly, keep the parts, severally, of the mixture and of the Acid in separate papers of different colours." *U. S.*

These powders, so long and so usefully employed under the name of *Seidlitz powders*, have for the first time found a place among officinal preparations in the present edition of the U. S. Pharmacopœia. Though named from the saline springs of Seidlitz, in Bohemia, they do not correspond in composition with those famous waters. Of each pair of powders, one, much the smaller of the two, contains thirty-five grains of tartaric acid, the other forty grains of bicarbonate of soda mixed with two drachms of Rochelle salt. The acid powder is usually put into a white, the alkaline into a blue paper; and a number of them are enclosed in a paper or tin box. They should not be kept in a damp place, as the tartaric acid is liable to be dissolved by the moisture, and absorbed into the substance of the paper; thus altering the due proportion of the ingredients. We have known the whole of the contents of the white paper thus to disappear in the course of two or three years. In such a case, however, the paper itself may be torn up and put into the water, to which it soon imparts the acid. The Rochelle salt is the ingredient upon which the aperient property mainly depends. In their administration, each powder is dissolved separately, the smaller in a fluidounce or more of water, the larger in twice or three times the quantity; and the two solutions are mixed gradually. A reaction takes place between the tartaric acid and the bicarbonate of soda, by which tartrate of soda is produced, adding somewhat to the laxative property of the draught, and carbonic acid escapes, causing a brisk effervescence. The acid is in slight excess, and thus causes an agreeable acidity in the solution. These powders are refrigerant and aperient, and generally very acceptable to the stomach in consequence of the carbonic acid eliminated. They are especially adapted to febrile cases with a somewhat irritable stomach. One pair of them will generally operate slightly; but, if required, two may be given at once; or the dose may be repeated every three or four hours till the desired effect is produced. The flavour may sometimes be advantageously improved by adding syrup of ginger, orange peel, or lemon to one of the solutions before admixture. W.

PULVIS ALOËS ET CANELLÆ. *U.S.* *Powder of Aloes and Canella. Hiera Picra.*

"Take of Socotrine Aloes, in fine powder, *twelve troyounces;* Canella, in fine powder, *three troyounces.* Rub them together until they are thoroughly mixed." *U. S.*

This preparation has long been known under the name of *hiera picra.* The canella serves to correct the griping property, and imperfectly to cover the taste of the aloes; but the bitterness of the latter is still very obvious in the mixture, which would be better given in the form of pill. It is a popular remedy in amenorrhœa, and may be used for all the purposes to which aloes is applied. It is sometimes administered in domestic practice, infused in wine or spirit. The dose is from ten to twenty grains. W.

PULVIS AMYGDALÆ COMPOSITUS. *Br.* CONFECTIO AMYGDALÆ. *Lond.* CONSERVA AMYGDALARUM. *Ed.* *Compound Powder of Almonds.*

"Take of Sweet Almonds *eight ounces;* Refined Sugar, in powder, *four ounces;* Gum Arabic, in powder, *one ounce.* Steep the Almonds in warm water until their skins can be easily removed; and, when blanched, dry them thoroughly with a soft cloth, and rub them lightly in a mortar to a smooth consistence. Mix the Gum and the Sugar; and, adding them to the pulp gradually, rub the whole to a coarse powder. Keep it in a lightly covered jar." *Br.*

This is nothing more than the old *Almond Confection* under a new name. It is intended to afford a speedy method of preparing the almond mixture, which, when made immediately from the almonds, requires much time, and which cannot be kept ready made in the shops. But, from its liability to be injured by keeping, it was omitted from our Pharmacopœia, which directs the almond mixture to be made immediately from the ingredients.

Off. Prep. Mistura Amygdalæ, *Br.* W.

PULVIS ANTIMONIALIS. *Br.* *Antimonial Powder.*

"Take of Oxide of Antimony *one ounce;* Precipitated Phosphate of Lime *two ounces.* Mix them thoroughly." *Br.*

This preparation has been introduced into the British Pharmacopœia as a substitute for the different forms of antimonial powder formerly officinal with the British Colleges. In order that the subject may be properly understood, it will be necessary to introduce a notice of the powder as formerly directed to be prepared by the London and Dublin Colleges; the process of the Edinburgh College having been so similar to the London, that it does not require special consideration.

Antimonial Powder of the London College. The following was the London process. "Take of Tersulphate of Antimony, powdered, *a pound;* Horn Shavings *two pounds.* Mix, and throw them into a red-hot crucible, and stir constantly until vapour ceases to arise. Rub the residue to powder, and put it into a crucible. Then apply heat, and raise it gradually to redness, and keep it so for two hours. Rub the remaining powder until it is as fine as possible." *Lond.*

This preparation consists mainly of bone-phosphate of lime, or calcined bone, mixed with antimonious acid, and is intended to furnish a substitute for the celebrated nostrum of Dr. James, an English physician who died in 1776, and after whom the original preparation was called *James's powder.* Dr. Pearson, of London, found the genuine powder, on analysis, to consist of phosphate of lime and oxidized antimony, and, guided by his results, devised the formula adopted by the London College. By burning the materials directed by the College, the sulphur is expelled in the form of sulphurous acid, and the antimony oxidized; while the horn, which is of the nature of bone, has its animal matter converted into charcoal. By the subsequent calcination the charcoal is dissipated, leaving only the phosphate of lime of the horn mixed with the oxidized antimony.

The antimonial powder made by this formula is a tasteless, inodorous, gritty powder, of a dull-white colour. As often prepared it is insoluble in water; but

usually a small portion, consisting of antimonite and superphosphate of lime, dissolves in boiling distilled water. Its composition varies exceedingly, a circumstance which forms a strong objection to it as a medicine. When entirely insoluble in boiling water, it probably contains nothing but antimonious acid and phosphate of lime; for, when its soluble constituents are absent, the teroxide is absent also. The best samples consist of "a mixture chiefly of antimonious acid and phosphate of lime, with some sesquioxide [teroxide] of antimony, and a little antimonite of lime." (*Ed.*) To these ingredients may be added superphosphate of lime, which was found in small quantity by Dr. D. Maclagan, of Edinburgh. This writer obtained in his experiments about 50 per cent. of antimonious acid, 45 of phosphate of lime, nearly 4 of teroxide, and not quite one of antimonite and superphosphate of lime. The antimonial powder, sold by the representatives of Dr. James, is more active, and more uniform in its effects, than the imitation powder of the Pharmacopœias; its greater activity being explained by the presence of a greater proportion of teroxide, which Dr. Maclagan found to vary from 4 to 10 per cent. In analyzing the London antimonial powder, the first step is to act on it with boiling distilled water. If any antimonite should be dissolved, the solution will form with sulphuretted hydrogen an orange-coloured precipitate of quadrisulphuret of antimony; if superphosphate be present, nitrate of silver will throw down phosphate of silver. What remains of the powder, unacted on by the distilled water, is next digested with muriatic acid, which dissolves the phosphate of lime, and also teroxide of antimony if present, and leaves a residue which is the antimonious acid. If teroxide be present in the muriatic solution, it will be precipitated by sulphuretted hydrogen, as an orange-coloured tersulphuret, and from the filtered solution, water of ammonia will throw down the phosphate of lime. In this way all the ingredients of antimonial powder may be detected and separated. It might be supposed that the muriatic solution would be more readily tested for teroxide by means of water, which causes a white precipitate of oxychloride in this solution; but there seems to be some ambiguity in relation to the action of water. The Edinburgh College, in its formula of tests, stated that the muriatic solution of the residue, left after the exhaustion by water, does not become turbid by dilution; but, according to Dr. Barker and Dr. Pereira, this effect sometimes takes place. These different results may be explained by the different qualities of the preparation. A small quantity of teroxide may be in the muriatic solution, and yet not be precipitated by water as oxychloride; while a larger quantity will be so precipitated. On the other hand, a precipitate may be produced with water, without proving the presence of teroxide; for, unless the antimonial powder be most carefully exhausted by the distilled water before being subjected to the acid, the muriatic solution may contain antimonite of lime, which, like the teroxide, gives it the property of becoming turbid with water.

The Dublin Antimonial Powder. Influenced, apparently, by considerations such as above presented, the Dublin College contrived the following process, with the object of having a preparation of definite constitution, and of an activity to be relied on. "Take of Tartarized Antimony, Phosphate of Soda, each, *four ounces* [avoirdupois]; Chloride of Calcium *two ounces* [avoird.]; Solution of Ammonia *four fluidounces* [Imperial measure]; Distilled Water *one gallon and a half* [Imp meas.], or *a sufficient quantity*. Dissolve the Tartarized Antimony in half a gallon, and the Phosphate of Soda and Chloride of Calcium, each, in a quart of the Water. Mix the solutions of the Tartarized Antimony and Phosphate of Soda when cold, and then pour in the solution of Chloride of Calcium, having first added to the latter the Water of Ammonia. Boil now for twenty minutes, and, having collected the precipitate, which will have then formed, on a calico filter, wash it with hot distilled water until the liquid which passes through ceases to give a precipitate with a dilute solution of nitrate of silver. Finally, dry the product by a steam or water heat, and reduce it to a fine powder." *Dub.*

This formula was a new one of the Dublin Pharmacopœia of 1850, and was an improvement on the process of Mr. Chenevix, proposed in 1801, for obtaining

antimonial powder in the humid way. By this formula the liquid, resulting from mixing aqueous solutions of tartar emetic and phosphate of soda, is precipitated by a solution of chloride of calcium, previously mixed with water of ammonia. The water of ammonia throws down teroxide of antimony from the tartar emetic; and the chloride of calcium, phosphate of lime from the phosphate of soda; and the mixed precipitate, washed, dried, and reduced to fine powder, constitutes what was the Dublin antimonial powder. It is quite a different preparation from that previously described; inasmuch as all the antimony present is in a state of teroxide. It should not have been called antimonial powder, but designated by a distinct name. The process by which it is obtained is certainly a great improvement on that usually followed. It is doubtful whether the phosphate of lime adds anything to its efficacy; and, if not, the preparation is equivalent to teroxide of antimony, used in a smaller dose.

British Antimonial Powder. The formula for this is the one given at the head of the present article. It is the preparation now officinal in Great Britain to the exclusion of the others. The only essential difference between it and the Dublin powder is that its ingredients are taken already prepared and mixed in fixed proportion, while those of the latter result simultaneously from one operation. It is of course much more easily prepared, and less liable to uncertainty from any error in the process.

Medical Properties and Uses. This preparation is stated to be alterative, diaphoretic, purgative, or emetic, according to the dose in which it is given. Until within a few years it was often prescribed in febrile diseases, with a view to its diaphoretic effect. According to Dr. A. T. Thomson, it is advantageously given in acute rheumatism, conjoined with camphor, calomel, and opium, and with calomel and guaiac in several cutaneous affections. The estimation in which this preparation is held is very various. The late Dr. Duncan, referring to the preparation of the Lond. and Ed. Colleges, characterized it as one of the best antimonials we possess; yet he acknowledged that its effects are very unequal, either from idiosyncrasy in the patient, or variations in its composition. Dr. Thomson found it sometimes to answer his expectations, but as often to disappoint them. Mr. Brande admits its activity sometimes, and entire inertness at others, which he attributes to the presence or absence of *teroxide* of antimony. Of course these observations had reference to the former antimonial powder of the British Colleges; and it was this uncertainty of its action that led to its omission from the U. S. Pharmacopœia, upon the revision of 1830.

The antimonial powder at present officinal in Great Britain is exempt from the objection of irregularity of composition. Nevertheless, as it depends for its greater or less energy on the presence or absence in the alimentary canal of an acid which may form a salt with the antimonial oxide, it cannot always be relied on for a definite effect, being sometimes mild, and sometimes more active than might be desirable. The dose, as a diaphoretic, is from three to eight grains every third or fourth hour, given in the form of pill. In larger doses it is purgative and emetic. It is impossible to give precise directions as to the dose of the former London powder; as it sometimes proved violently emetic in moderate doses, and at other times produced no obvious effect even in doses of one hundred grains.

The late *Dublin* antimonial powder, which may be considered as essentially identical with the British, was tried therapeutically in twenty cases of disease, chiefly rheumatism, pneumonia, and bronchitis, by Dr. Jonathan Osborne, of Dublin. In five-grain doses, given evening and night, it produced, variously, nausea, vomiting, and perspiration. In half the cases it acted gently on the bowels. The teroxide, given separately in three-grain doses, evening and night, produced similar effects. (*Pharm. Journ.*, Jan. 1855, p. 331.) Practitioners who may wish to prescribe the antimonial powder, in its present more certain form, should add (*Br.*) or (*Dub.*) to its name; so as to be secured against the old *Lond* and *Ed.* preparation. B.

PULVIS AROMATICUS. *U. S.*, *Ed.* PULVIS CINNAMOMI COMPOSITUS, *Br.* *Aromatic Powder. Compound Powder of Cinnamon.*

"Take of Cinnamon, in fine powder, Ginger, in fine powder, each, *two troyounces;* Cardamom, deprived of the capsules and in fine powder, Nutmeg, in fine powder, each, *a troyounce.* Rub them together until they are thoroughly mixed." *U. S.*

"Take of Cinnamon Bark, in powder, Cardamom Seeds, in powder, Ginger, in powder, of each, *one ounce.* Mix them thoroughly, pass the powder through a fine sieve, and finally rub it lightly in a mortar. Keep it in a stoppered bottle." *Br.*

These powders now closely resemble each other; the only material difference being that, instead of the cardamom and nutmeg of the U. S. Pharmacopœia, together equal in quantity to each of the other ingredients, the British takes only the cardamom in double the proportion, or equal to each of the others. The present British formula differs from that of 1864, in the substitution of ginger for nutmeg, cloves, and saffron, and especially in the absence of sugar, which in the latter constituted two-thirds of the whole, having probably been added in order that, by the addition of a little water to the powder, an aromatic confection might be readily prepared, without the necessity of keeping it. It is obvious that this end may be as effectually attained by the addition of a little syrup to the present powder.

The cardamom seeds should always be separated from their capsules before being weighed; and the powder, when prepared, should be kept in well-stopped bottles. The aromatic powder is stimulant and carminative, and the U. S. preparation may be given in the dose of from ten to thirty grains, in cases of enfeebled digestion with flatulence; but it is chiefly used as a corrigent and adjuvant of other medicines. A mixture of aromatic powders in the form of a cataplasm is much used as a mild rubefacient, especially in nausea and vomiting, being applied over the epigastrium. Such mixtures are commonly called *spiced plasters.* The following is a good formula. Take of ginger, cloves, cinnamon, and black pepper, each, in powder, an ounce; tincture of ginger half a fluidounce; honey a sufficient quantity. Mix the powders, and then add the tincture and honey, so as to form a stiff cataplasm.*

Off. Prep. Confectio Aromatica, *U. S.;* Confectio Opii, *U. S.;* Pilula Aloes et Ferri, *Br.;* Pilula Cambogiæ Composita, *Br.* W.

PULVIS CATECHU COMPOSITUS. *Br.* *Compound Powder of Catechu.*

"Take of Catechu, in powder, *four ounces;* Kino, in powder, Rhatany Root, in powder, of each, *two ounces;* Cinnamon Bark, in powder, Nutmeg, in powder, of each, *one ounce.* Mix them thoroughly, pass the powder through a fine sieve, and finally rub it lightly in a mortar. Keep it in a stoppered bottle." *Br.*

This is an agreeable form for the administration of kino or catechu; but we do not see the propriety of mixing two substances so similar in their properties, at least in relation to taste and medicinal effect, that they may be considered identical. The dose is from fifteen to thirty grains. W.

PULVIS CRETÆ AROMATICUS. *Br.* CONFECTIO AROMATICA. *Lond.* *Aromatic Powder of Chalk.*

"Take of Cinnamon Bark, in powder, *four ounces;* Nutmeg, in powder, Saffron, in powder, of each, *three ounces;* Cloves, in powder, *one ounce and a*

* *Aromatic Sugar.* Mr. Wm L. Turner proposes an ingenious mode of obtaining the effects of the aromatic powder, in certain cases where the use of the powder itself would be inconvenient. He prepares an aromatic sugar by submitting eight ounces of the freshly prepared powder to percolation with stronger alcohol to exhaustion, pouring the percolate over eight ounces of sugar, and evaporating at a low heat. The sugar thus prepared may be added to mixtures, solutions, &c., requiring aromatic addition. (*Am. Journ. of Pharm.*, March, 1869, p. 118.)—*Note to the thirteenth edition.*

half; Cardamom Seeds, in powder, *one ounce;* Refined Sugar, in powder, *twenty-five ounces;* Prepared Chalk *eleven ounces.* Mix them thoroughly, pass the powder through a fine sieve, and finally rub it lightly in a mortar. Keep it in a stoppered bottle." *Br.*

This is the former "Aromatic Powder" of the Br. Pharmacopœia, with the addition of chalk, and differs from the former "Aromatic Powder of Chalk" only in having the ingredients severally directed instead of being mixed in the form of the "Aromatic Powder." It is a warm stimulant and astringent, as well as antacid; and is well calculated for diarrhœa connected with acidity, and without inflammation. In such a combination, however, the due proportion, and even the choice of the ingredients, vary so much with the symptoms, that they might with propriety be left to extemporaneous prescription. The dose is from thirty to sixty grains, given in mucilage or sweetened water, and frequently repeated.

Off. Prep. Pulvis Cretæ Aromaticus cum Opio, *Br.* W.

PULVIS CRETÆ AROMATICUS CUM OPIO. *Br. Aromatic Powder of Chalk and Opium.*

"Take of Aromatic Powder of Chalk *nine ounces and three-quarters;* Opium, in powder, *a quarter of an ounce.* Mix them thoroughly, pass the powder through a fine sieve, and finally rub it lightly in a mortar. Keep it in a stoppered bottle." *Br.*

The addition of the opium greatly increases the efficacy of the compound powder of chalk in diarrhœa; and its equal diffusion through the powder presents this advantage, that it may be conveniently given in minute doses applicable to infantile cases. Two scruples of the powder contain a grain of opium. In the diarrhœa of adults from ten to twenty grains may be given for a dose, and repeated several times a day, or after each evacuation. W.

PULVIS IPECACUANHÆ COMPOSITUS. *U.S., Br.* PULVIS IPECACUANHÆ CUM OPIO. *Br.* 1864. PULVIS IPECACUANHÆ ET OPII. *U.S.* 1850. *Compound Powder of Ipecacuanha. Powder of Ipecacuanha and Opium. Dover's Powder.*

"Take of Ipecacuanha, in fine powder, Opium, dried and in fine powder, each, *sixty grains;* Sulphate of Potassa *a troyounce.* Rub them together into a very fine powder." *U.S.*

The British Pharmacopœia directs the same ingredients in the same proportions, though in a larger quantity, and orders them to be well rubbed together, the powder to be passed through a fine sieve, rubbed lightly in a mortar, and kept in a stoppered bottle.

It is a subject for congratulation that, at last, the name of this important compound is identical in the two Pharmacopœias.

The sulphate of potassa in this preparation serves, by the hardness of its particles, to promote that minute division and consequent thorough intermixture of the opium and ipecacuanha upon which the peculiar virtues of the compound depend. It also serves to dilute the active ingredients, and thus allow of their division into minute doses adapted to the complaints of children. This composition, though called Dover's powder, does not precisely correspond with that originally recommended by Dr. Dover, which was prepared as follows. Four ounces of nitrate of potassa and the same quantity of sulphate of potassa were mixed in a red-hot crucible, and afterwards very finely powdered; one ounce of opium, sliced, was then added, and ground to powder with the saline mixture; lastly, an ounce of ipecacuanha and an ounce of liquorice root, in powder, were mixed with the other ingredients. This process was adopted in a former French Codex, and has been retained with little change in the present.

This powder is an admirable anodyne diaphoretic, not surpassed, perhaps, by any other combination in the power of promoting perspiration. Opium itself has a strong tendency to the skin, evinced both by the occasional diaphoresis,

and by the itching and tingling sensation which it excites. While the vessels of the skin are stimulated by this ingredient, the secreting pores are relaxed by the ipecacuanha, and the combined effect is much greater than that which results from either separately. At the same time, the general stimulating influence of the opium, and its tendency to operate injuriously on the brain, are counteracted so that the mixture may be given with safety in cases which might not admit of the use of opium alone. The preparation is applicable to all cases, not attended with much fever, cerebral disease, or sick stomach, in which there is an indication for profuse diaphoresis, especially in painful affections, or those connected with unhealthy discharges. It is admirably adapted to the phlegmasiæ, particularly rheumatism and pneumonia, when complicated with a typhoid tendency, or after sufficient depletion. Under similar circumstances, it is useful in dysentery, diarrhœa, and the various hemorrhages, especially that from the uterus. It is sometimes also given in dropsy. In bowel affections, and whenever the hepatic secretion is deranged, it is frequently combined with small doses of calomel.

Ten grains of the powder contain one grain of opium. The dose is from five to fifteen grains, given diffused in water, or mixed with syrup, or in the form of bolus, and repeated at intervals of four, six, or eight hours, when it is desirable to maintain a continued diaphoresis. Its action may be promoted by warm drinks, such as lemonade or balm tea, which, however, should not be given immediately after the powder, as they might provoke vomiting. W.

PULVIS JALAPÆ COMPOSITUS. *U. S.*, *Br.* *Compound Powder of Jalap.*

"Take of Jalap, in fine powder, *a troyounce;* Bitartrate of Potassa, in fine powder, *two troyounces.* Rub them together until they are thoroughly mixed." *U. S.*

"Take of Jalap, in powder, *five ounces;* Acid Tartrate of Potash *nine ounces;* Ginger, in powder, *one ounce.* Mix them thoroughly, pass the powder through a fine sieve, and finally rub it lightly in a mortar." *Br.*

The bitartrate, by being rubbed with the jalap, is thought to favour its more minute division, while it increases its hydragogue effect. A combination of these two ingredients, though with a larger proportion of cream of tartar (see *Jalapa*), forms a good cathartic in dropsy, and scrofulous diseases of the joints and glands. The dose of the powder is from thirty grains to a drachm. W.

PULVIS KINO COMPOSITUS. *Br.*, *Lond.* Pulvis Kino cum Opio. *Br.* 1864. *Compound Powder of Kino. Powder of Kino and Opium.*

"Take of Kino, in powder, *three ounces and three-quarters;* Opium, in powder, *a quarter of an ounce;* Cinnamon Bark, in powder, *one ounce.* Mix them thoroughly, pass the Powder through a fine sieve, and finally rub it lightly in a mortar. Keep it in a stoppered bottle." *Br.*

This is an anodyne astringent powder, useful in some forms of diarrhœa, but of which the composition would be better left to extemporaneous prescription; as the proportion of the ingredients should vary with the circumstances of the case. Twenty grains contain one grain of opium. The dose is from five grains to a scruple. W.

PULVIS OPII COMPOSITUS. *Br.* *Compound Powder of Opium.*

"Take of Opium, in powder, *one ounce and a half;* Black Pepper, in powder, *two ounces;* Ginger, in powder, *five ounces;* Caraway Fruit, in powder, *six ounces;* Tragacanth, in powder, *half an ounce.* Mix them thoroughly, pass the powder through a fine sieve, and finally rub it lightly in a mortar. Keep it in a stoppered bottle." *Br.*

This seems to have been introduced in order to have at hand all the dry ingredients of the Confection of Opium. (See *Confectio Opii*, p. 1090.)

Ten grains of the powder contain one grain of opium.

Off. Prep. Confectio Opii, *Br.* W.

PULVIS RHEI COMPOSITUS. *U.S., Br. Compound Powder of Rhubarb.*

"Take of Rhubarb, in fine powder, *four troyounces;* Magnesia *twelve troyounces;* Ginger, in fine powder, *two troyounces.* Rub them together until they are thoroughly mixed." *U. S.*

"Take of Rhubarb Root, in powder, *two ounces;* Light Magnesia, *six ounces;* Ginger, in powder, *one ounce.* Mix them thoroughly, and pass the powder through a fine sieve." *Br.*

This is a good laxative antacid, well adapted to bowel complaints, especially in children. The dose for an adult is from half a drachm to a drachm; for a child two or three years old, from five to ten grains. W.

PULVIS SCAMMONII COMPOSITUS. *Br. Compound Powder of Scammony.*

"Take of Scammony, in powder, *four ounces;* Jalap, in powder, *three ounces;* Ginger, in powder, *one ounce.* Mix them thoroughly, pass the powder through a fine sieve, and finally rub it lightly in a mortar." *Br.*

This does not appear to us a very eligible preparation. Though the ginger may tend to correct the griping property of the purgative ingredients, the jalap too closely resembles the scammony in its operation to exert any important modifying influence upon it. The dose is from ten to twenty grains. W.

PULVIS TRAGACANTHÆ COMPOSITUS. *Br. Compound Powder of Tragacanth.*

"Take of Tragacanth, in powder, Gum Acacia, in powder, Starch, of each, *one ounce;* Refined Sugar, in powder, *three ounces.* Rub them well together." *Br.*

This is applicable to the general purposes of the demulcents; but is chiefly employed in Great Britain as a vehicle for heavy insoluble powders. The dose is from thirty grains to a drachm. W.

PYROXYLIN.

PYROXYLIN. *Br. Gun Cotton.*

"Take of Cotton *one ounce* [avoirdupois]; Sulphuric Acid, Nitric Acid, of each, *five fluidounces* [Imperial measure]. Mix the Acids in a porcelain mortar, immerse the Cotton in the mixture, and stir it for three minutes with a glass rod, until it is thoroughly wetted by the Acids. Transfer the Cotton to a vessel containing water, stir it well with a glass rod, decant the liquid, pour more water upon the mass, agitate again, and repeat the affusion, agitation, and decantation, until the washings cease to give a precipitate with chloride of barium. Drain the product on filtering paper, and dry in a water-bath." *Br.*

The adoption, by the Br. Pharmacopœia, of gun cotton as an officinal preparation, renders necessary, in accordance with the plan of the U. S. Dispensatory, the transferrence of the subject to this part of the work from the third part, where it has heretofore been treated. The following article, prepared by the late Dr. Bache, is accordingly brought hither from the position which it occupied in the twelfth edition. It will be perceived that the British process is essentially the same as that given below; the proportion of cotton to the acid employed being somewhat larger in the former.

Gun cotton, discovered by Schönbein of Bâle, in Switzerland, is conveniently prepared by the following process, given by Mr. Thomas Taylor, of London. Mix, in a glass vessel, 1½ fluidounces of nitric acid (sp. gr. 1·45) with an equal bulk of sulphuric acid, and, when the mixture has cooled, pour it upon 100 grains of fine cotton contained in a Wedgwood mortar, and, with a glass rod, imbue the cotton as quickly as possible with the acids. As soon as the cotton is completely saturated, pour off the superabundant liquid, and with the aid of the pestle, quickly press out as much of it from the cotton as possible. Then throw the cotton into a basin of water, wash it until it has not the slightest

acid taste, and dry it with a gentle heat. Gun cotton may be made with strong nitric acid alone; but, as this acid is not always of full strength, it is better to mix with it sulphuric acid, which acts by strengthening the nitric acid, from its affinity for water. It may also be formed by immersing the cotton in a mixture of nitre and sulphuric acid, and this is the mode adopted in the U. S. Pharmacopœia. (See *Collodium*, p. 1085.)

Properties, &c. Gun cotton has the appearance of ordinary cotton, but is harsh to the touch. It is perfectly insoluble in water, and nearly so in strong alcohol; but dissolves in large quantity in acetic ether. As ordinarily made for the purpose of explosion, it is insoluble in ether; but, when carefully and *freshly* prepared, with proper precautions, it dissolves in that menstruum, forming a powerfully adhesive liquid. (See *Collodium.*) According to Dr. J. H. Gladstone, of England, it is subject to spontaneous decomposition, if kept for some time. The same fact has been observed by Mr. James Beatson, of New York, and Prof. Procter, of Philadelphia. The specimen, observed by Prof. Procter to undergo decomposition, had not been well washed. The change is shown by the bottle, in which the gun cotton is kept, becoming full of nitrous acid vapour; and the substance is so far altered that it is no longer explosive or soluble in ether. M. Bouet states that the decomposition from exposure to light takes place sooner in that which has been prepared with nitre and sulphuric acid, than where the mixed acids have been used. He says that, with both, the sides and bottom of the bottle are nearly covered with crystals of oxalic acid. (See *Am. Journ. of Pharm.*, March, 1862, p. 187.) According to M. Béchamp, of Strasburg, the product is soluble in ether, if the cotton be immersed in a mixture of nitric and sulphuric acid, while still hot from their reaction; but not soluble, if the cotton be added to the mixture when cold. By treating gun cotton with protochloride of iron, M. Béchamp caused the disengagement of nitrous oxide gas, and gave the filaments a coating of oxide of iron, which was readily dissolved by muriatic acid. After this treatment the gun cotton was restored to its original state of cotton. (*Chem. Gaz.*, Jan. 1, 1854, p. 11.) When kindled, gun cotton flashes off like gunpowder, burning without residue. Its inflaming point is at 370° F. Dr. Marx makes it lower. It has been tried as a substitute for gunpowder in fire-arms; but from its strong bursting power, it has not been found to answer for this purpose. It appears, however, to be well adapted to rock blasting. Its composition has been variously given. Mr. Walter Crum, of Glasgow, makes its composition correspond with that of cellulose (cotton) $C_{12}H_{10}O_{10}$, in which three eqs. of water are replaced with three of nitric acid. On this supposition its formula is $C_{12}H_7O_7+3NO_5$. Porret and Teschemacher are of opinion that the cotton loses two eqs. of water, and gains four of nitric acid; so as to make its formula $C_{12}H_8O_8+4NO_5$. Another view is that three eqs. of the hydrogen are replaced by three eqs. of hyponitric acid, the oxygen which forms water with the hydrogen being derived from the nitric acid; so that the formula will be $C_{12}H_7 3NO_4O_{10}+3HO$. But the researches of Mr. Hadow, in 1864, seem to be more satisfactory. According to this chemist, who employs the new notation, the action of nitric acid on cotton is an example of substitution. Three eqs. of cotton, which represents cellulose $C_6H_{10}O_5$, enter together into action, giving up hydrogen, and receiving peroxide of nitrogen; the number of eqs. of hydrogen, replaced in the triple atom of cellulose, varying from nine to six according to the strength of the acid used. The highest of these substitution products is that in which nine eqs of hydrogen are replaced by nine eqs. of peroxide of nitrogen. This is trinitrocellulose, the pyroxylin or gun cotton of Schönbein, previously discovered by Pelouze, as early as 1836, in an impure state. The triple atom of cellulose $C_{18}H_{30}O_{15}$ gives up nine eqs. of its hydrogen, receiving in their place nine eqs. of peroxide of nitrogen, thus becoming $C_{18}\left\{\begin{matrix}H_{21}\\9NO_2\end{matrix}\right\}O_{15}$, equalling $3C_6\left\{\begin{matrix}H_7\\3NO_2\end{matrix}\right\}O_5$. (Prof. Abel, *Pharm. Journ. and Trans.*, 2d ser., vi. 71.) The above, however, though the formula for the gun cotton used for explosive purposes, which is insoluble in ether, is not that of the soluble pyroxylin used in preparing collodium, in which the substitution

of the peroxide of nitrogen is eight for the same number of hydrogen eqs., instead of nine for nine. For some interesting observations by MM. Pelouze and Maurey on the subject of gun cotton, and particularly in reference to the modifications in the mode of preparing it, introduced by General Lenk, of Austria, the reader is referred to an article contained in the *American Journal of Pharmacy* (Jan. 1865, p. 36). One of these modifications consists in giving to each fibre a coating of soluble glass, by dipping the gun cotton into a solution of silicate of soda. On exposure to the air, sufficient soda combines with carbonic acid to bring the silicate to the insoluble state, so that each fibre is enclosed in an impermeable covering, which is supposed to protect it from change. But MM. Pelouze and Maurey consider this coating less beneficial than supposed by General Lenk.

Off. Prep. Collodium, *Br.* B.

QUINIA.

Preparations of Quinia.

QUINIÆ SULPHAS. *U. S., Br. Sulphate of Quinia.*

"Take of Yellow Cinchona, in coarse powder, *forty-eight troyounces;* Muriatic Acid *three troyounces and a half;* Lime, in fine powder, *five troyounces;* Animal Charcoal, in fine powder, Sulphuric Acid, Alcohol, Water, Distilled Water, each, *a sufficient quantity.* Boil the Cinchona in thirteen pints of water mixed with one-third of the Muriatic Acid, and strain through muslin. Boil the residue twice successively with the same quantity of Water and Acid as before, and strain. Mix the decoctions, and, while the liquid is hot, gradually add the Lime, previously mixed with two pints of Water, stirring constantly, until the quinia is completely precipitated. Wash the precipitate with Distilled Water, and, having pressed, dried, and powdered it, digest it in boiling Alcohol. Pour off the liquid, and repeat the digestion several times, until the Alcohol is no longer rendered bitter. Mix the liquids, and distil off the Alcohol until a brown viscid mass remains. Upon this, transferred to a suitable vessel, pour four pints of Distilled Water, and, having heated the mixture to the boiling point, add as much Sulphuric Acid as may be necessary to dissolve the quinia. Then add a troyounce and a half of Animal Charcoal, boil the liquid for two minutes, filter while hot, and set it aside to crystallize. Should the liquid, before filtration, be entirely neutral, acidulate it very slightly with Sulphuric Acid; should it, on the contrary, change the colour of litmus paper to a bright red, add more Animal Charcoal. Separate the crystals from the liquid, dissolve them in boiling Distilled Water slightly acidulated with Sulphuric Acid, add a little Animal Charcoal, filter the solution, and set it aside to crystallize. Lastly, dry the crystals on bibulous paper with a gentle heat, and keep them in a well-stopped bottle. The mother-water may be made to yield an additional quantity of Sulphate of Quinia by precipitating the quinia with Water of Ammonia, and treating the precipitated alkaloid with Distilled Water, Sulphuric Acid, and Animal Charcoal, as before." *U. S.*

"Take of Yellow Cinchona Bark, in coarse powder, *one pound* [avoirdupois]; Hydrochloric Acid *three fluidounces* [Imperial measure]; Distilled Water *a sufficiency;* Solution of Soda *four pints* [Imp. meas.]; Dilute Sulphuric Acid *a sufficiency.* Dilute the Hydrochloric Acid with ten pints [Imp. meas.] of the Water. Place the Cinchona Bark in a porcelain basin, and add to it as much of the Diluted Hydrochloric Acid as will render it thoroughly moist. After maceration, with occasional stirring for twenty-four hours, place the bark in a displacement apparatus, and percolate with the Diluted Hydrochloric Acid, until the solution which drops through is nearly destitute of bitter taste. Into this liquid pour the Solution of Soda, agitate well, let the precipitate completely subside, decant the supernatant fluid, collect the precipitate on a filter, and wash it with cold Distilled Water, until the washings cease to have colour. Transfer the precipitate to a porcelain dish containing a pint [Imp. meas.] of Distilled Water, and, applying to this the heat of a water-

bath, gradually add Diluted Sulphuric Acid until very nearly the whole of the precipitate has been dissolved, and a neutral liquid has been obtained. Filter the solution while hot through paper, wash the filter with boiling Distilled Water, concentrate till a film forms on the surface of the solution, and set it aside to crystallise. The crystals should be dried on filtering paper without the application of heat." *Br.*

The present U. S. process, which is essentially that of the French Codex, is the same as that of the Pharmacopœia of 1850, but differs from the one originally adopted in the edition of 1830, in the use of muriatic instead of sulphuric acid for acidulating the water first employed, and in the greater minuteness of the details. Both this and the French Codex process are modifications of the plan originally proposed by M. Henry, jun., of Paris, which has been almost universally employed where alcohol is not too expensive. Henry's process, with all its details, may be found in former editions of this work. An explanation of the several directions given in the U. S. Pharmacopœia will be useful to the student, by enabling him to comprehend each step of the process.

The yellow bark (Calisaya, or royal yellow) is the variety selected, because this contains quinia in the largest proportion, and most free from admixture with cinchonia. The alkaloid exists in the bark combined with kinic acid, and probably also with one or more of the colouring principles, as suggested by M. Henry. As in this latter state it is difficult of solubility, if it be not insoluble in water, the whole of the quinia cannot be extracted from the bark by means of that liquid alone. Berzelius, however, attributes the difficulty of exhausting the bark to the circumstance that water converts the native neutral kinates into soluble superkinates which are dissolved, and insoluble subkinates which remain. By adding muriatic or sulphuric acid to the water in such quantities as to be in excess in relation to the quinia, the whole of the alkaloid combines with the acid to form a very soluble muriate or sulphate, in which state it exists, together with various impurities, in the decoctions procured by the first steps of the process. By the addition of lime to the filtered and mixed decoctions, the salt of quinia is decomposed, giving up its acid to the lime, while the quinia is liberated, and, being insoluble in water, is precipitated; the water retaining most of the impurities. If sulphuric acid was employed in the commencement of the process, sulphate of lime is deposited along with the quinia; but if muriatic acid was employed, the resulting chloride of calcium is retained in solution; and a reason is thus afforded for the preference of the latter acid. But, in either case, the excess of lime, and a compound formed of the lime and colouring matter, which is insoluble both in water and alcohol, are thrown down with the alkaloid. The precipitate having been washed in order to remove from it everything soluble in water, then pressed, dried and powdered; the next step is to separate the quinia from the insoluble impurities. This is accomplished by the repeated action of alcohol, which dissolves the former, and leaves most of the latter behind. The whole of the alkaloid having been abstracted, the alcoholic solution of quinia is then concentrated so as to afford a brown viscid mass, which is impure quinia. Portions of this may be reserved, if thought advisable, for the preparation of other salts of quinia. The mass is treated with boiling distilled water acidulated with sulphuric acid, which forms the officinal sulphate (disulphate of many chemists) with the quinia, and, being somewhat in excess, enables the salt to be readily dissolved. The animal charcoal now added should be the *unpurified* bone-black, the carbonate of lime contained in which neutralizes a portion of the sulphuric acid, and thus facilitates the crystallization of the sulphate of quinia when the solution cools. Should the quantity of the bone-black added be sufficient to render the solution quite neutral, so as in no degree to affect litmus paper, as much sulphuric acid should be added as will give the paper a slightly vinous tint; for otherwise the crystallization may commence before the liquor is completely filtered. If, on the contrary, the bone-black has been deficient, and the solution colours litmus paper cherry-red, more of that substance is to be added. This, however, is merely an incidental advantage of the

animal charcoal; its chief use being to decolorize the liquid. The second crystallization is necessary to obtain the salt of quinia free from colour; and sometimes it cannot be rendered perfectly white without a third. It is essential that the heat employed in drying the crystals should be gentle, in order to prevent their efflorescence. The small quantity of cinchonia contained in Calisaya bark is extracted along with the quinia; but, as the sulphate of the former is more soluble than that of the latter, it remains in the mother-liquors.*

According to M. Calvert, the proportion of sulphate of quinia obtained from bark is never certain when muriatic acid is employed as the solvent, and lime as the precipitant; for quinia is dissolved by a solution of chloride of calcium, and by lime-water; and a portion, therefore, remains in the liquid unprecipitated, which is greater when the lime employed is in excess. Having ascertained by trial that quinia is not dissolved by a solution of soda, and in scarcely appreciable proportion by chloride of sodium, he proposes to substitute this alkali for lime; first neutralizing the excess of acid by the carbonate, and then precipitating the quinia by caustic soda. (*Journ. de Pharm.*, 3e sér., ii. 388.)

The British process seems to be based on that of M. Rabourdin, of Orleans, published in the *Journal de Pharmacie* (Juin, 1861, p. 408), for which the advantages are claimed, that it does not require the use of alcohol, escapes the loss incurred in the ordinary process by the solvent property of lime, and is enabled, by the use of soda as the precipitant, to dispense with animal charcoal, and thereby avoid the waste incurred through its absorbent property. The soda in this process is employed not only as a precipitant, for which purpose a much smaller quantity would suffice, but in order to hold in solution the tannin, cinchonic red, and colouring and resinous matters, which it does without in the least dissolving the quinia. The precipitated quinia is thus obtained so far exempt from foreign matters, that it may be immediately converted into the sulphate without the necessity of using animal charcoal. From the precipitate by soda, M. Rabourdin obtains the quinia white and pure by treating it with a quantity of dilute muriatic acid insufficient to dissolve the whole of the alkaloid, whereby impurities are left behind, then filtering, and precipitating by ammonia. The same end is accomplished in the Br. process by the use of sulphuric acid. The residue of the precipitate may be reserved for future operations.

Pelletier proposed to substitute oil of turpentine for alcohol in the ordinary process for procuring sulphate of quinia. The impure quinia, precipitated by lime from the acidulous decoctions, after being washed, pressed, and dried, is digested with the oil, which dissolves the quinia. The solution thus obtained is agitated with water acidulated with sulphuric acid, by which the sulphate of quinia is formed. The oil separating, rises to the top, and is removed for future use; and the watery solution of the salt is evaporated, and treated as in the original process. A disadvantage, however, of this method is said to be, that the oil does not completely exhaust the precipitate of its quinia.

A similar process has been employed in England, *fusel oil* or *benzole* being substituted for oil of turpentine. In this instance, however, the new solvent is added to the impure quinia, without separation from the acidulated decoction from which it was precipitated by lime. The mixture being well agitated, the fusel oil or benzole dissolves the alkaloids, and, rising to the surface of the liquid, is drawn off by a syphon. The solution thus drawn off is treated as above with water acidulated with sulphuric acid, and the process is completed in the same manner. (See *Pharm. Journ.*, xiv. 29, 92, and 139.)

* Mr. Weightman, of the firm of Powers & Weightman, manufacturing chemists of this city, informs us that the following modification of the above process has been found practically advantageous in their laboratory. The tincture, obtained by acting with alcohol on the impure precipitated quinia, is neutralized with sulphuric acid in the distilling vessel; and the alcohol is then distilled off, leaving a viscid mass of impure sulphate, which is drawn off, and crystallizes on cooling. The mass thus obtained, having been expressed, is dissolved in boiling water, to which purified animal charcoal has been added. The solution is filtered while hot, and then allowed to cool and crystallize. Another solution and crystallization are required to get the sulphate of quinia quite pure and white. (*Note to the tenth edition.*)

According to the French Codex, 1000 parts of yellow bark ought to yield from 29 to 30 parts of sulphate of quinia, when treated by the process first described. Messrs. Powers & Weightman, who are probably among the largest manufacturers of sulphate of quinia in the world, inform us that they have usually obtained from 2·5 to 3 per cent. as an average product.

Sulphate of quinia may be obtained from other varieties of Peruvian bark by the above processes; and from some in considerable quantity; but most of them yield a much larger proportion of sulphate of cinchonia than the Calisaya; and this, being much more soluble than the sulphate of quinia, will remain dissolved in the residuary liquor after the crystallization of the latter. To obtain the *cinchonia* separate, the following method, originally suggested by Pelletier and Caventou, may be employed. Magnesia, lime, or a solution of potassa is added to the mother-waters in excess.* The cinchonia is precipitated, together with a portion of quinia which has remained in the solution, and with the excess of magnesia or lime, if one of these earths has been employed. The precipitate is collected on a filter, washed with hot water, then dried, and treated with boiling alcohol, which dissolves the organic alkalies. The alcoholic solution is filtered while hot, and the residue afterwards treated in the same manner with successive portions of alcohol, till quite exhausted. The solutions, having been mixed, are concentrated by the distillation of the alcohol, and allowed to cool, when they deposit cinchonia in the crystalline state. Successive evaporations and refrigerations afford new crops of crystals, and the process should be continued till no more can be obtained. The cinchonia thus procured, if impure, should be reconverted into a sulphate and treated as before, animal charcoal being employed to free it from colour. The quinia remaining in the mother-liquors, as it will not crystallize from alcohol, may be obtained by evaporation to dryness. To obtain the *sulphate of cinchonia*, mix the alkaloid with a small quantity of water, heat the mixture, and add gradually dilute sulphuric acid sufficient to saturate it; then boil with animal charcoal previously washed with muriatic acid, and filter the liquid while hot. Upon cooling it will deposit crystals of the sulphate, and, by repeated evaporation and crystallization, will yield all the salt which it holds in solution.†

* Soda is a better precipitant, as it is probably incapable of dissolving any of the alkaloid when employed in excess. In the U. S. formula for procuring sulphate of cinchonia from the mother-waters advantage has been taken of this fact. Hence the process differs from the one given in the text, both in using soda as the precipitant, and in forming the sulphate immediately from the precipitate, which is sufficiently pure for this treatment in consequence of the use of soda, instead of first separating the alkaloid by means of alcohol, and afterwards combining it with sulphuric acid. (See *Cinchoniæ Sulphas*, page 1084.) We retain the account of Pelletier and Caventou's process in the text, in order that the reader may have an opportunity of comparing them.

† A new mode of extracting quinia and other active vegetable principles has been proposed, which, if found as successful on trial as it is said to have been in the hands of its proposer, promises to supersede many of the processes now in use. From the experiments of M. Lebourdais, it would appear that purified animal charcoal has the property of extracting from many vegetable products not only their colouring, but their sapid principles also, and afterwards of yielding the active matter uncombined to boiling alcohol, from which it is obtained by evaporation. M. Lebourdais deprived Peruvian bark of all its soluble principles by repeated maceration in alcohol of 0·923, filtered the resulting liquors, removed the alcohol by distillation, and mixed the liquid residue with a decoction made by boiling the same bark twice in distilled water. Acetate of lead was added to precipitate the resinous matter; and the liquor, having been filtered, was made to pass slowly through purified animal charcoal, by which it was deprived of colour and taste. The charcoal was then washed, dried, and treated with alcohol of 0·848. The alcoholic solution thus obtained, upon being evaporated, yielded the quinia perfectly pure. (*Am. Journ. of Pharm.*, xxi. 92; from *Ann. de Chim. et de Phys.*) A chemist, however, who has tried this process, informs us that he has not found it to answer well in practice.

Mr. Clark proposes to prepare quinia by means of the fatty acids as follows. Having exhausted the bark as usual by acidulated water, he treats the solution with an alkaline carbonate so long as a precipitate is produced, then adds a little stearic acid, and boils the whole. The fatty acid melts, floats on the surface, and there attracts the quinia and cinchonia, forming a kind of insoluble soap, while the precipitate and liquid become black. On cooling, the fatty matter coagulates, and, on being withdrawn and boiled in water so

When barks containing the newly discovered alkaloids *cinchonidia* and *quinidia* (see *page* 301) are used, as their sulphates are much more soluble than that

long as this remains limpid, and then treated with boiling acidulated water, yields the quinia and cinchonia to the acid. The hot solution, being neutralized by an alkali, deposits a brown matter, which is to be separated by filtration, and on cooling yields the sulphate of the two alkaloids in a crystalline state. The quinia and cinchonia can then be separated in the ordinary mode. (See *Journ. de Pharm.*, Dec. 1861, p. 463.)

We have been told that considerable quantities of a preparation have been imported from South America, consisting of a mixture of the alkaloids of bark in an impure state, obtained by forming acidulated decoctions of bark, precipitating with lime, treating the precipitate with alcohol, and evaporating the alcoholic solution. From this material the sulphates of quinia and cinchonia have been prepared on a large scale. It has sometimes yielded 25 per cent. of quinia converted into sulphate, and more than an equal quantity of cinchonia. (*Note to the eighth and tenth editions.*)

Quinoidine. Precipitated Extract of Bark. Amorphous Quinia. Cinchonicia and Quinicia of Pasteur. Upon the evaporation of the mother-liquor left after the crystallization of sulphate of quinia in the preparation of that salt, a dark-coloured substance is obtained, having the appearance of an extract. This was habitually employed by the late Dr. Emlen and one of the authors of this work, so early as about the year 1824, in the cure of intermittent fever, in which it proved equally effectual with the pure sulphate, though only about half as strong. It was adopted in the edition of the U. S. Pharmacopœia for 1830 under the name of "*impure sulphate of quinia*," but was abandoned in the edition of 1840, on account of the difficulty of ascertaining its purity. Sertürner supposed that he had discovered a new alkaline principle in this product; but his conclusions were invalidated by the experiments of MM. Henry and Delondre, which went to prove that the alkaline matter contained in it consisted of quinia and cinchonia, obscured by admixture with a yellowish substance that interfered with their crystallization. Nevertheless, under the name of *quinoidine* or *chinoidine*, given to the supposed new alkaloid by Sertürner, there has been long employed in Europe a substance precipitated from the mother-liquor of sulphate of quinia by means of an alkaline carbonate, having a yellowish-white or brownish colour, and, when moderately heated, agglutinating into a mass of a resinous appearance. This substance was found by Dr. F. L. Winckler to contain an uncrystallizable alkaline principle, having the same combining weight as quinia, and differing from that alkaloid only in the want of the property of crystallization, and in forming uncrystallizable salts with the acids. (*Pharm. Cent. Blatt*, May, 1847, p. 310.) Liebig afterwards proved it to be identical in composition with ordinary quinia, to which he considered it as bearing the same relation that uncrystallizable sugar bears to the crystallizable. Pasteur has found that ordinary quinoidine, or amorphous quinia, consists of two alkaloids, derivatives from quinia and cinchonia, with which they are respectively isomeric, though differing in being uncrystallizable, and named, in view of their origin, *quinicia* and *cinchonicia*. The pure amorphous quinia of Liebig is the former of these alkaloids. (See *page* 303.) This substance has been found equally effectual with quinia in the cure of intermittents. In an economical point of view, it is highly important that it should be employed. It is sometimes sold under the name of *precipitated extract of bark;* and there can be little doubt that it enters into other preparations, which, under the name of extract of bark, have been put forth as peculiarly valuable for the cure of intermittents. It must not be confounded with the substance obtained by evaporating the mother-liquors, which is of uncertain composition and strength. The chief objection to it is its liability to adulteration. The *amorphous quinia*, as Liebig calls it, is entirely soluble in dilute sulphuric acid and in alcohol; and, if its solution in a dilute acid yield upon the addition of ammonia exactly as much precipitate as there was of the original substance dissolved, it may be considered pure. (See *Am. Journ. of Pharm.*, xviii. 181.) We have been informed that, in an extensive chemical manufacturing establishment in Philadelphia, since the introduction of steam heat, the loss by quinoidine in the preparation of sulphate of quinia has much diminished, showing the agency of heat in converting the crystallizable into the uncrystallizable salt.

As commercial quinoidine is often very impure, sometimes, according to the observations of M. de Vry, containing as much as 35 per cent. of foreign matters, a satisfactory method of purifying it becomes important. The following has been proposed by M. de Vry, founded on the observation of M. Pasteur, that 9 parts of quinoidine, rubbed for a long time in a mortar with a dilute solution of 2 parts of neutral oxalate of ammonia, are at length completely dissolved, with the escape of the ammonia, and entire separation of impurities. M. de Vry boils in an iron vessel 9 parts of quinoidine with a weak solution of 2 parts of oxalate of ammonia, until ammonia ceases to escape. As the insoluble matter attaches itself in places to the surface of the vessel, he adds from time to time distilled water so as to cover this matter during the boiling. As soon as ammonia is no longer disengaged, he allows the liquor to become quite cool, and ascertains if it is made turbid by the addition of water. In this case he dilutes the solution with water, then filters, and precipitates in a capsule with an excess of solution of caustic soda. The tenacious precipitate which forms may be collected, by means of a gentle heat, in the bottom of the capsule.

of quinia, it follows that, in the mother-waters left after the crystallization of sulphate of quinia, there will be found a portion of sulphate of cinchonidia or quinidia, or of both. In fact, there is generally, under these circumstances, more or less of the sulphates of the four alkaloids, quinia, cinchonia, quinidia, and cinchonidia, all of which are contained in many barks; and, besides these, a portion of amorphous alkaloid, incapable of crystallization, probably resulting, in part at least, from the heat employed in the process. These may in a great degree be separated through their different solubilities in water. Sulphate of quinia being least soluble will first crystallize, afterwards the salt of cinchonidia or quinidia, and finally that of cinchonia, which is the most soluble of the four; while the uncrystallizable salt will remain in solution, and may be obtained in the amorphous state by evaporation to dryness.

Properties. Sulphate of quinia is in fine silky, slightly flexible, needle-shaped crystals, interlaced among one another, or grouped in small star-like tufts. Its taste is intensely bitter, resembling that of the yellow bark. It effloresces slightly on exposure to the air, and, at a moderate heat, loses its crystalline form in consequence of the escape of its water of crystallization. At the temperature of 212° it becomes luminous, especially when rubbed. At about 240° it melts, assuming the appearance of wax. It is very slightly soluble in cold water, requiring, according to M. Baup, 740 parts at 54° F. for solution; while at the boiling point it is dissolved in 30 parts of water, which deposits it upon cooling.* Its cold solution is opalescent.† It is soluble in about 60 parts of cold alcohol of 0·835, but only to a very small extent in ether. The diluted acids, even tartaric and oxalic acids in excess, dissolve it with great facility. With an additional equivalent of sulphuric acid it forms another sulphate, which is more soluble in water than the officinal salt, and crystallizes from its solution with much greater difficulty. This is now considered by many as strictly neutral, and therefore entitled to the name of sulphate of quinia; while the officinal salt is thought to contain two equivalents of base to one of acid, and is therefore a *subsulphate or disulphate of quinia.* The latter name was adopted by the London College, and has been much used by chemical writers. In the U. S., Dublin, and Edinburgh Pharmacopœias, as well as in the French Codex, the name of sulphate of quinia, originally given to the officinal salt, under the impression that it was neutral, was retained; and it has been assumed in the new British Pharmacopœia. Hence has arisen a confusion of nomenclature, which must be embarrassing to the student. Our own impressions are in favour of the higher number of the equivalent of quinia, and consequently of the view which considers the officinal name of sulphate of quinia

The clear alkaline liquid is then decanted, and the precipitated quinoidine washed repeatedly with distilled water. Thus purified, being still adhesive, it is exposed for some time to a heat of 212° to 230°, at which it parts with the water it contained, and becomes, after cooling, hard and friable. The oxalate of ammonia is used in order to get rid of lime, which is a frequent impurity in quinoidine. (*Journ. de Pharm.*, 4e sér., iv. 50.) —*Note to the thirteenth edition.*

* M. Calloud has ascertained that the solubility of sulphate of quinia is much affected by certain salts. While it is increased by muriate of ammonia, nitrate of potassa, and chloride of sodium, it is diminished by the sulphates of soda and magnesia. Sulphate of quinia is decomposed wholly or in part by bicarbonate and phosphate of soda. (*Pharm. Journ.*, June, 1860, p. 609.)

† *Animal Quinoidine.* The peculiar appearance characterizing solutions of quinia, even when extremely feeble, called opalescence or fluorescence, was observed by Dr. H. Bence Jones in the fluids of animals, after having taken quinia, and was subsequently noticed, as an ordinary result, even when no quinia had been given, though in a less degree. This led Dr. Jones to the supposition that there existed normally in the animal system a substance identical or analogous with quinia, which he called *animal quinoidine.* The fluids exhibiting this phenomenon answered to other tests of quinia; and, though this substance could not be isolated, probably in consequence of its extremely minute proportion, the evidence seemed very strong in favour of the idea, that a principle closely resembling quinia exists normally in the human system. A curious fact, in connection with this subject, is that the substance in question ceases apparently to exist in the system in a state of fever. This discovery opens a wide field for observation to the physiologist and pathologist; but at present would scarcely seem to fall within the province of the pharmaceutist. (*Note to the thirteenth edition.*)

as properly representing the composition of the salt. According to M. Baup, the higher sulphate, formerly called *supersulphate*, and still considered by many if not most chemists as the *bisulphate*, is soluble in 11 parts of water at 54° F., and in its own water of crystallization at the boiling point It is very soluble in diluted, and somewhat less so in absolute alcohol. It may be obtained by adding to a boiling concentrated solution of the ordinary sulphate, as much sulphuric acid as already exists in the salt, and then evaporating the solution.

Composition. The officinal sulphate of quinia, the disulphate of some chemists, is the only one used in medicine, and to this we have allusion in the present work, whenever sulphate of quinia is mentioned without any distinguishing epithet. In the crystalline form it consists, if regarded as neutral, of one eq. of quinia 324, one of sulphuric acid 40, and eight eqs. of water 72 = 436; but if considered, in accordance with Liebig's views, as a subsulphate or disulphate, of two eqs. of quinia (each 162), one of sulphuric acid, and eight of water; the whole eq. of the salt being, of course, the same in either case. On exposure to the air, or to a heat of 212°, it effloresces, losing one-half of its water of crystallization; and at 240° it loses one-half of the remainder, retaining two eqs. or about 4 per cent. of water, of which it cannot be deprived without decomposition. (*Phillips.*)*

* *Iodide of Sulphate of Quinia, &c.* This remarkable compound of officinal sulphate of quinia was discovered by Dr. Wm. Bird Herapath, of Bristol, England, who also investigated its singular optical properties. If to a solution of sulphate of quinia in a mixture of acetic acid and diluted alcohol, tincture of iodine be added by drops, and the mixture kept at 130° F. until perfect solution takes place, upon the cooling of the liquid, crystals will gradually form, which Dr. Herapath has found to consist of iodine, quinia, and sulphuric acid, probably combined in the state of *sulphate of iodo-quinia*. To obtain fine crystals various precautions are necessary, for which the reader is referred to the paper of Dr. Herapath. The crystals are of a brilliant emerald-green when viewed by reflected light, but almost colourless by transmitted light, and present a curious play of colours under varying circumstances of position. Their shape is very diversified, but traceable to the rhombic prism. They are dissolved by heated acetic acid and heated alcohol, and deposited on cooling. Their most remarkable property is that of polarizing light, in which they are equal if not superior to the tourmaline, for which they may be substituted with advantage in experiments in this branch of optics. (*Pharm. Journ.*, xi. 448 and 449, and xiii. 378. See also *Am. Journ. of Pharm.*, xxvi. 18.) From subsequent experiments of Dr. Herapath, it appears that the other cinchona alkaloids form similar salts with iodine; so that crystals may be obtained of the *sulphates of iodo-quinidia*, *iodo-cinchonia*, and *iodo-cinchonidia*, as well as of iodo-quinia. But the reader will note that the nomenclature of the alkaloids adopted by Dr. Herapath differs from that of Pasteur, and unfortunately we think, as that of Pasteur is based on the analogies of the alkaloids. The quinia and cinchonia are the same with both, but the quinidia of Pasteur is the cinchonidia of Herapath, and vice versa. In the following observations the nomenclature of Dr. Herapath is used, in justice to that writer. It appears that, of these different compounds, there is a close analogy in crystalline forms between the iodo-quinia and iodo-cinchonidia salts on the one hand, and the iodo-cinchonia and iodo-quinidia salts on the other, while between the two twin sets there is a decided difference; so that there is no difficulty in deciding whether a quinia salt contains quinidia or cinchonia, or a cinchonia salt cinchonidia or quinia, yet it may not be so easy to discriminate between the salts of analogous forms. Nevertheless there are sufficient points of dissimilarity to enable a correct diagnosis to be made. It is not by their chemical characters that these iodo-salts can be discriminated; though the cinchonia and quinidia salts dissolve with greater difficulty than the others in consequence of their greater thickness, and less extent of surface. The crystals of the *cinchonidia* salt (*quinidia*, Pasteur), like those of the sulphate of iodo-quinia, are derived from the rhombic prism, but differ in certain points which we have not space to detail, and in reference to which we must be content to refer to Dr. Herapath's paper. They are distinguishable to the practised eye by their different tint with reflected and transmitted light. But these salts differ greatly from the *iodo-cinchonia* and *iodo-quinidia* (*iodo-cinchonidia*, Pasteur) *sulphates*. The crystals of the latter of these salts are long quadrilateral acicular prisms, of a deep-ruby or garnet-red colour, with bluish-violet or light-purplish reflection tints, or they have the form of thin plates, or long, flat, acicular prisms, which, when thin, transmit a pure yellow, but if thicker, a reddish colour tinged with brown. The analogous *iodo-cinchonia sulphate* is in long, acicular, quadrilateral prisms, of a deep purplish-black colour; and in relation to transmitted light also closely resembles the preceding. All these iodo-salts have double refractive properties. Dr. Herapath gives the following as their composition; 1. *sulphate of iodo-quinia*, $C_{57}H_{33}N_2O_5,I_2+2SO_3HO+5HO=840$; 2. *sulphate of iodo-cinchonidia* (*iodo-quinia*, Pasteur), $C_{57}H_{33}N_2O_5,I_3+2SO_3HO+5HO=967$; 3. *sulphate of iodo-cinchonia*, $C_{35}H_{19}N_2O_{21}I_3+SO_3$

Incompatibles and Tests. Sulphate of quinia is decomposed by the alkalies, their carbonates, and the alkaline earths. In solution, it affords white precipitates with potassa, soda, and ammonia, which are partly soluble in an excess of alkali. It is also precipitated by astringent infusions, the tannic acid of which forms a white insoluble compound with quinia. The soluble salts of lead and of baryta occasion precipitates; and that produced by the salts of baryta is insoluble in the acids. The soluble salts of oxalic, tartaric, and gallic acids occasion more or less precipitation with solution of sulphate of quinia without excess of acid; and Mr. J. M. Maisch has ascertained the same to be true of the acetates. (*Am. Journ. of Pharm.*, xxvii. 97.) A freshly prepared solution of chlorine, added to a solution of sulphate of quinia, and followed by the addition of water of ammonia, occasions an emerald-green colour, and, in certain proportions, the deposition of a green precipitate. If, previously to the use of ammonia, a concentrated solution of ferrocyanide of potassium be added, a dark-red colour is produced, which persists for several hours, but ultimately passes into green. This does not take place with cinchonia; and, though sulphate of quinidia gives the same red colour, this does not disappear as with the salt of quinia, but is persistent. (Schwartzer, *Journ. de Pharm.*, 4e sér., iii. 475.) Sulphate of quinia gives a reddish-brown precipitate with iodine dissolved in a solution of iodide of potassium.

Adulterations. Sulphate of quinia has often been adulterated. The effects of adulteration may be produced by the variable quantity of water which sulphate of quinia may contain, without any observable alteration in its sensible properties. MM. Millon and Commaille, having exposed sulphate of quinia to a very moist atmosphere, at the temperature of about 62° F., found it always to increase in weight; so that a specimen of the salt, previously deprived of all its water capable of being separated by heat, had in five days absorbed 28·77 per cent. of water, and another specimen dried after its precipitation simply by draining, and supposed to contain 18 per cent. of water, had in ten days absorbed 14 per cent. more, making its whole percentage of water 32, or about one-third of its weight. (*Journ. de Pharm.*, Nov. 1862, p. 379.) This is an important fact, and will explain, to

$HO + 6HO = 757$; 4. *sulphate of iodo-quinidia* (*iodo-cinchonidia*, Pasteur), $C_{35}H_{19}N_2O_4,I_2 + SO_3HO + 5HO = 637$. When the acid sulphates of the mixed alkaloids, quinia, quinidia, cinchonia, and cinchonidia, are dissolved in dilute alcohol, and the solution heated to from 80° to 120°, tincture of iodine readily separates the quinia salt; further treatment in the same manner separates the cinchonidia (*quinidia*, Pasteur) salt, more or less mixed with the preceding; still further treatment, the quinidia (*cinchonidia*, Pasteur) salt with its well-marked characters; and the cinchonia salt, being by far the most soluble, is the last to appear, but if in large proportion will be mixed with the quinidia (cinchonidia) salt. Cinchonidia (quinidia) may thus be readily detected in cinchonia, which might otherwise be considered pure. In like manner a mixture of quinidia (cinchonidia) with quinia is easily made evident. (See *Am. Journ. of Pharm.*, May, 1858, p. 246; from *Pharm. Journ.*, March, 1858.)

The rotating powers of the cinchonia salts in reference to polarized light also afford means of distinguishing them, to those who may possess the requisite apparatus. Allusion has been made to these properties under the several alkaloids in the first part of the work. It may be proper to say here that quinia and cinchonidia (*Pasteur*) are strongly lævogyrate, while cinchonia and quinidia (*Pasteur*) are strongly dextrogyrate, and quinicia and cinchonicia slightly dextrogyrate.

We may here, moreover, refer to another test, requiring instrumental aid, offered by Mr. W. Walter Stoddart. If a drop of a solution of sulphocyanide of potassium be added to a saturated and neutral solution of a suspected specimen of sulphate of quinia, and the mixture be observed, by means of the microscope, if cinchonia or quinidia (cinchonidia, *Pasteur*) be present, characteristic crystals of sulphocyanide of these alkaloids will be noticed, wholly distinct in shape from those of sulphocyanide of quinia formed at the same time. (*Pharm. Journ.*, Oct. 1864, p. 155, and *Am. Journ. of Pharm.*, Jan. 1865, p. 41.)

Still another newly discovered mode of distinguishing between quinia and cinchonia, suggested by M. Palm, is one based on the influence of polysulphuret of potassium on those alkaloids. If a solution of this reagent be added to a boiling solution of a salt of quinia, this, however small may be its proportion, will be thrown down as a red, viscid mass, which hardens upon cooling, and assumes a resinous appearance; whereas cinchonia is separated as a white powder containing sulphur. The polysulphuret is prepared by boiling a solution of potassa with an excess of sulphur. (*Journ. de Pharm.*, Mai, 1864, p. 459.)—*Notes to the eleventh and twelfth editions.*

some extent, the frequently variable effects from apparently the same quantity of the salt. It is easy to detect and to obviate this natural sophistication by exposing a suspected specimen to a heat of 212°. The loss of weight will indicate the quantity of water, not essential to the salt. Sulphate of lime, and other alkaline or earthy salts, gum, sugar, mannite, starch, stearin or margarin, caffein, salicin, phloridzin, and the sulphates of cinchonia and other cinchona alkaloids, are among the substances which are said to have been fraudulently added. By attending to the degree of solubility of the sulphate in different menstrua, and to its chemical relations with other substances already described, there can be little difficulty in detecting these adulterations. The presence of any mineral substance, not readily volatilizable, may be at once ascertained by exposing the salt to a red heat, which will completely dissipate the sulphate of quinia, leaving the mineral behind. A volatile ammoniacal salt may be detected by the smell of ammonia emitted upon the addition of potassa. The absence of organic substances may be inferred, if pure cold concentrated sulphuric acid forms a colourless solution. Gum and starch are left behind by alcohol, and fatty matters by water acidulated with sulphuric acid. Sugar and mannite cause a solution of the salt in acidulated water to have a sweet taste, after the precipitation of the quinia by an alkaline carbonate. Salicin imparts the property of becoming red upon the contact of sulphuric acid; but, according to Pelletier, this change of colour does not take place, unless the proportion of salicin exceeds one-tenth. If only in this proportion, the salicin must be isolated. To 1 part of the suspected salt, 6 parts of concentrated sulphuric acid may be added, and to the brown liquid which results, 125 parts of water. The salicin is thus separated, and may be obtained by filtration, in the form of a bitter, white powder, becoming bright red with sulphuric acid. (See *Am. Journ. of Pharm.*, xvii. 156.)* Caffein alters the solubility of the medicine in different menstrua. According to M. Calvert, a saturated solution of sulphate of quinia in cold water gives, with a solution of chloride of lime, a precipitate soluble in an excess of the latter; while a solution of sulphate of cinchonia of the same strength, treated in the same manner, gives a precipitate which is insoluble in a great excess of the reagent. The same effect is produced with lime-water, and solution of ammonia; and solution of chloride of calcium, while it furnishes a precipitate with a solution of sulphate of cinchonia, yields none with a solution of sulphate of quinia. (*Journ. de Pharm.*, 3e sér., ii. 394.)† The

* For a method of detecting the presence of salicin by the saliretin produced, and of determining the proportion of salicin, by means of the glucose resulting, when the salicin is decomposed by muriatic acid, see a communication by M. Bourlier in the *Journal de Pharmacie* (Juillet, 1859, p. 34). Another method of detecting minute proportions of salicin, proposed by Parrot, is by means of chromic acid. The mode of proceeding is as follows. The suspected salt is put with a little water into a small retort, to which are added two cubic centimetres of sulphuric acid diluted with 4 parts of water, and 4 cubic centimetres of a concentrated solution of bichromate of potassa. The retort is connected with a phial by means of a tube plunging into a dozen grammes of distilled water contained in the phial; and the heat of a spirit lamp is applied. In three or four minutes, if salicin is present, hydrate of salicyl distils over, and the water in the receiver assumes a beautiful violet colour on the addition of a drop or two of solution of perchloride of iron. (*Ibid.*, Dec. 1867, p. 450.)

† Liebig's test of the presence of cinchonia is perhaps the simplest. Rub together fifteen grains of the suspected salt and two ounces of solution of ammonia, put the mixture into a flask, add two ounces of ether, and shake frequently. The quinia liberated by the ammonia is dissolved by the ether, while any cinchonia that may be present remains undissolved, floating between the ethereal solution above and the ammoniacal beneath. But M. O. Henry has shown that cinchonia is slightly soluble in ammonia, so that a small portion might escape detection. It has, therefore, been proposed to modify the test by heating the mixture of the suspected salt and ammonia, so as almost entirely to drive off the excess of this alkali, and then to add the ether. If the liquid now remain quite transparent, without any turbid layer between the upper and lower stratum, it may be inferred that no cinchonia is present. For papers on this subject, see *Journ. de Pharm.* (3e sér., xiii. 102, xvi. 327, and xxi. 284), and *Am. Journ. of Pharm.* (xx. 231, and xxiv. 166).

The precise quantities originally proposed in Liebig's test were one gramme of sulphate of quinia, ten grammes of ether, and two grammes of caustic ammonia. But M. Roger has proved that, with these proportions, in order that the test may succeed, it is necessary to

Edinburgh College gave the following mode of testing the purity of sulphate of quinia. "A solution of ten grains in a fluidounce of distilled water and two or three drops of sulphuric acid, if decomposed by a solution of half an ounce of carbonate of soda in two waters [twice its weight of water], and heated till the precipitate shrinks and fuses, yields on cooling a solid mass, which when dry weighs 7·4 grains, and in powder dissolves entirely in solution of oxalic acid." According to the London College, "100 grains dissolved in diluted hydrochloric acid, yield, on the addition of chloride of barium, 26·6 grains of sulphate of baryta, dried at a red heat." Though sulphate of quinia, as prepared for use, frequently contains a portion of one or more of the recently discovered cinchona alkaloids, the salt is probably not less efficacious on that account; as these alkaloids have been shown to possess identical therapeutical properties with those of quinia, and to be little inferior in strength, if at all, in relation to most of them.

Medical Properties and Uses. Sulphate of quinia produces upon the system, so far as we are enabled to judge by observation, the same effects as Peruvian bark, without being so apt to nauseate and oppress the stomach. (See *Cinchona.*) Its effects upon the brain are even more striking than those of cinchona, probably because it is given in larger proportional doses. Even in ordinary doses, it often produces considerable cerebral disturbance, evinced by a feeling of tightness or distension in the head, ringing, buzzing, or roaring in the ears, hardness of hearing, &c. Some individuals are more liable to these effects than others, and in some even small doses produce them. A certain degree of this observable action on the brain is rather desirable than otherwise, as an evidence that the medicine is affecting the system. In very large quantities, as from a scruple to a drachm or more, besides the phenomena mentioned, it has been observed to occasion severe headache, vertigo, deafness, diminution or loss of sight, dilated and immovable pupil, loss of speech, general tremblings, intoxication or delirium, coma, and great prostration. In some instances the pulse has been remarkably diminished in frequency, down to fifty or even less in the minute. In an instance recorded by Giacomini, in which a man took by mistake about three drachms, the patient became insensible, and some hours afterwards was found by the physician in a state of general prostration, from which he recovered under the use of laudanum and aromatic waters. (*Ann. de Thérap.*, A. D. 1843, p. 176.) Besides its effects on the brain, sulphate of quinia sometimes occasions great gastric and intestinal irritation, marked by oppression of stomach, nausea, abdominal pains, vomiting, and purging. In general these effects of excessive doses gradually pass off, although partial deafness often continues for several days, and sometimes much longer. It is even said that permanent deafness has

use ether containing alcohol, which is the case with commercial ether. Of pure ether 25 grammes would be requisite for the perfect solution of the quinia from a gramme of the sulphate, while 10 grammes of ether containing but two per cent. of alcohol will produce the same effect. In these proportions the presence of quinidia as well as of cinchonia would be detected. (Roger, *Journ. de Pharm.*, Mars, 1862, p. 204.) For a method of detecting the presence of *quinidia* in sulphate of quinia, the reader is referred to a note in the first part of this work, *page* 307.

For an elaborate account by Dr. G. Kerner of the cinchona alkaloids, of which he believes that there are several not yet fully determined, and of the method of testing commercial sulphate of quinia for the other alkaloids with which it is apt to be contaminated, we must be content with referring to the paper itself, which appeared in the *Zeitschrift für Analytische Chemie*, but a translation of which will be found in the *Pharm. Journ.* for July, 1862, and in the *Am. Journ. of Pharm.* (Sept. 1862, p. 417). Perhaps the most important practical result of these investigations is the suggestion of a new test by which the alkaloids may be distinguished; their solubilities, namely, in water of ammonia of given strength which, according to Dr. Kerner, are more fixed and reliable than their solubilities respectively in water, or other ordinary solvent. The mode of application is by taking a certain quantity of the sulphate of the alkaloid dissolved in a certain quantity of water, and then adding the water of ammonia gradually until the alkaloid precipitated is redissolved; and the quantity of the ammoniacal liquid necessary to produce this effect indicates inversely the solubility of the alkaloid. Quinidia requires from 10 to 11 times more of the ammoniacal liquid than quinia, cinchonidia from 12 to 13 times more; while cinchonia is not dissolved by a much larger proportion than is required by either of the others, and though, when mixed in very small proportion with quinia it is dissolved at first, yet it afterwards separates on standing. (*Note to the twelfth edition.*)

resulted. Though sulphate of quinia has been proved by the experiments of Dr. Baldwin, of Montgomery, Alabama, to be fatal to dogs, if prevented from vomiting by a ligature round the œsophagus, in quantities varying from fifteen or twenty grains to two drachms, with the symptoms of narcotic poisoning; yet we have seen no well authenticated case of death from its direct action on the perfectly healthy human subject. Given largely in disease, it has repeatedly caused fatal results, not so much however by its peculiar action, as by co-operating with the disease in establishing intense local irritation or inflammation, especially in the brain. Though capable, therefore, of doing mischief if improperly used, sulphate of quinia can scarcely be ranked among the poisons.

From its occasional effect in diminishing the frequency of the pulse and the general strength, it has been supposed to be essentially sedative in large doses. Such an opinion, unless well founded, might lead to hazardous practice. The probability is that the apparently sedative effect upon the circulation arises from an overwhelming stimulant influence upon the cerebral centres, whereby the system is deprived of the support of these centres, and the heart's action is depressed with other organic functions. Similar effects may be obtained from excessive doses of most of the cerebral stimulants. Examination of the brain in the lower animals, after death from quinia, has shown great congestion of that organ and its membranes, and even meningitis. (See *Am. Journ. of Med. Sci.*, xix. 197.) In the present state of our knowledge, therefore, it is safest to consider sulphate of quinia as a direct and powerful stimulant to the brain. It probably operates through the circulation, as there is no doubt that it is absorbed, the alkaloid having been found unchanged in the urine. Quinia is said to be a specific poison for the lower organisms (*N. Y. Med. Journ.*, Sept., 1868, p. 550; from *Schmidt's Jahrbuch*); and some would be disposed to find in this property an explanation of its efficacy in miasmatic diseases.

Sulphate of quinia may be substituted for cinchona in all diseases to which the latter is applicable; and, in the treatment of intermittents, has almost entirely superseded the bark. It has the advantage over that remedy, not only that it is more easily administered in large doses, and more readily retained by the stomach, but that in cases which require an impression to be made through the rectum or the skin, it is much more effectual; because, from the smallness of its bulk, it is more readily retained in the former case, and more speedily absorbed in the latter. Still we cannot be certain that there are not other active principles in bark besides the alkaloids, which are closely analogous in their effects, nor that the mode of combination in which these principles exist may not in some measure modify their therapeutic action. Until this question is solved, we may resort to the bark if the sulphate of quinia should not answer the ends in view; and instances have occurred, under our own notice, in which it has proved successful in intermittents after the salt had failed.

A novel use of sulphate of quinia is for preservation from the attacks of cholera. Dr. La Roche, of Kurnik, recommends it strongly as a prophylactic against that disease, considering it not less efficacious than vaccination against smallpox. On the approach of the epidemic, two grains are taken every hour until the quantity amounts to twenty-four grains, after which two grains are taken three times a day for three weeks, and, finally, the same dose night and morning until the epidemic disappears. (*Med. and Surg. Reporter*, Aug. 15, 1868, p. 134; from *Ph. Centralhalle.*)

Sulphate of quinia may be given in pill or solution, or suspended in water by the intervention of syrup and mucilage. The form of pill is usually preferred. (See *Pilulæ Quiniæ Sulphatis.*) The solution may be readily effected by the addition of a little acid of almost any kind to the water. Eight grains of the sulphate will dissolve in a fluidounce of water, acidulated with about twelve minims of the diluted sulphuric acid, or aromatic sulphuric acid of the Pharmacopœias; and this is the most eligible mode of exhibiting the medicine in the liquid form. The addition of a small proportion of sulphate of morphia or of laudanum will often be found advantageous when the stomach is disposed to be

sickened, or the bowels to be disturbed by the quinia. Mr. J. S. Blockey ascertained that glycerin will, if gently heated, dissolve eight grains of the sulphate in each fluidrachm, and may therefore be conveniently used as a vehicle. (*Lond. Chemist*, Sept. 1857.) Dr. R. H. Thomas, of Baltimore, found that one part of tannic acid will deprive five parts of sulphate of quinia of bitterness, without impairing its medicinal efficacy. (*Am. Journ. of Med. Sci.*, N. S., xix. 541.) It is obvious that tannate of quinia is thus formed; and as this, though insoluble in water, is readily dissolved in dilute acids, and consequently in the gastric liquor when acid, there can be no doubt that it will generally prove efficacious. It may, however, happen that the stomach may be quite free from acid, and that the operation of this salt may prove less certain than that of the sulphate; and such is asserted to have been the case in some instances; but a little lemonade taken after the medicine would probably obviate the difficulty.

Twelve grains of sulphate of quinia are equivalent to about an ounce of good bark. The dose varies exceedingly, according to the circumstances of the patient, and the object to be accomplished. As a tonic simply, a grain may be given three or four times a day, or more frequently in acute cases. In intermittents, from twelve to twenty-four grains should be given between the paroxysms, divided into smaller or larger doses according to the condition of the stomach, or the length of the intermission. From one to four grains may be given at once, and some even advise the whole amount. In malignant intermittents and remittents, the quantity may be increased to thirty grains or even a drachm between the paroxysms. M. Maillot gave one hundred and twenty-eight grains, in the course of a few hours, in a case of malignant fever occurring in northern Africa, with the happiest results. The caution, however, is necessary, not to employ this heroic practice against easily conquerable diseases. Very large doses of the sulphate have recently been given in acute rheumatism, and with great asserted success; but the occurrence of at least one fatal case from inflammation of the brain should lead to some hesitation in this employment of the remedy. When the stomach will not retain the medicine, it may be administered with nearly as much efficacy by enema; from six to twelve grains, with two fluidounces of liquid starch, and from twenty to forty drops of laudanum, being injected into the rectum, in ordinary cases, every six hours. Should circumstances render this mode of application impracticable, an equal quantity, diluted with arrow-root or other mild powder, may be sprinkled, at the same intervals, upon a blistered surface denuded of the cuticle. The epigastrium, or the inside of the thighs and arms, would be the proper place for the blister. The sulphate has also been employed by friction in the form of ointment, in cases of malignant intermittent. The ointment should be made by incorporating a saturated alcoholic solution of the salt with lard, and should be applied to the inside of the thighs and arms. It is said that quinia is more readily absorbed when united with a fatty acid. This union may be effected by mixing solutions of soap and of a salt of quinia. The quinia soap is precipitated. Purified oleic acid will dissolve one-tenth of its weight of sulphate of quinia, if aided by a gentle heat; and this solution may be used as a liniment. (See *Am. Journ. of Pharm.*, xxvii. 73.) The salt has also been administered successfully by the hypodermic method (see *Treatise on Therapeutics and Pharmacology*, by the author, 3d ed., i. 273); and through the respiratory passages by means of the atomizer. In a case of obstinate intermittent, in which the stomach refused to receive the medicine, Dr. Bugeon effected a speedy and permanent cure by administering in the latter method daily, for three or four days, about seven and a half grains of the sulphate dissolved in two ounces of water. (*Journ. de Pharm. et de Chim.*, Juillet, 1867, p. 68.)

Solutions of sulphate of quinia have been advantageously employed as local applications to indolent ulcers, and chronic mucous inflammations. (Wedderburn and Fearn, *New Orleans Med. and Surg. Journ.*, iii. 161 and 341.)

Off. Prep. Ferri et Quiniæ Citras; Pilula Quiniæ, *Br.;* Pilulæ Quiniæ Sulphatis, *U. S.;* Quiniæ Valerianas, *U. S.;* Tinctura Quiniæ, *Br;* Vinum Quiniæ, *Br.* W.

QUINIÆ VALERIANAS. *U. S.* *Valerianate of Quinia.*

"Take of Valerianic Acid *half a troyounce;* Sulphate of Quinia *two troyounces;* Diluted Sulphuric Acid, Water of Ammonia, Water, each, *a sufficient quantity.* Dissolve the Sulphate of Quinia in a pint of Water, with the aid of Diluted Sulphuric Acid; then add Water of Ammonia in slight excess, and wash the precipitated quinia with water until freed from sulphate of ammonia. Dissolve the Valerianic Acid in five pints of Water, heated to 180°, add the quinia to the solution, and, when it is dissolved, set the whole aside for several days to crystallize. Decant the mother-water from the crystals, dry them on bibulous paper, and keep them in a well-stopped bottle. By evaporating the mother-water at a temperature not exceeding 120°, more crystals may be obtained." *U. S.*

In this process quinia is first obtained by decomposing sulphate of quinia, by means of ammonia, and then combined directly with valerianic acid, to form valerianate of quinia, which crystallizes from the solution when it cools, because much less soluble in cold than in hot water. By the late Dublin formula, which, with the salt itself, has been omitted in the British Pharmacopœia, the valerianate was obtained by double decomposition between muriate of quinia and valerianate of soda, resulting in the production of chloride of sodium, which remained in solution, and valerianate of quinia, which crystallized.

Valerianate of quinia is a colourless salt, crystallizing in rhomboidal plates. It has a bitter taste, and the strong, adhesive odour of valerianic acid, which is very repulsive, and quite distinct from that of oil of valerian. It is soluble in 110 parts of cold and 40 parts of boiling water, and is deposited from its warm solution in fine crystals on cooling. It is dissolved by 6 parts of cold, and by an equal weight of boiling alcohol, and is soluble also in ether. In boiling water it melts into oily globules, and undergoes decomposition, with the escape of valerianic acid; and hence the direction in the formula not to exceed 120° in evaporating the mother-water. Even at common temperatures it is probably undergoing a constant, though slow loss of the acid, of which it smells so strongly. Exposed to a dry heat, it melts and gives off white vapours. It may be given in the dose of a grain or two repeated several times a day, in cases of debility attended with nervous disorder. A combination of Peruvian bark and valerian has long been known as peculiarly efficacious in hemicrania. Perhaps the valerianate of quinia may be used advantageously in the same affection. Two instances are on record of effects similar to those of belladonna, having resulted from the exhibition of valerianate of quinia; and, on chemical examination of a portion of the same salt, the presence of atropia was detected. Nothing was known of the origin of this impurity; but it was supposed to have been purely accidental. (*Journ. de Pharm.*, 4e sér., i. 269.) W.

RESINÆ.

Resins.

The *Resinæ* or *Resins* of the U. S. Pharmacopœia constitute a peculiar class of preparations, made by exhausting the substances from which they are obtained by alcohol, and then precipitating the resinous matter from the tincture, by the addition of water, which abstracts the alcohol by its stronger affinity. It is obvious that the resins thus prepared are different substances from the alcoholic extracts, which contain all the ingredients of the medicine which alcohol is able to take from it. This set of substances has been much employed by the practitioners styling themselves "eclectics;" but with great want of discrimination. They have applied names to these resinous precipitates, which, in their proper scientific use, are employed to designate neuter proximate principles of plants, generally representing more or less completely the effects of the plants respectively on the system; as we say *colombin, quassin, santonin*, &c., themselves proper proximate principles, and representing the virtues, in part at least, of columbo, quassia, santonica, &c. from which they are

obtained, and from which they derive their names. By applying similar names to their precipitated resins, such as podophylline, iridine, cimicifugine, &c., to the impure resins obtained by precipitating the tinctures of podophyllum, iris versicolor, cimicifuga, &c., they justify the suspicion that they ignorantly believe them to be in fact the active principles of these medicines respectively, or, knowing better themselves, they seek to impose such a conviction upon the ignorant. The fact is that the substances thus obtained, and thus named, are impure resins, which may possibly be active, as in the case of the so-called podophylline, or may contain more or less of the active principles mixed with them, but are not entitled to names which imply that they are distinct proximate principles themselves. W.

RESINA JALAPÆ. *U. S.* Jalapæ Resina. *Br.* *Resin of Jalap.*

"Take of Jalap, in fine powder, *sixteen troyounces;* Alcohol, Water, each, *a sufficient quantity.* Moisten the Jalap with four fluidounces of Alcohol, pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it until four pints have passed, or until the filtered liquid ceases to occasion turbidness when dropped into water. Reduce the tincture to half a pint by distilling off the alcohol, mix the residue with four pints of water, separate the precipitate formed, wash it thoroughly with Water, and dry it with a gentle heat." *U. S.*

"Take of Jalap, in coarse powder, *eight ounces* [avoirdupois]; Rectified Spirit, Distilled Water, each, *a sufficiency.* Digest the Jalap with sixteen fluidounces of the Spirit in a covered vessel, at a gentle heat, for twenty-four hours; then transfer to a percolator, and, when the tincture ceases to pass, continue the percolation with successive portions of Spirit until it ceases to dissolve anything more. Add to the tincture four fluidounces of the Water, and distil off the Spirit by a water-bath. Remove the residue while hot to an open dish, and allow it to become cold. Pour off the supernatant fluid from the resin, wash this two or three times with hot water, and dry it on a porcelain plate by the heat of a stove or water-bath." *Br.*

The two processes probably do not differ very materially in the result; though, if jalap yield anything to alcohol that is insoluble in water besides resin, it will be necessarily found in the British preparation, while that of the U. S. Pharmacopœia consists of resin almost exclusively. The difference arises from the circumstance that, in the Br. process, probably to enable the whole of the alcohol to be saved by distillation, the water for precipitation is added before the spirit is distilled off, while, in the U. S. process, it is not added until so much of the alcohol has been distilled as to leave only enough to hold the extracted matters in solution. It is obvious, therefore, that the resin of the former contains everything insoluble in water that the alcohol had extracted; while that of the latter contains nothing which water was unable to precipitate from the half pint of concentrated tincture. The U. S. resin is probably, therefore, a purer product than the British.

The U. S. resin, though tolerably pure, and quite sufficiently so for practical purposes, is still coloured. To obtain it colourless, if this be desired, the powdered jalap should be mixed, before percolation, with an equal quantity of finely powdered animal charcoal, and, previously to the introduction of this mixture into the percolator, half the quantity of animal charcoal, similarly powdered, should be packed in the bottom of the instrument. The colouring matter is thus left behind; and the resulting tincture, treated as directed in the process, yields the resin as white as starch.

Resin of jalap consists of two portions, one of which is hard and insoluble in ether, the other is soft and soluble in that menstruum; the former constituting about 70 per cent. It is insoluble in oil of turpentine. (*Squire.*) For an account of its chemical properties the reader is referred to the article on jalap, in *Part* I. It was at one time supposed that the purgative properties of the resin resided chiefly if not exclusively in the hard resin; but experiments by Mr. John C. Long appear to prove that the soft is equally energetic. (*Am. Journ of Pharm.*, Nov. 1861, p. 489.)

Guaiac, rosin, and other resinous substances are said to be sometimes fraudulently added to the resin of jalap. Guaiac may be detected by the green colour it produces, when a few drops of solution of chloride of soda or of lime are added to an alcoholic solution of the suspected resin. (*Journ. de Pharm.*, 3e sér., x. 357.) Aloes, suspected by the bitterness of the resin, was detected in a specimen by M. Daenen, of Brussels, who obtained carbozotic acid from it by acting on it with nitric acid. (*Am. Journ. of Pharm.*, July, 1866, p. 375.) According to G. A. Kaiser, jalap resin may be distinguished from all other resins by being gradually dissolved by concentrated sulphuric acid, and depositing, after some hours, a brown soft viscid matter. (*Chem. Gaz.*, Jan. 1845; from *Liebig's Annalen.*) A better test is probably that proposed by A. Buchner. When pure jalap resin is dissolved in an alkaline solution, it is not precipitated by the addition of sulphuric or muriatic acid, having been converted, through the agency of the alkali, into an acid soluble in water. All the adulterating resins yield precipitates under the same circumstances. The resins of scammony and of fusiform jalap act in this respect like the true jalap resin, but are distinguishable by being wholly soluble in ether, which jalap resin is not. (*Neues Repert. für Pharm.*, no. 1, 1854.)

It is now generally believed that the resin of jalap is its sole purgative principle, the gummy extractive being either simply diuretic or wholly inert. Nevertheless, the extract of jalap probably better represents the whole virtues of the root, its specially hydragogue as well as simply purgative property; or at least contains the resin so involved with other ingredients, as in some measure to qualify its irritant and griping properties, and thus favourably modify its cathartic action. To obviate the occasional harshness of the resin, it has been advised to triturate it with loaf-sugar, sulphate of potassa, almond emulsion, or other substance calculated to separate its particles. It may be conveniently made into pill with mucilage or alcohol. (Hasselby, *Pharm. Journ.*, 2d ser., vii. 231.) The dose is from two to five grains. W.

RESINA PODOPHYLLI. *U.S.* Podophylli Resina. *Br.* *Resin of May-apple. Resin of Podophyllum.*

"Take of May-apple, in fine powder, *sixteen troyounces;* Alcohol, Water, each, *a sufficient quantity.* Moisten the May-apple with four fluidounces of Alcohol, pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it until four pints have passed, or until the filtered liquid ceases to occasion turbidness when dropped into water. Reduce the tincture to half a pint by distilling off the alcohol, mix the residue with four pints of Water, separate the precipitate formed, wash it thoroughly with water, and dry it with a gentle heat." *U. S.*

"Take of Podophyllum Root, in coarse powder, *one pound* [avoirdupois]; Rectified Spirit, *three pints*, or *a sufficiency;* Distilled Water, Hydrochloric Acid, each, *a sufficiency.* Exhaust the Podophyllum with the Spirit by percolation; place the tincture in a still, and draw off the greater part of the spirit. Acidulate the Water with one twenty-fourth of its bulk of Hydrochloric Acid, and slowly pour the liquid which remains after the distillation of the tincture into three times its volume of the acidulated water, constantly stirring. Allow the mixture to stand for twenty-four hours to deposit the resin. Wash the resin on a filter with Distilled Water, and dry it in a stove." *Br.*

There is a considerable difference between the preparations resulting from these two processes. The U. S. preparation is obtained simply by precipitating a concentrated tincture of the root by water, and consists mainly of the peculiar resin of podophyllum; the British, by precipitating with water acidulated by muriatic acid, whereby berberina, an alkaloid recently found to exist in podophyllum, is thrown down in the state of an insoluble muriate. As berberina exists in the may-apple, it is so combined as to be soluble both in alcohol and water, and is therefore contained in the concentrated tincture. But, having the remarkable property of forming an insoluble salt with muriatic acid, it is

thrown down along with the resin; so that the resulting preparation is a mixture of the proper resin of podophyllum with this salt. Hence the British resin is of a yellow colour, given to it by the muriate of berberina, while the U. S. resin is drab coloured. It follows that the British resin is a more exact representation of the virtues of the root than ours, while the latter is perhaps preferable simply as a purgative. Mr. Maisch has found some berberina in the resin precipitated by water from the concentrated tincture, which is removed by washing with hot water, and probably also by the thorough washing with cold water directed by the Pharmacopœia. (*Am. Journ. of Pharm.*, July, 1863, p. 303.) The percentage of resin obtained from the root, as given by different operators, varies from 3·12 to 5·25 per cent.*

Resin of podophyllum has a light-brown colour, an acrid bitter taste, and a slight odour of the root. It consists of two resins, one soluble both in ether and alcohol, the other in alcohol only. The resin extracted by ether constitutes, according to Mr. John W. Cadbury, 75 per cent. of the whole (*Am. Journ. of Pharm.*, July, 1858, p. 301), according to Mr. Harvey Allen, 80 per cent. (*Ibid.*, May, 1859, p. 206.) The officinal resin is soluble in alkaline solutions, from which it is precipitated by acids, in this respect differing strikingly from the resins of jalap and scammony. It is insoluble in oil of turpentine. The name of *podophylline*, given to it by the practitioners calling themselves eclectics, who have long been in the habit of using this resin, is inappropriate, and should be abandoned.

Resin of podophyllum is a powerful cathartic, occasionally producing some griping and nausea, but capable of being favourably modified by combination, and of being very usefully employed in connection with other cathartics, to give them increased energy. It is supposed by some to be specially cholagogue; but though, like all other active cathartics, it may occasionally produce bilious stools by emptying the gall-bladder, there is no sufficient proof that it increases especially the secretory function of the liver. There has been much difference of opinion as to the relative activity of the two resins composing it, some main-

* Dr. E. R. Squibb has recently published some interesting results in relation to the preparation of this resin, obtained from a series of laborious experiments, which are well worth the attention of those who may be engaged in the revision of our Pharmacopœia. The following is a condensed statement of his conclusions, and of his practical recommendations based upon them.

Dr. Squibb objects to the U. S. formula that muriatic acid is omitted in the precipitation, that a great excess of alcohol is directed, and that details of great importance to the production of a good preparation are wanting. The Br. process he considers even more objectionable, from an excessive use of the acid, the employment of coarse powder, the waste of spirit, the drying in a stove, and the same want of details. His objections are based upon experimental observations. These satisfied him that exhaustion, with a coarse powder, was always difficult and generally imperfect, and the finer the powder the better in these respects. They also proved that the resin precipitated without muriatic acid could not be separated without heat, which changes the physical properties of the resin, so that it could not be recognized; while too much acid causes the precipitate to be granular, heavy, moist, dark, and of diminished quantity; and the general result was in favour of an addition of not less than ten, nor more than forty, minims to a pint of water. Other conclusions were that three pints of the acidulated water were sufficient for 7680 grains of the powder, and that the product, if dried at a heat much above 90° F., is liable to become hard and discoloured, but below that degree uniformly remains light and friable, and light-coloured. But perhaps the most important results were those in relation to the quantity of alcohol requisite in percolation. Having determined that the resin was the only purgative principle, the extractive matter being quite inert; and having also ascertained that, with the continuance of the percolation, the proportion of the resin to the extractive rapidly diminishes, he inferred that the alcohol employed towards the close of the percolation yields nothing equivalent to the cost of the menstruum and the trouble of extraction; so that all the alcohol employed in the U. S. process, in the percolation, beyond the first pint, may be considered as wasted. Upon these principles Dr. Squibb prepared a formula, which he recommends, for the preparation of the resin. For an account of this process, we must content ourselves with referring to the *American Journal of Pharmacy* (January, 1868, p. 7), as we have not space for its details. It is sufficient to say here that Dr. Squibb applies in this process the principles of repercolation which he has himself developed. (*Note to the thirteenth edition.*)

taining that both are active, others that the activity resides mainly, if not exclusively, in the resin soluble in ether. It is difficult to resist the evidence of the experiments of Mr. Cadbury, who states in the paper above referred to that, while half a grain of the ethereal resin acted energetically, and a cathartic effect was produced by even one-fourth of a grain, the portion insoluble in that menstruum was given in the dose of one grain without any effect whatever. The dose of the officinal resin is from one-fourth of a grain to a grain. It should generally be given in combination. A small proportion of extract of belladonna or hyoscyamus is said much to mitigate its irritant action. W.

RESINA SCAMMONII. *U. S.* Scammoniæ Resina. *Br.* *Resin of Scammony.*

"Take of Scammony, in fine powder, *six troyounces;* Alcohol, Water, each, *a sufficient quantity.* Digest the Scammony with successive portions of boiling Alcohol until exhausted. Mix the tinctures, and reduce the mixture to a syrupy consistence by distilling off the alcohol. Then add the residue to a pint of Water, separate the precipitate formed, wash it thoroughly with Water, and dry it with a gentle heat." *U. S.*

"Take of Scammony Root, in coarse powder, *eight ounces* [avoirdupois]; Rectified Spirit, Distilled Water, each, *a sufficiency.* Digest the Scammony Root with sixteen fluidounces of the Spirit in a covered vessel, at a gentle heat, for twenty-four hours; then transfer to a percolator, and, when the tincture ceases to pass, add more Spirit and let it percolate slowly until the root is exhausted. Add to the tincture four fluidounces of the Water, and distil off the Spirit by a water-bath. Remove the residue while hot to an open dish, and allow it to become cold. Pour off the supernatant fluid from the resin, wash this several times with hot water, and dry it on a porcelain plate with the heat of a stove or water-bath. It may also be prepared in a similar way from Scammony." *Br.*

The U. S. and British resins, though procured, the former from the gum-resin, the latter from the root of the plant, are nearly identical in their effects. The advantage of the preparation is that the resin is obtained free from the inert matters with which it is so often associated in the scammony of commerce. When pure virgin scammony can be procured any preparation is unnecessary. Obtained according to the U. S. process, the resin is of a dirty greenish-brown colour, with a feeble odour and taste of scammony, and is very soluble in ether, alcohol, and boiling proof spirit. When purified with animal charcoal it has a pale brownish-yellow colour, and is without odour or taste; but retains its purgative property. The Br. resin is in brownish translucent pieces, with a resinous fracture, and of a sweetish, fragrant odour derived from the root, and wholly different from that of scammony.

The resin of scammony is liable to adulteration. Jalap resin may be detected by its partial insolubility in rectified ether, which dissolves that of scammony in all proportions. Sulphuric acid is the best test of common rosin or colophony, producing instantaneously with this substance an intense red colour; while in the resin of scammony it causes no immediate change. For the tests of guaiac, the reader is referred to that article in the Materia Medica. (See also *Am. Journ. of Pharm.*, xxiv. 158.) In regard to this sophistication, the Br. Pharmacopœia directs that the tincture shall not render the fresh-cut surface of a potato blue. The presence of other resins, besides those of the Convolvulaceæ, may be known by yielding precipitates when sulphuric acid is added to their alkaline solution; the resin of scammony agreeing with that of jalap in not affording a precipitate under such circumstances. Mr. Ch. Bullock has found this resin, as well as that of jalap and of podophyllum, to be insoluble in benzole, thus enabling any resin soluble in this liquid, which may be employed in their sophistication, to be readily detected. (*Am. Journ. of Pharm.*, March, 1862, p. 114.) When rubbed with unskimmed milk, the resin of scammony forms a uniform emulsion, undistinguishable from rich milk itself. This is an excellent mode of administration.

The resin should always be given either rubbed up with some mild powder, or in emulsion. The dose is from four to eight grains.

SANTONINUM.

Santonin.

SANTONINUM. *U. S.*, *Br.* *Santonin.*

"Take of Santonica, in moderately coarse powder, *forty-eight troyounces;* Lime, recently slaked and in fine powder, *eighteen troyounces;* Animal Charcoal, in fine powder, Diluted Alcohol, Acetic Acid, Alcohol, each, *a sufficient quantity.* Digest the Santonica and Lime with twelve pints of Diluted Alcohol for twenty-four hours, and express. Repeat the digestion and expression twice with the residue, using the same quantity of Diluted Alcohol. Mix the tinctures, and reduce the mixture to eight pints by distilling off the alcohol. Then, having filtered, and evaporated to one-half, gradually add Acetic Acid until in slight excess, stirring during the addition, and set the whole aside for forty-eight hours. Place the resulting crystalline mass upon a funnel loosely stopped, wash it with water, and dry it. Next, boil the dry residue with ten times its weight of Alcohol, and, having digested the tincture for several hours with Animal Charcoal, filter it while hot, and add sufficient hot Alcohol, through the filter, to wash the Charcoal thoroughly; then set it aside in a dark place to crystallize. Lastly, dry the crystals on bibulous paper in the dark, and keep them in a well-stopped bottle, protected from the light. By evaporating the mother-water, more crystals may be obtained." *U. S.*

"Take of Santonica, bruised, *one pound* [avoirdupois]; Slaked Lime *seven ounces* [avoird.]; Hydrochloric Acid *a sufficiency;* Solution of Ammonia *half a fluidounce;* Rectified Spirit *fourteen fluidounces;* Purified Animal Charcoal *sixty grains;* Distilled Water *a sufficiency.* Boil the Santonica with a gallon [Imperial measure] of the Water and five ounces [avoird.] of the Lime, in a copper or tinned iron vessel, for an hour, strain through a stout cloth, and express strongly. Mix the residue with half a gallon [Imp. meas.] of the Water and the rest of the Lime, boil for half an hour, strain and express as before. Mix the strained liquors, let them settle, decant the fluid from the deposit, and evaporate to the bulk of two pints and a half [Imp. meas.]. To the liquor while hot, add, with diligent stirring, the Hydrochloric Acid until the fluid has become slightly and permanently acid, and set it aside for five days that the precipitate may subside. Remove by skimming any oily matter which floats on the surface, and carefully decant the greater part of the fluid from the precipitate. Collect this on a paper filter, wash it first with cold Distilled Water till the washings pass colourless and nearly free from acid reaction, then with the Solution of Ammonia previously diluted with five fluidounces of the Water, and lastly with cold Distilled Water till the washings pass colourless. Press the filter containing the precipitate between folds of filtering paper, and dry it with a gentle heat. Scrape the dry precipitate from the filter, and mix it with the Animal Charcoal. Pour on them nine ounces of the Rectified Spirit, digest for half an hour, and boil for ten minutes. Filter while hot, wash the charcoal with an ounce of boiling Spirit, and set the filtrate aside for two days in a cool dark place to crystallise. Separate the mother-liquor from the crystals, and concentrate to obtain a further product. Collect the crystals, let them drain, redissolve them in four ounces of boiling Spirit, and let the solution crystallise as before. Lastly, dry the crystals on filtering paper in the dark, and preserve them in a bottle protected from the light." *Br.*

By the U. S. process, which was taken from Wittstein's *Pharmaceutical Chemistry* (page 563), the santonica is first exhausted by digestion with diluted alcohol, in connection with slaked lime; the latter substance being employed to

saturate the santonin, and remove colouring matter which might subsequently embarrass the proceedings. The tincture thus obtained, having been reduced by the distillation of the alcohol to little more than an aqueous solution, is filtered and treated with acetic acid, in slight excess, by which the santonin is separated from the lime which holds it in solution, and, being itself insoluble, is gradually deposited in a crystalline state. The remainder of the process is intended simply to obtain the crystals free from colouring matter, and otherwise pure.

The British process, which is that of M. Mialhe somewhat modified (*Pharm. Journ.*, June, 1864, p. 635), spares the expenditure of alcohol in the exhaustion of the santonica, by boiling it originally with water in connection with lime; and differs also from the preceding in precipitating the santonin by muriatic instead of acetic acid. The purification is effected in the same manner, except that solution of ammonia is employed in the washing, probably to remove the last trace of acid. Wormseed of Aleppo yields from 1·2 to 1·4 per cent. of santonin. (*Journ. de Pharm.*, Mars, 1864, p. 241.) It has been intimated to us that the large manufacturers of santonin, abroad, first distil off from the santonica its volatile oil, which has some commercial value in Europe; and that, so far from being injured by the operation, the process for preparing santonin is probably facilitated, in consequence of an affinity of the oil for the santonin, which may render it more difficult to obtain that principle pure.

Properties. Santonin is in colourless crystals, which have the form of flat rhombic prisms. It is inodorous, and at first nearly tasteless, but after a time produces a sense of bitterness. It is fusible by a moderate heat, and assumes the form of a crystalline mass on cooling. At a somewhat higher heat, it rises in dense, white, irritating vapours, and condenses unchanged. The air has no effect upon it, but it becomes yellow on exposure to sunlight. According to M. Sestini, the santonin is changed, through the influence of light, into formic acid, an uncrystallizable substance much more soluble in alcohol and ether than santonin itself, which he calls *photosantonic acid*, and a red resinous substance. (See *Am. Journ. of Pharm.*, Nov. 1864, p. 527.) In a subsequent account of this new substance, in which he gives further details, M. Sestini proposes to change its name to *photosantonine*, being apparently uncertain as to its acid properties. (*Chem. News*, Aug. 11, 1865, p. 61.) It is nearly insoluble in cold water, or in weak acid solutions, but is dissolved by 250 parts of boiling water, by 43 parts of cold and 3 parts of boiling alcohol, and by 75 parts of ether; and its alcoholic and ethereal solutions are extremely bitter. (*U. S.*) It is also freely soluble in chloroform. Though neuter to test paper, it unites with alkaline bases to form crystallizable and soluble salts. In its relations to polarized light, it is very strongly lævogyrate, more so than any other body previously noticed, and retains this property with acids, though losing it entirely when combined with salifiable bases. (Buignet, *Journ. de Pharm.*, Janv. 1862, p. 26.) When exposed to red heat, with access of air, it is entirely dissipated. It consists of carbon, hydrogen, and oxygen; its formula being $C_{30}H_{18}O_6$. In chemical character it appears to be analogous to the stearoptenes, or concrete principles of the volatile oils. Under the influence of sulphuric acid and heat, it was said to be resolved into glucose and a new body, for which the name of *santoniretin* has been proposed, and was consequently supposed to rank with the glucosides. (Kosmann, *Journ. de Pharm.*, Août, 1860, p. 81.) But this statement has been disproved. Though, when long boiled with sulphuric acid, it is somewhat changed, and assumes a resinous appearance, yet the only result is the abstraction of water, and the santonin may be recovered unchanged. Not a particle of glucose can be detected. It is, therefore, not a glucoside. (Schmidt, *Ibid.*, 4e sér., iii. 394.)

Medical Properties and Uses. The effects of santonin on the system do not appear to have been very precisely determined. Without any very obvious effects on the circulation or digestive organs, it seems to produce some impression of a slightly narcotic character on the brain, and occasionally operates feebly as a diuretic. A singular effect on vision which has often been observed from santo-

nica, is probably owing to the santonin, as similar effects have been produced by that principle. To persons under the influence of santonin, it often happens that all objects appear discoloured, generally yellow, but frequently also green, and sometimes blue. At the same time the urine is tinged of a yellow or green colour; and so rapidly does the santonin pass, that the change of colour in the urine has been observed at the end of 16 minutes. (*Journ. de Pharm.*, Août, 1863, p. 161.) These effects are ascribed to a change of the santonin in the system analogous to that which takes place by its exposure to light; the yellow substance circulating with the blood, and passing out of the circulation with the urine. Santonin has been found to possess the vermifuge properties of santonica, and is probably its exclusive anthelmintic principle; as the volatile oil, to which this property was at one time ascribed, has little or no effect, being probably absorbed from the stomach before it reaches the worms in the bowels, while the santonin, being insoluble, or only becoming soluble by partial conversion into the santonate of soda when it reaches the bile in the duodenum, passes into the small intestines and poisons the worms. Besides, the volatile oil is poisonous to the system in large doses, while santonin is innocent in any quantity in which it is likely to be administered. (*Edm. Rose, of Berlin.*) A case of poisoning ascribed to santonin was found to be owing to strychnia mixed with it. (*Chem. News*, no. 230, p. 212.) Nevertheless, M. Pelikan, of St. Petersburg, has concluded from his investigations, that this substance is capable of producing powerful effects on the system in excessive doses; causing a species of paralysis with muscular rigidity, and acting in a manner analogous to atropia, and physostigmia. (*Ranking's Half-yearly Abstract*, xlvii. 93.) Santonin has also been found advantageous in amaurosis by M. Martin and M. Guépin, the latter of whom recommends it especially in cases which have succeeded acute choroiditis and iritis, with plastic exudation, after symptoms of inflammation have ceased. (*Ann. de Thérap.*, 1862, pp. 179, 183.) Dr. Z. C. McElroy, of Zanesville, Ohio, states, as the result of observation, that santonin, added to cathartic pills, materially modifies their action, increasing their activity, and obviating their griping effect. (*Med. and Surg. Reporter*, xv. 166, A.D. 1866.) Santonin may be given in doses of two or three grains twice or three times a day. Some have recommended its salts, but Rose objects to these as being soluble, and therefore not so likely to reach the worm, in consequence of absorption; and, besides, in large doses they are injurious. In amaurosis, M. Guépin uses it in the form of syrup; its solubility being, in this case, a recommendation. The syrup may be made by mixing a drachm of santonin, dissolved in a little alcohol, with eight fluid-ounces of syrup, of which two teaspoonfuls may be given for a dose. Santonin may also be given in the form of lozenge with sugar and tragacanth. A formula will be found in the *Am. Journ. of Pharm.* (vi. N. S., p. 124). M. Guyot Darencey recommends that the lozenges should be made of the santonin in crystals, unpowdered, as in this state its unpleasant taste is almost entirely avoided. (*Ibid.*, July, 1868, p. 330.) W.

SODA.

Preparations of Soda.

SODA CAUSTICA. *Br. Caustic Soda.*

"Take of Solution of Soda *two pints*. Boil down the Solution rapidly, in a silver or clean iron vessel, until there remains a fluid of oily consistence, a drop of which when removed on a warmed glass rod solidifies on cooling. Pour the fluid on a clean silver or iron plate, or into moulds, and, as soon as it has solidified, break it in pieces, and preserve it in stoppered green-glass bottles." *Br.*

The solution of Soda, being a solution of the caustic alkali, yields it on evaporation in the solid state. Metallic vessels are used in consequence of the chemical action of soda on earthenware or porcelain, and the product is directed to be kept in green-glass bottles, because these resist its action better

than those of white glass. Instead of being poured into cylindrical moulds to harden, as caustic potassa, this is allowed to solidify in mass, and is broken into irregular fragments.

A method of preparing soda directly from common salt, through the agency of lead or its oxide, has been proposed in England by Mr. S. Rowbotham. The chloride of sodium is either fused with metallic lead, or mixed with the oxide and water, and allowed to stand till decomposition takes place, the whole being kept moist with steam. The salt abandons its chlorine to the lead; and the caustic soda resulting from the oxidation of the sodium, is extracted by lixiviation. The lead is recovered for future use by exposing the chloride to oxygen with heat. (*Chem. News*, May 24, 1867, p. 266.)

As prepared by the officinal process, caustic soda is in grayish-white fragments, opaque, brittle, and extremely corrosive. It is deliquescent, very soluble in water, soluble in alcohol, and possessed of all the alkaline properties of potassa, from which it differs in imparting a yellow colour to flame, and in not giving in solution a yellow precipitate with bichloride of platinum, or a crystalline precipitate with tartaric acid in excess. When heated it melts, and at an intense heat evaporates. In composition, it is the hydrated oxide of sodium (NaO,HO), and cannot be deprived of its water by heat. Though deliquescent, like potassa, it does not like that alkali become permanently liquid, but forms a paste, which after a time effloresces. The difference in this respect between the two alkalies is owing to the circumstance that, while both are converted into carbonates by uniting with the carbonic acid of the air, potassa forms a deliquescent, and soda an efflorescent salt. It is apt to contain impurities originating from the carbonate of soda used in preparing the solution from which it is made; and the presence of these is recognised by the Br. Pharmacopœia, when it states that the aqueous solution, acidulated with nitric acid, gives a scanty white precipitate with nitrate of silver and chloride of barium, indicating the existence of a chloride and sulphate or carbonate. According to the same authority, it leaves scarcely any sediment when dissolved in water, and 40 grains require for neutralization about 900 grain-measures of the *volumetric solution of oxalic acid*. If the solution be coloured brown by sulphuretted hydrogen or hydrosulphate of ammonia, the presence of lead may be suspected, derived probably from the glass vessels in which it has been kept. It may be used externally as a caustic in the same manner as potassa, for which purpose it may be melted and cast into sticks. It has the advantage of being less deliquescent, and probably milder. It may be used also for making the solution of soda extemporaneously, for which purpose a drachm may be dissolved in three and a half fluidounces of distilled water. W.

SODÆ ARSENIAS. *Br. Arseniate of Soda.*

"Take of Arsenious Acid *ten ounces* [avoirdupois]; Nitrate of Soda *eight ounces and a half* [avoird.]; Dried Carbonate of Soda *five ounces and a half* [avoird.]; Boiling Distilled Water *thirty-five* [*fluid*]*ounces*. Reduce the dry ingredients separately to fine powder, and mix them thoroughly in a porcelain mortar. Put the mixture into a large clay crucible, and cover it with the lid. Expose to a full red heat, till all effervescence has ceased, and complete fusion has taken place. Pour out the fused salt on a clean flagstone, and as soon as it has solidified, and while it is still warm, put it into the boiling Water, stirring diligently. When the salt has dissolved, filter the solution through paper, and set it aside to crystallise. Drain the crystals, and, having dried them rapidly on filtering paper, enclose them in stoppered bottles." *Br.*

This was first made officinal by the Br. Pharmacopœia of 1864. In the process, the arsenious acid is converted into arsenic acid at the expense of the nitric acid of the nitrate of soda, and then combines with the soda of both salts, carbonic acid and nitrous fumes being given off. As the salt consists of two eqs. of base to one of acid, each eq. of arsenious acid, having been converted into arsenic acid by two eqs. of oxygen from one eq. of the nitric acid of the nitrate, combines with the separated eq. of soda of that salt, and with another eq. of soda of

the carbonate; and the three substances employed are therefore required in the proportion of their equivalents. This is almost exactly the case in the formula, the nitrate being very slightly in excess, and the carbonate about in the same proportion deficient. According to Mr. Higgins, the gases emitted in this process contain more or less arsenic; an inconvenience which may be avoided by first dissolving the arsenious acid in a solution of caustic soda, and then adding the nitrate. The calcination should be performed in a reverberatory furnace. The gases which escape up the chimney are now free from arsenic, and consist only of ammonia and nitrous vapours. (*Journ. de Pharm.*, 4e sér., ii. 177.)

Arseniate of soda is in colourless, transparent crystals, soluble in two parts of water (*Squire*), of a somewhat saline taste leaving a slight sense of acrimony, and with an alkaline reaction. Heated to 300° it melts, and loses its water of crystallization and 40·38 per cent. of its weight. "A solution of 10 grains of the residue, treated with 53 grain-measures of the *volumetric solution of soda*, continues to give a precipitate with the *volumetric solution of nitrate of silver* until 1613 grain-measures of the latter have been added." (*Br.*) In this test the soda is added in order that, by the decomposition of the nitrate of silver, one additional eq. of oxide of silver may be furnished, so as, with the two eqs. given up in exchange for the two eqs. of soda of the arseniate of soda, to make up the three eqs. necessary for the formation of the arseniate of silver ($3AgO,AsO_5$). The precipitate is arseniate of silver, and the quantity precipitated should be equivalent to 6·16 grains of arsenic acid. The aqueous solution of arseniate of soda gives white precipitates with chloride of barium, chloride of calcium, and sulphate of zinc (arseniates of baryta, lime, and zinc), and a brick-red precipitate with nitrate of silver (arseniate of silver).

Arseniate of soda is composed of two eqs. of soda 62, one eq. of basic water 9, one eq. of arsenic acid 115, and fourteen eqs. of water of crystallization 126 =312; arsenic acid being tribasic. Its formula, therefore, is $2NaO,HO,AsO_5 + 14HO$.

In medical properties this salt agrees with the other preparations of arsenic (see *Acidum Arseniosum*), and may be employed for the same purposes. It is preferred by some, under the impression that it is milder than the arsenious acid or the arsenites; and, in the same dose, it certainly contains somewhat less metallic arsenic. The dose of the crystallized salt is stated at from one-twelfth to one-third of a grain; but it is generally prescribed in the form of solution. (See *Liquor Sodæ Arseniatis.*) This may be made extemporaneously by dissolving 4 grains of the anhydrous or 6·5 grains of the crystallized salt in a fluidounce of distilled water. *Pearson's arsenical solution* is an aqueous solution of arseniate of soda, containing one grain of the salt in a fluidounce, and therefore much weaker than the officinal solution. This preparation is considerably used on the continent of Europe in the form of bath, for which it is preferred to arsenious acid or the arsenites. M. Gueneau de Mussy recommends it strongly, administered in this way, in nodose rheumatism, or rheumatic gout, using it alone in the more acute forms of the disease, and combined with carbonate of soda in the chronic. He uses from half a drachm to two or three drachms of the arseniate to each bath, beginning with the smaller quantity, and gradually increasing. (*Ann. de Thérap.*, 1865, p. 270.)

SODÆ BICARBONAS. *U.S., Br.* *Bicarbonate of Soda.*

"Take of Carbonate of Soda *a convenient quantity.* Put the Carbonate, previously broken in pieces, into a wooden box, having a horizontal partition near the bottom pierced with numerous small holes, and a cover which can be tightly fitted on. To a bottle having two tubulures, and half filled with water, adapt two tubes, the first passing from an apparatus for generating carbonic acid, through one tubulure, to a point below the surface of the water in the bottle; the second reaching from the other tubulure to an opening near the bottom of the box, be-

neath the partition. Then lute all the joints, and cause a stream of carbonic acid to pass through the water into the box until the Carbonate is fully saturated. Lastly, remove the product from the box, and, having dried it, rub it into powder. Carbonic acid may be obtained from Marble by the addition of dilute Sulphuric Acid." *U. S.*

"Take of Carbonate of Soda *two pounds* [avoirdupois]; Dried Carbonate of Soda *three pounds* [avoird.]; White Marble, in fragments, *four pounds* [avoird.]; Hydrochloric Acid *one gallon* [Imperial measure]; Water *two gallons* [Imp. meas.]; Distilled Water *a sufficiency.* Fill with the Marble a tubulated glass bottle having a few small holes drilled in the bottom, connect the tubulure tightly by a bent tube and corks with an empty two-necked bottle, and connect this with another bottle filled with the Carbonates of Soda well triturated together, and let the tube be long enough to reach the bottom of the bottle. Before fixing the cork in the bottle containing the Carbonate of Soda, partially immerse the bottle containing the Marble in the Hydrochloric Acid previously diluted with the Water and placed in any convenient vessel. When the whole apparatus is filled with carbonic acid gas, fix in tightly the cork of the bottle containing the Carbonate of Soda, and let the action go on until the gas ceases to be absorbed. Pour upon the damp salt which is formed half its weight of cold Distilled Water, and shake it occasionally during the course of half an hour, then drain the undissolved portion, and dry it by exposure to the air on filtering paper placed on porous bricks." *Br.*

The object of these processes is to unite the soda with an additional equivalent of carbonic acid, whereby it becomes converted into the bicarbonate.

The process adopted in the U. S. Pharmacopœia, since 1840, is that which has been practised for many years in the United States, and was described in 1830 by Dr. Franklin R. Smith, in the first volume of the Journal of the Philadelphia College of Pharmacy. This process is attributed to Dr. Smith by Soubeiran, who characterizes it as the best that can be employed. It was adopted in the French Codex on its revision of 1837. A stream of carbonic acid, freed from any accompanying impurity by passing through water in the intervening bottle, is conducted into a suitable vessel, containing the crystallized carbonate placed on a diaphragm, pierced with numerous holes. As the bicarbonate combines with much less water of crystallization than is contained in the carbonate, it follows that, during the progress of the saturation of the carbonate, a considerable quantity of water is liberated. This water would finally dissolve a portion of the bicarbonate formed, were it not for the pierced diaphragm, through which it is allowed to drain off holding in solution a part of the carbonate. When the saturation is completed, the pieces of crystals, still supported on the diaphragm, are found to have retained their original form, but to have become opaque and of a porous texture. The necessary carbonic acid for forming the bicarbonate may be economically obtained from other processes in which this acid is evolved; as, for example, from the process for making tartaric acid, in which tartrate of lime is formed from cream of tartar by the addition of carbonate of lime.

The British process is that of Berzelius. In the U. S. process, the excess of water over the quantity necessary for the bicarbonate is allowed to drain off; but it holds a certain portion of carbonate in solution, which thus escapes the action of the carbonic acid. To avoid this result it is only necessary to prepare a carbonate containing just sufficient water of crystallization to accommodate the bicarbonate; and the process recommended by Berzelius accomplishes that purpose. Thus, the salt which he prepares to be submitted to the carbonic acid, is an intimate mixture, in fine powder, of four parts of effloresced carbonate, with one of the crystallized salt. The proportion adopted by the Br. Pharmacopœia is different, namely, three parts of the dried carbonate to two of the crystallized carbonate; and is such as to afford an excess of water over that required to constitute the bicarbonate. Hence this process furnishes a damp salt, which is first washed with a small portion of water to free it from any remaining carbonate, and then dried in the air without heat. The apparatus employed for ob-

taining the carbonic acid is precisely the self-regulating generator, devised by Dr. Hare on the principle of Gay-Lussac's. The empty bottle, placed between the generating apparatus and that containing the salt, is intended, as in the U. S. process, to detain any impurity which may be carried over with the stream of carbonic acid.

Artus has given a process for obtaining bicarbonate of soda, similar to that of Wöhler for forming the corresponding salt of potassa. (See *Potassæ Bicarbonas.*) In this process, the effloresced carbonate, mixed with half its weight of freshly ignited and finely powdered charcoal, is saturated by a stream of carbonic acid, derived from the fermentation of sugar. The presence of the charcoal greatly promotes the absorption. (*Pharm. Cent. Blatt*, 1843, p. 254.)

We are informed that much bicarbonate of soda is now prepared in breweries, in the same manner as bicarbonate of potassa or sal aëratus, by placing the carbonate in suitable vessels over the fermenting beer in the vats, so as to be constantly immersed in an atmosphere of carbonic acid. It is sold under the same name as the analogous salt of potassa; but is sometimes distinguished as the *soda sal aëratus.*

Properties, &c. As obtained by the U. S. formula, bicarbonate of soda is in opaque, porous masses, made up of numerous, aggregated crystalline grains, having a snow-white colour. For the convenience of the apothecary these masses are reduced to powder. As procured by the Br. process, it is in small, white, opaque, irregular scales. Bicarbonate of soda is permanent in the air, and slightly alkaline to the taste and to turmeric paper. It is soluble in thirteen parts of cold water. When the solution is exposed to heat, the salt gradually parts with carbonic acid, and, at the temperature of 212°, is converted into sesquicarbonate. At a red heat, the water of crystallization and the second equivalent of carbonic acid, amounting together to 37 per cent., are expelled, and the anhydrous carbonate is left. One eq., or 84·3 parts of the crystallized bicarbonate, should lose, on complete decomposition by dilute sulphuric acid, two eqs. or 44 parts of carbonic acid, equal to 52·1 per cent. The salt is seldom so perfect as to satisfy this test; as good commercial samples generally contain from 2 to 3 per cent. of carbonate. "Twenty grains neutralise 16·7 grains of citric acid, or 17·8 grains of tartaric acid. Eighty-four grains, exposed to a red heat, leave 53 of an alkaline residue, which require for neutralisation 1000 grain-measures of the *volumetric solution of oxalic acid.*" *Br.* This is almost the precise proportion of carbonate of soda which the bicarbonate should yield when deprived of its water and one eq. of carbonic acid. The presence of carbonate may be known by a decided alkaline taste and reaction, by a cold solution of the salt yielding a precipitate with sulphate of magnesia, and by a solution in 40 parts of water, affording, without agitation, an orange-coloured or reddish-brown precipitate with corrosive sublimate. The pure bicarbonate is not precipitated by bichloride of platinum, nor, when treated with nitric acid in excess, by chloride of barium or nitrate of silver. The non-action of these tests shows the absence of salts of potassa, and of sulphates and chlorides. The incompatibles of this salt are the same as those elsewhere mentioned of the carbonate, except sulphate of magnesia in the cold, which decomposes the carbonate, but not the bicarbonate.

Composition. Bicarbonate of soda, when perfect, consists of two eqs. of carbonic acid 44, one of soda 31·3, and one of water 9 = 84·3. The London College formerly prepared this salt by a faulty process, and gave it the name of sesquicarbonate. In its Pharmacopœia of 1851, it placed the salt, under the correct name of bicarbonate, in the catalogue of Materia Medica; where, perhaps, it would properly stand, as it is now prepared in great perfection on a large scale.

Medical Properties. This salt has the general medical properties of the carbonate; but, from its mild taste and less irritating qualities, proves more acceptable to the palate and stomach. It is often resorted to in calculous cases, characterized by excess of uric acid. The continued use of the carbonate, in these cases, is liable to induce phosphatic deposit, after the removal of the uric

acid. According to D'Arcet, who made the observation at the springs of Vichy this objection does not apply to the bicarbonate, especially when taken in carbonic acid water; for this salt, by its superabundant acid, has the power of maintaining the phosphates in solution, even after the alkali has caused the uric acid to disappear. The same remark is applicable to the bicarbonate of potassa. Bicarbonate of soda has been given in infantile croup, with apparent advantage in promoting the expulsion of the false membrane, in the dose of a grain every five minutes, dissolved in milk and water. Dr. Lemaire has proposed it as an antiphlogistic remedy in the treatment of pneumonia, membranous angina, and croup, supposing it to act on the principle of removing from the blood the excess of fibrin, which exists in that liquid in inflammation. Its utility in membranous angina has been confirmed by M. Marchal (de Calvi). According to M. Jeannel, the use of bicarbonate of soda lessens the sugar in the urine of diabetic patients. The dose for an adult is from ten grains to a drachm, and is taken most conveniently in a glass of carbonic acid water. When given in angina, fifteen grains may be administered every half hour in a tablespoonful of water. This salt is principally consumed in making soda and Seidlitz powders (See *page* 1363.) It is sometimes made into lozenges. (See *Trochisci Sodæ Bicarbonatis.*)

Pharm. Uses. In the preparation of Aqua Acidi Carbonici, *U. S.*

SODÆ CARBONAS EXSICCATA. *U. S., Br. Dried Carbonate of Soda.*

"Take of Carbonate of Soda *a convenient quantity.* Expose it to heat in an iron vessel, until it is thoroughly dried, stirring constantly with an iron spatula; then rub it into powder." *U. S.*

"Take of Carbonate of Soda *eight ounces.* Expose the Carbonate of Soda in a porcelain capsule to a rather strong sand heat, until the liquid which first forms is converted into a dry cake, and, having rubbed this to powder, enclose it in a stoppered bottle." *Br.*

Carbonate of soda contains ten equivalents of water of crystallization, and, when heated, readily undergoes the watery fusion. Upon continuing the heat, the water is dried off, and a white porous mass remains, which is easily reduced to powder. Dried carbonate of soda is in the form of a white powder, and differs in nothing from the crystallized, except in being devoid of water of crystallization. (See *Sodæ Carbonas.*) When decomposed by dilute sulphuric acid, it evolves 40·7 per cent. of carbonic acid. (*Lond. Pharm.*)

Medical Properties and Uses. This preparation was introduced into practice by Dr. Beddoes, who extolled its virtues in calculous complaints. It is applicable to the cure of such affections, only when dependent on a morbid secretion of uric acid. Its advantage over the common carbonate is that it admits of being made into pills, in consequence of being in the dried state. As the water of crystallization forms more than half of the carbonate, the dose of the dried salt must be reduced in proportion. From five to fifteen grains may be given three times a day, in the form of pill prepared with soap and aromatics. For the medical properties of this salt, see *Sodæ Carbonas.*

Off. Prep. Sodæ Arsenias, *Br.;* Sodæ Bicarbonas, *Br.* B.

SODÆ CITRO-TARTRAS EFFERVESCENS. *Br. Effervescent Citro-tartrate of Soda.*

"Take of Bicarbonate of Soda, in powder, *seventeen ounces;* Tartaric Acid, in powder, *eight ounces;* Citric Acid, in powder, *six ounces.* Mix the powders thoroughly, place them in a dish or pan of suitable form, heated to between 200° and 220°, and when the particles of the powder begin to aggregate, stir them assiduously until they assume a granular form; then, by means of suitable sieves, separate the granules of suitable and most convenient size, and preserve the preparation in well-closed bottles." *Br.*

The object of bringing this preparation into a granular form is, we presume, to oppose the force of cohesion to that of chemical affinity, which strongly disposes to reaction between the ingredients. When dissolved in water they undergo this reaction vigorously; the two acids combining with the soda of the bicarbonate to produce tartrate and citrate of soda, and the carbonic acid escaping with brisk effervescence. It is in this form that the preparation is intended to be used. The salts combine laxative with refrigerant properties, which adapt them to the febrile state, while the carbonic acid renders them acceptable to the stomach, and will often check nausea and vomiting when existing. The dose is one or two drachms, which may be taken in a small wineglassful or more of water, and repeated occasionally as required.

W.

SODÆ PHOSPHAS. *U.S., Br. Phosphate of Soda. Medicinal Tribasic Phosphate of Soda.*

"Take of Bone, calcined to whiteness and in fine powder, *one hundred and twenty troyounces;* Sulphuric Acid *seventy-two troyounces;* Carbonate of Soda, Water, each, *a sufficient quantity.* Mix the powder with the Sulphuric Acid in an earthen vessel; then add eight pints of Water, and, having stirred the mixture thoroughly, digest for three days, occasionally adding a little Water to replace that which is lost by evaporation, and frequently stirring the mixture. At the expiration of that time, pour in eight pints of boiling Water, and strain through muslin, gradually adding more boiling Water until the liquid passes nearly tasteless. Set by the strained liquor that the dregs may subside, and, having poured off the clear solution, boil it down to eight pints. To the concentrated liquid, poured off from the newly formed dregs and heated in an iron vessel, add by degrees Carbonate of Soda, previously dissolved in hot Water, until effervescence ceases, and the phosphoric acid is completely saturated; then filter the liquid, and set it aside to crystallize. Having removed the crystals, add, if necessary, a small quantity of Carbonate of Soda to the liquid, so as to render it slightly alkaline; then alternately evaporate and crystallize, so long as crystals are produced. Lastly, keep the crystals in a well-stopped bottle." *U. S.*

"Take of Bone Ash, in powder, *ten pounds* [avoirdupois]; Sulphuric Acid *fifty-six fluidounces;* Distilled Water *four gallons and a half* [Imperial measure], or *a sufficiency;* Carbonate of Soda *sixteen pounds* [avoird.], or *a sufficiency.* Place the Bone Ash in a capacious earthenware or leaden vessel, pour on the Sulphuric Acid, and stir with a glass rod until the whole powder is thoroughly moistened. After twenty-four hours, add gradually and with constant stirring a gallon [Imp. meas.] of the Water; digest for forty-eight hours, adding Distilled Water from time to time to replace what has evaporated. Add another gallon [Imp. meas.] of the Water, stirring diligently, digest for an hour, filter through calico, and wash what remains on the filter with successive portions of Distilled Water, till it has almost ceased to have an acid reaction. Concentrate the filtrate to a gallon, let it rest for twenty-four hours, and filter again. Heat the filtrate to near the boiling point, add the Carbonate of Soda previously dissolved in two gallons [Imp. meas.] of the Water, till it ceases to form a precipitate, and the fluid has acquired a feeble alkaline reaction. Filter through calico, evaporate the clear liquor till a film forms on the surface, and set it aside to crystallise. More crystals will be obtained by evaporating the mother-liquor, a little Carbonate of Soda being added if necessary to maintain its alkalinity. Dry the crystals rapidly, and without heat, on filtering paper placed on porous bricks, and preserve them in stoppered bottles." *Br.*

The incombustible part of bones is obtained by burning them to whiteness, and consists of a peculiar phosphate of lime, called bone-phosphate, associated with some carbonate of lime, &c. (See *Os.*) When this is mixed with sulphuric acid, the carbonate of lime is entirely decomposed, giving rise to effervescence. The phosphate of lime undergoes partial decomposition; the greater part of the lime, being detached, precipitates as sulphate of lime, while the phosphoric acid, set free, combines with the undecomposed portion of the phosphate, and remains

in solution as a superphosphate of lime, holding dissolved a small portion of the sulphate of lime. In order to separate the superphosphate from the precipitated mass of sulphate of lime, boiling water is added to the mixture, the whole is strained, and the sulphate washed as long as superphosphate is removed, which is known by the water passing through in an acid state. The different liquids which have passed the strainer, consisting of the solution of superphosphate of lime, are mixed and allowed to stand; and by cooling a portion of sulphate of lime is deposited, which is got rid of by decantation. The bulk of the liquid is now reduced by evaporation, and, in consequence of the diminution of the water, a fresh portion of sulphate of lime is deposited, which is separated by subsidence and decantation as before. The superphosphate of lime solution, being heated, is now saturated by means of a hot solution of carbonate of soda. The carbonic acid is extricated with effervescence, and the alkali, combining with the *excess* of acid of the superphosphate, generates one variety of the tribasic phosphate of soda; while the superphosphate of lime, by the loss of its excess of acid, becomes the neutral phosphate and precipitates. The phosphate of lime is separated by a new filtration; and the filtered liquor, which is a solution of phosphate of soda, is evaporated so as to crystallize.

In the U. S process, the calcined bone is to the acid as 10 to 6; in the Br. process as 10 to 6½ nearly. The proportion recommended by Berzelius is as 10 to 6·66. The acid, in the officinal processes, is added to the calcined bone in the concentrated state, and afterwards diluted with more or less water. In the process given by Berzelius it is first diluted with twelve times its weight of water. All the writers state that phosphate of soda crystallizes more readily by allowing its solution to be slightly alkaline; and a remarkable fact is, that a neutral solution, when it crystallizes, leaves a supernatant liquid which is slightly acid and uncrystallizable. Hence it is necessary, after getting each successive crop of crystals, to render the mother-water neutral or slightly alkaline, before it will furnish an additional quantity.

M. Funcke, a German chemist, has given the following cheap and expeditious method for obtaining phosphate of soda. To the powdered calcined bone, diffused in water, sufficient dilute sulphuric acid is added to decompose all the carbonate of lime which it contains. When the effervescence ceases, the matter is treated with nitric acid, which dissolves the phosphate of lime, and leaves the sulphate. The nitric solution of the phosphate is then treated with sulphate of soda, equal in quantity to the bone employed; and after the reaction is completed, the nitric acid is recovered by distillation. In consequence of a double decomposition, sulphate of lime and phosphate of soda are formed, the latter of which is separated by water, and crystallized in the usual manner.

Properties, &c. The medicinal phosphate of soda is in large colourless crystals, which have the shape of oblique rhombic prisms. They are transparent at first, but speedily effloresce and become opaque when exposed to the air. It possesses a pure saline taste, resembling that of common salt. With tests it displays an alkaline reaction. It dissolves in four parts of cold, and in two of boiling water, but is insoluble in alcohol. Before the blowpipe it first undergoes the aqueous fusion, and afterwards, at a red heat, melts into a globule of limpid glass, which becomes opaque on cooling. It is not liable to adulteration, but sometimes contains carbonate of soda, from this salt having been added in excess in its preparation; in which case it will effervesce with acids. If it contain sulphate of soda, or any other soluble sulphate, the precipitate caused by chloride of barium will be a mixture of sulphate and phosphate of baryta, and will not be totally soluble in nitric acid. Chloride of barium will detect carbonate of soda also, by producing a precipitate (carbonate of baryta), soluble with effervescence in nitric acid. If a chloride be present, the *yellow* precipitate caused by nitrate of silver will be a mixed one of chloride and phosphate of silver, not entirely soluble in the same acid. The salt is incompatible with soluble salts of lime, with which it gives a precipitate of phosphate of lime, and with neutral metallic solutions. It is found in several of the animal secretions, particularly the urine.

The medicinal phosphate of soda is one of the three tribasic phosphates of soda, characterized by having its three bases, made up of two eqs. of soda and one of water. When crystallized, it consists of two eqs. of soda 62·6, one of basic water 9, one of phosphoric acid 72, and twenty-four of water of crystallization 216 = 359·6. Its formula is, therefore, $2NaO,HO,PO_5+24HO$. When gently heated it loses its water of crystallization; and at a red heat its basic water is driven off, and the salt is converted into *pyrophosphate of soda*, or that variety of *bibasic phosphate* which has the formula $2NaO,PO_5$. This bibasic phosphate is characterized by giving a *white* precipitate with nitrate of silver. When the medicinal salt is thus dried and ignited, it loses 63 per cent. of its weight; and the residue, dissolved in water, gives with chloride of barium a precipitate almost entirely soluble in dilute nitric acid. (*Br.*)

Medical Properties and Uses. Phosphate of soda was introduced into practice, about the year 1800, by the late Dr. Pearson, of London. It is a mild purgative, and, from its pure saline taste, is well adapted to the cases of children, and of persons of delicate stomach. The dose is from one to two ounces, and is best given in gruel or weak broth, to which it gives a taste, as if seasoned with common salt. B.

Until recently, phosphate of soda was not thought to possess any other medicinal virtues than those of a cathartic. Of late, however, it has been considerably used, generally in connection with other phosphates, and in small doses, to meet any real or supposed deficiency of phosphorus or of phosphates in the system, and for this purpose it is well adapted by its ready solubility. But from the observations of Dr. Wm. Stephenson, of Edinburgh, recently published, there is reason to believe that this salt, in small doses, especially in children, exercises an extraordinary influence upon the hepatic secretion. In infantile cases, with white or green stools, with diarrhœa, and sometimes with jaundice, Dr. Stephenson has found these evidences of deficient or disordered bile to yield quickly to small doses of phosphate of soda; the passages assuming their healthy yellow colour, and the attendant disease generally disappearing. The dose is from three or four to ten grains for children, according to the age, and is best administered with their food, especially milk, and may be repeated whenever there is occasion to give food. Though the experience of Dr. Stephenson has been mainly confined to children, yet he has also tried the remedy in adults presenting similar indications, and with encouraging results. In these cases he recommends from 20 to 40 grains to be given, dissolved in water, after meals. (*Edin. Med. Journ.*, Oct. 1867, p. 336.) Should Dr. Stephenson's experience be confirmed by that of other practitioners, he will have made a very important contribution to therapeutics. In the *Boston Med. and Surg. Journ.*, of Feb. 6, 1868 (*page* 5), is a communication from Dr. S. G. Webber, of Boston, giving details of several infantile cases, which, in the symptoms, treatment, and results, closely corresponded with those of Dr. Stephenson.

SODÆ VALERIANAS. *U. S., Br. Valerianate of Soda.*

"Take of Bichromate of Potassa, in fine powder, *ten troyounces;* Sulphuric Acid *fourteen troyounces;* Amylic Alcohol *four fluidounces;* Water *four pints;* Solution of Soda *a sufficient quantity.* Dissolve the Bichromate, with the aid of heat, in three pints of the Water, and add to the solution seven troyounces of the Sulphuric Acid, previously diluted with the remainder of the Water. Pour the liquid into a tubulated retort, to which a receiver is attached without luting. Mix the Amylic Alcohol with the remainder of the Sulphuric Acid, gradually added, and, by means of a funnel-shaped tube, passing through a cork in the tubulure of the retort and dipping into the liquid, introduce the mixture, when cool, into the retort, in small portions at a time, until it is all added. Return to the retort any liquid which may have spontaneously distilled over, and agitate the whole until the reaction has subsided, and the temperature

has fallen to about 100°. Then, by means of a sand-bath, distil the liquid nearly to dryness. Introduce the distilled liquid into a capacious glass matrass, and add to it Solution of Soda, with frequent agitation, until it is accurately saturated. Separate the oil that floats on the liquid, and evaporate the latter until aqueous vapour ceases to escape, and nothing remains but the salt in a state of fusion. Lastly, pour the fused salt on a porcelain slab, and, after it has concreted, break the mass while yet warm in pieces, and keep these in a well-stopped bottle." *U. S.*

"Take of Amylic Alcohol (Fousel Oil) *four fluidounces* [Imperial measure]; Bichromate of Potash *nine ounces* [avoirdupois]; Sulphuric Acid *six fluidounces and a half* [Imp. meas.]; Solution of Soda *a sufficiency;* Distilled Water *half a gallon* [Imp. meas.]. Dilute the Sulphuric Acid with ten fluidounces of the Water, and dissolve the Bichromate of Potash in the remainder of the Water with the aid of heat. When both liquids are cold, mix them with the Fousel Oil in a matrass, with occasional brisk agitation, until the temperature of the mixture has fallen to about 90°. Connect the matrass with a condenser, and distil until about half a gallon of liquid has passed over. Saturate the distilled liquid accurately with the Solution of Soda, remove any oil which floats on the surface, evaporate till watery vapour ceases to escape, and then raise the heat cautiously so as to liquefy the salt. When the product has cooled and solidified, break it into pieces, and immediately put it into a stoppered bottle." *Br.*

These processes are essentially the same as that of the late Dublin Pharmacopœia, into which the preparation was introduced in 1850. They consist of two steps; first, the artifical formation of valerianic acid, and secondly, the saturation of this acid with caustic soda. By distilling fusel oil with a mixture of sulphuric acid and bichromate of potassa, valerianic acid is formed, and passes over with water. The change is effected by the oxidizing agency of the chromic acid of the bichromate; for when fusel oil loses two eqs. of hydrogen by oxidation, and gains two of oxygen, it is converted into valerianic acid. Thus, $C_{10}H_{11}O + HO$ and $4O = C_{10}H_9O_3 + HO$ and $2HO$. (See *Potassæ Bichromas* and *Alcohol Amylicum.*) The distillate, by exact saturation with the solution of caustic soda, is converted into a solution of valerianate of soda, which, by the application of heat until the water is driven off, and the residual matter is partially liquefied, furnishes, on cooling, the concrete salt. The small portion of oil that floats on the surface of the solution is valerianate of amylic ether ($C_{10}H_{11}O,C_{10}H_9O_3$).

Properties, &c. Valerianate of soda is a deliquescent, very soluble salt, in snow-white masses, having the disagreeable odour of valerianic acid, and a taste at first styptic, but afterwards sweetish. When heated to 285°, it fuses without loss of acid, and, upon cooling, concretes into a white solid. The salt, as officinally ordered, is in the form produced by fusion. It consists of one eq. of valerianic acid and one of soda ($NaO,C_{10}H_9O_3$). It is little used medically, having been originally introduced into the Dublin officinal catalogue for the sole purpose of forming, by double decomposition, the valerianates of iron, quinia, and zinc, and retained in the U. S. and Br. Pharmacopœias for the preparation of the last-mentioned salt. It may, however, be given as a nervous stimulant in the dose of from one to five grains.

SPIRITUS.

Spirits.

Spirits, as the term is here used, are alcoholic solutions of volatile principles, formerly in general procured by distillation, but now frequently prepared by simply dissolving the volatile principle in alcohol or diluted alcohol. The distilled spirits are prepared chiefly from aromatic vegetable substances, the essential oils of which rise with the vapour of alcoho , and condense with it in the

receiver. Some of the oils, however, will not rise at the temperature of boiling alcohol, but may be distilled with water. In this case, it is necessary to employ proof spirit or diluted alcohol, with the water of which the oil comes over in the latter part of the process. As the proof spirit of the shops is often impregnated with foreign matters, which give it an unpleasant flavour, it is better to use alcohol which has been carefully rectified, and to dilute it with the due proportion of water, as directed by the U. S. Pharmacopœia. In preparing the spirits, care should be taken to avoid the colour and empyreumatic flavour arising from the decomposition of the vegetable matter by heat. Sufficient water must, therefore, be added to cover the vegetable matter after the alcohol shall have been distilled; and, as a general rule, the heat should be applied by means of a water-bath, or of steam. The aromatic should be macerated for some days with the alcohol, before being submitted to distillation; as the oil, being thus dissolved, rises more readily with the spirituous vapour than when confined in the vegetable tissue. It is necessary, during the process, frequently to renew the water in the refrigeratory; as otherwise much of the vapour will escape condensation. A good apparatus for the purpose is described and figured in *page* 925.

The aromatic spirits are used chiefly to impart a pleasant odour and taste to mixtures, and to correct the nauseating and griping effects of other medicines. They serve also as carminatives in flatulent colic, and agreeable stimulants in debility of stomach; but their frequent use may lead to the formation of intemperate habits, and should, therefore, be avoided.

We follow the example of the Pharmacopœias, in considering in the present class several articles, which, though with the title of spirit, were formerly arranged with the substances which constitute their active ingredients, as the spirits of ammonia, ether, and nitrous ether. The Spirits, formerly officinal, which have been omitted in the present U. S. and Br. Pharmacopœias, are *Spiritus Carui*, Lond., Ed., *Spiritus Cassiæ*, Ed., and *Spiritus Pulegii*, Lond. W.

SPIRITUS ÆTHERIS. *Br. Spirit of Ether.*

"Take of Ether *ten fluidounces;* Rectified Spirit *one pint* [Imperial measure]. Mix. The specific gravity 0·809." *Br.*

This preparation is merely ether, diluted with twice its volume of alcohol. When prepared with materials of proper strength, its sp. gr. is 0·809. Its medical properties are similar to those of ether. The dose is from one to three fluidrachms, given with a sufficient quantity of sweetened water

Off. Prep. Tinctura Lobeliæ Ætherea, *Br.* B.

SPIRITUS ÆTHERIS COMPOSITUS. *U. S. Compound Spirit of Ether. Hoffmann's Anodyne Liquor.*

"Take of Ether *half a pint;* Alcohol *a pint;* Ethereal Oil *six fluidrachms.* Mix them." *U. S.*

This preparation is an alcoholic solution of ether, impregnated with heavy oil of wine. In the formula, determinate measures of ether, alcohol, and oil are taken, the ether having half the volume of the alcohol. The proportion of ethereal oil has been doubled in the present edition of the U. S. Pharmacopœia; but as the oil, as now prepared, is diluted with its bulk of ether, the oleaginous strength of the compound spirit is really the same. In the late revision of the British Pharmacopœias, and their consolidation into one, this preparation has been omitted; unfortunately, we think, as there is scarcely a doubt that the influence of the ether, as a composing medicine in nervous disorder, is much increased by the oil of wine.

Compound spirit of ether is a colourless, volatile liquid, having a burning, slightly sweetish taste, and the peculiar odour of ethereal oil. If it has an empyreumatic odour, it has been badly prepared. Its sp. gr. is 0·815, according to the U. S. Pharmacopœia. When pure it is wholly volatilized by heat, and devoid of acid reaction. It becomes milky on being mixed with water, owing to the precipitation of the ethereal oil; but this change does not prove its goodness, as the same property may be given to the spirit of ether by the addi-

tion of various fixed oils. This sophistication may be detected, according to Prof. Procter, by mixing the suspected preparation with water, drawing a piece of paper over the surface of the liquid to absorb the oily globules, and exposing the paper to heat. If the globules are fixed oil, the greasy stain will remain; if ethereal oil, the stain will disappear. When fixed oils are used to adulterate this preparation, the milkiness is generally too great, and not like the translucent, leaden milkiness of the genuine article. (*Dr. Squibb.*) "It gives only a slight cloudiness with chloride of barium; but when a fluidounce of it is evaporated to dryness with an excess of this test, it yields a precipitate [residue] of sulphate of baryta, which, when washed and dried, weighs 6·25 grains. When a few drops are burned on glass or porcelain, there is no visible residue, but the surface will be left with an acid taste and reaction. A pint of water, by the admixture of forty drops, is rendered slightly opalescent." *U. S.*

It is much to be regretted that our manufacturing chemists do not follow the Pharmacopœia in making Hoffmann's anodyne. In rectifying crude ether, the distillation is continued as long as the ether comes over of the proper specific gravity; after which, the manufacturer has been in the habit of changing the receiver, and obtaining an additional distillate, consisting of ether and alcohol, impregnated with a little ethereal oil. Now it is this second distillate, variously modified by the addition of alcohol, ether, or water, so as to make it conform in taste, smell, opalescence, &c. to a standard preparation, kept by the manufacturer, that is sold as Hoffmann's anodyne. (See Prof. Procter's paper on Hoffmann's anodyne in the *Am. Journ. of Pharm.* for July, 1852, p. 213.) Nothing could be more uncertain in its results than a proceeding like this; and we cannot be surprised that the medicine, as obtained from different apothecaries, varies very much in properties, and often disappoints the expectations of the physician. The chief excuse for the departure from the officinal directions is the costliness of the ethereal oil; but were this much greater than it really is, the excuse would not be valid; and it cannot be justified, on any principle of morality, to sell under the officinal title a preparation which has no claim to it whatever.

Medical Properties. This preparation is intended as a substitute for the anodyne liquor of Hoffmann, which it closely resembles when properly prepared. In addition to the stimulating and antispasmodic qualities of the ether which it contains, it possesses anodyne properties, highly useful in nervous irritation, and want of sleep from this cause. These additional virtues are probably derived from the officinal oil of wine, which is a more important substance than is generally supposed. Mr. Brande believes that the only effect of it, in the preparation under notice, is to alter the flavour of the ether. In this opinion he is certainly in error. The late Drs. Physick and Dewees of this city found the officinal oil of wine, dissolved in alcohol, very efficacious in certain disturbed states of the system, as a tranquillizing and anodyne remedy. Such indeed are the generally admitted effects of Hoffmann's anodyne, when made with a due admixture of the ethereal oil. This preparation is on many occasions a useful adjunct to laudanum, to prevent the nausea which is excited by the latter in certain habits. The dose is from thirty minims to one or two fluidrachms, given in water sweetened with sugar. B.

SPIRITUS ÆTHERIS NITROSI. *U.S.*, *Br.* Spiritus Ætheris Nitrici. *U.S.* 1850. Spiritus Nitri Dulcis. *Spirit of Nitrous Ether. Sweet Spirit of Nitre.*

"Take of Nitric Acid *nineteen troyounces and a half;* Stronger Alcohol *nine pints;* Carbonate of Potassa *a troyounce.* Introduce four pints of the Alcohol into a retort, having the capacity of eight pints, and containing some pieces of glass, and add the Nitric Acid. Adapt the retort to Liebig's condenser, and apply heat by means of a water-bath so arranged that the water may be drawn off during the process. When the mixture boils briskly, draw off almost all the water of the bath, and allow the distillation to proceed spontaneously until it begins to slacken. Then cautiously reapply heat by means of the

water-bath, and continue the distillation until four pints of the distilled liquid have passed over. Having thrown away the residue, rinse the apparatus thoroughly, return the liquid to the retort, add the Carbonate of Potassa to it, agitate the mixture, and again distil by means of a water-bath, slowly at first, until three pints and a half of distilled liquid have been obtained. With this mix thoroughly the remainder of the Alcohol, and transfer the mixture to half-pint bottles, which must be well stopped, and protected from the light. Spirit of Nitrous Ether has the sp. gr. 0·837, and contains from 4·3 to 5 per cent. of its peculiar ether. It should not be kept long, as it becomes strongly acid by age." *U. S.*

"Take of Nitric Acid *three fluidounces* [Imperial measure]; Sulphuric Acid *two fluidounces* [Imp. meas.]; Copper, in fine wire (about No. 25), *two ounces* [avoirdupois]; Rectified Spirit *a sufficiency.* To one pint of the Spirit add gradually the Sulphuric Acid, stirring them together; then add in the same way, two and a half fluidounces of the Nitric Acid. Put the mixture into a retort or other suitable apparatus, into which the Copper has been introduced, and to which a thermometer is fitted. Attach now an efficient condenser, and applying a gentle heat, let the spirit distil at a temperature commencing at 170°, and rising to 175°, but not exceeding 180°, until twelve fluidounces have passed over and been collected in a bottle kept cool, if necessary, with ice-cold water; then withdraw the heat, and having allowed the contents of the retort to cool, introduce the remaining half ounce of Nitric Acid, and resume the distillation as before, until the distilled product has been increased to 15 fluidounces. Mix this with two pints of the Rectified Spirit, or as much as will make the product correspond to the tests of specific gravity and percentage of ether separated by chloride of calcium. Preserve it in well-closed vessels." *Br.*

The officinal spirit of nitrous ether is a mixture, in variable proportions, of nitrous ether (C_4H_5O,NO_3) and alcohol (rectified spirit). Nitrous ether is always generated by the reaction of nitric acid with alcohol; and it matters not whether the alcohol be mixed with nitric acid directly, or with the materials for generating it, namely, nitre and sulphuric acid. In the former U. S. Pharmacopœia the requisite nitric acid was obtained by using the materials for generating it; nitrate of potassa, namely, and sulphuric acid. The formula was modelled after a recipe communicated by Mr. John Carter, manufacturing chemist, to the Philadelphia College of Pharmacy, and recommended for adoption by a committee of that body.* The nitre and alcohol being mixed in the retort, the sulphuric acid was gradually added, and a gentle heat applied. Nitric acid was set free, and by reacting with a part of the alcohol produced the nitrous ether. Upon the subsequent increase of the heat, the ether and the remainder of the alcohol distilled over as sweet spirit of nitre. The distilled product, however, contained some acid, and hence was rectified by a distillation from carbonate of potassa. Diluted alcohol was added before commencing this distillation, to enable the operator to obtain a quantity of distilled product equal to that procured at first, without distilling to dryness, which would endanger the production of empyreuma. The alcohol was first mixed with the nitre, in the retort, and the sulphuric acid afterwards gradually added. Had the alcohol and sulphuric acid been previously mixed, the risk would have been run of generating ether before their addition to the nitre. In repeating this process the retort employed should be capable of holding twice the amount of the materials. The sweet spirit of nitre, obtained by the old formula, was estimated to contain 4 per cent. in volume of nitrous ether.

The above process, as conducted by Mr. Carter on a large scale, was performed

* The following is the formula of the U. S. Pharmacopœia of 1850. "Take of Nitrate of Potassa, in coarse powder, *two pounds;* Sulphuric Acid *a pound and a half;* Alcohol *nine pints and a half;* Diluted Alcohol *a pint;* Carbonate of Potassa *an ounce.* Mix the Nitrate of Potassa and the Alcohol in a large glass retort, and having gradually poured in the Acid, digest with a gentle heat for two hours; then raise the heat and distil a gallon. To the distilled liquor add the Diluted Alcohol and Carbonate of Potassa, and again distil a gallon." *U. S.*

in a copper still of about twenty gallons capacity, and furnished with a pewter head and worm. The materials for the first distillation were 18 pounds of purified nitre, 12 gallons of alcohol of 34° Baumé (0·847), and 12 pounds of sulphuric acid; and 10 gallons were drawn off. The distilled product was then mixed with a gallon of diluted alcohol, and rectified by a new distillation from lime or a carbonated alkali; the same quantity being distilled as at first. When large quantities of this preparation are made, the several portions require to be mixed in a large glass vessel, to render the whole of uniform strength; as the portion which first comes over in the rectification is strongest in nitrous ether. Previously to the redistillation, the head and worm must be washed thoroughly with water, to remove a little acid which comes over in the first distillation. (*Journ. of the Phil. Col. of Pharm.*, i. 308.)

In the present U. S. process, which was modelled after the plan of Dr. Squibb, the nitric acid and alcohol are directly mixed in a retort containing pieces of glass to facilitate ebullition and prevent concussion, and arrangements are made for applying heat by means of a water-bath, so that it may be diminished when necessary to repress the violence of the reaction, and increased when this requires invigoration. The liquid condensed in the receiver is mixed with carbonate of potassa, and again distilled in order to free it from the acid which has come over with the nitrous ether; and, being too strong with ether to meet the purposes required, is diluted with alcohol, and thus brought to the state of *spirit* of nitrous ether. It is a great improvement over the old formula, and has the merit of ensuring a preparation of definite strength.

The former *British* process, which was a new one, consisted in distilling a mixture of *nitrite* of soda, alcohol, and sulphuric acid. Instead, therefore, of using nitric acid either directly or by the decomposition of nitre, it substituted nitrous acid from the nitrite of soda, separating it by means of sulphuric acid in the presence of alcohol, and thus bringing together the materials for forming the ether more nearly in the condition in which they are to exist in the ether when formed. But the intended results were not obtained by the process; for the nitrite of soda, prepared by the British formula for that salt, was a mixture containing only a small relative proportion of the proper nitrite, which, according to Mr. Squire, existed in it in variable quantities from 5 to 25 per cent.; so that the resulting spirit of nitrous ether necessarily was of uncertain strength. The present British formula rejects the nitrite of soda, but retains the principle of presenting the ingredients to each other in the form in which they are to exist in the spirit when formed; the ether resulting from the action of sulphuric acid on alcohol, and the nitrous acid from that of the copper on the nitric acid uniting to form nitrous ether, which, having been distilled over, is brought to the state of spirit of ether by admixture with somewhat less than three volumes of alcohol. From the reports of the English pharmaceutists, it would appear that the present Br. process has proved, in practice, to be quite satisfactory. Professor Attfield says that "the junior students were always able to make a satisfactory preparation by following the directions of that formula." (*Pharm. Journ.*, Sept. 1868, p. 156.)

Theory of the Production of Nitrous Ether, &c. One eq. of nitric acid, by reacting with one eq. of alcohol, forms one eq. of nitrous acid (formerly hyponitrous), one eq. of *aldehyd* ($C_4H_4O_2$), and two eqs. of water. Thus, NO_5 and $C_4H_6O_2 = NO_3$ and $C_4H_4O_2$ and $2HO$. The nitrous acid, as soon as formed, reacts with a second eq. of alcohol, so as to form one eq. of nitrous ether, with separation of one eq. of water. It has, however, been shown by Dr. Golding Bird that, when an excess of alcohol is used, *oxalhydric* (*saccharic*) *acid* is first formed, and that, when the formation of the nitrous ether has nearly ceased, aldehyd appears in the distilled product, and simultaneously oxalic acid in the contents of the retort, before which time the latter cannot be discovered. All these products result from the oxidizing action of the nitric acid upon the alcohol, increasing the proportion of oxygen in the substances formed, either by removing the hydrogen, or by abstracting this element and adding oxygen at the same time.

Properties of Nitrous Ether. *Pure* nitrous (hyponitrous) ether is pale-yellow, has the smell of apples and Hungary wines, boils at 62° (below 65° Hare), and has the sp. gr. 0·947 at 60°. The density of its vapour is 2·627. Litmus is not affected by it. When it is mixed with an alcoholic solution of potassa, hyponitrite of potassa and alcohol are formed, without producing a brown colour, showing the absence of aldehyd. It is soluble in 48 parts of water, and in all proportions in alcohol or rectified spirit. It is highly inflammable, and burns with a white flame without residue. The *impure* ether, as formerly obtained by the Edinburgh and Dublin processes for subsequent dilution to form sweet spirit of nitre, boiled at 70°, and had the density of 0·886 at 40°. The specific gravity assigned to it by the Edinburgh College was 0·899. Mixed with an alcoholic solution of potassa, it became dark-brown, with production of *aldehyd resin.* (See *page* 15.) This discoloration showed the presence of aldehyd. When kept it became acid in a short time, as shown by litmus; and nitric oxide was given off, which often caused the bursting of the bottle. Its tendency to become acid was rendered greater by the action of the air, and depended on the absorption of oxygen by the aldehyd, which thereby became acetic acid. These facts evince the propriety of preserving this ether in small, strong bottles, kept full and in a cool place. Nitrous ether consists of one eq. of nitrous acid and one of ether, and its formula is C_4H_5O,NO_3. It was, therefore, improperly called *nitric ether.* Considered as a salt, its proper name is *nitrite of ether.* In its pure and concentrated state it is never used in medicine.

Properties of Spirit of Nitrous Ether. This is a pale-yellow, volatile liquid, of a fragrant ethereal odour, and pungent, aromatic, sweetish, acidulous taste. As usually prepared it slightly reddens litmus, but does not cause effervescence with carbonate of soda. Its officinal sp. gr. is 0·837, *U. S.;* 0·845, *Br.* The U. S. preparation contains from 4·3 to 5 per cent of the proper nitrous ether. It keeps well in half-pint bottles, securely stopped with waxed glass stoppers, and covered with dark paper; as Dr. Squibb proved by examining some bottles thus put up, after the lapse of two years. High density is not necessarily an index of deficient strength; since it may arise from the presence of a large proportion of nitrous ether. When heated by means of a water-bath, the U. S. sweet spirit of nitre begins to boil at about 145°. If a test tube, half filled with the U. S. spirit, be plunged into water heated to 145°, and held there until its contents acquire that temperature, the spirit will begin to boil distinctly on the addition of a few small pieces of glass. (*U. S.*) Sweet spirit of nitre mixes with water and alcohol in all proportions. It is very inflammable, and burns with a whitish flame. It should not be kept long, as it becomes strongly acid with age. The *Br.* Pharmacopœia states, in regard to its own preparation, that, "when agitated with solution of sulphate of iron and a few drops of sulphuric acid, it becomes deep olive-brown or black;" and that "if it be agitated with twice its volume of saturated solution of chloride of calcium in a closed tube, two per cent. of its original volume will separate in the form of nitrous ether and rise to the surface of the mixture." *Br.* This indicates a strength considerably less than that of the U. S. spirit.

Impurities and Tests. Sweet spirit of nitre is never quite free from aldehyd; and, if the distillation be too long continued, it is apt to contain a good deal of this substance, which afterwards becomes acetic acid by absorbing oxygen. The change goes on rapidly if the preparation be insecurely kept. Aldehyd, if in considerable proportion, may be detected by imparting a pungent odour and acrid flavour, and by the preparation assuming a brown tint on the addition of a weak solution of potassa, owing to the formation of aldehyd resin. The potassa test, with the best specimens, produces a straw-yellow tint within twelve hours. "When mixed with half its volume of officinal solution of potassa, previously diluted with an equal measure of distilled water, it assumes a yellow colour, which slightly deepens without becoming brown, in twelve hours." *U. S.* Another test for aldehyd, less reliable, is the addition of an equal volume of sulphuric acid to the sweet spirit of nitre. If the sample be good, the change of

colour will be slight, and the mixture will be considerably viscid ; but if it contain much aldehyd, it will become dark-coloured. If water or spirit be present in undue proportion, the viscidity will be less. (*Phillips.*) Acetic acid, as well as other acids (usually nitrogen acids) that may happen to be present, may be discovered by the taste, by their acting on litmus strongly, and by their decomposing the alkaline carbonates or bicarbonates with effervescence. Nitrogen acids are known by colouring blue a piece of paper previously dipped into tincture of guaiac. These acids operate injuriously by their chemical reactions with other substances, when spirit of nitre is prescribed in mixtures. Thus, they liberate iodine from iodide of potassium, gradually decolorize compound infusion of roses, and in the compound mixture of iron, hasten the conversion of protoxide of iron into sesquioxide. To obviate these effects, Mr. Harvey, of Leeds, keeps sweet spirit of nitre standing on crystals of bicarbonate of potassa, and states that, if the preparation be of full strength, no appreciable portion of the alkali will be dissolved. (*Pharm Journ.*, Jan. 1842.) When acid sweet spirit of nitre is rectified from calcined magnesia, it becomes acid again in a short time ; but, according to M. Klauer, when rectified from neutral tartrate of potassa, it continues unchanged for months. A deep-olive colour with sulphate of protoxide of iron shows the presence of a nitrogen oxide or acid.

According to Mr. Bastick, sweet spirit of nitre contains about one-fifth of one per cent. of anhydrous hydrocyanic acid, when made from nitrous (hyponitrous) ether, formed by impregnating alcohol with nitrous acid, evolved by the action of starch on nitric acid, according to the process of Liebig. In making sweet spirit of nitre on a large scale, Dr. Squibb found that hydrocyanic acid vapours were produced if the heat happened to rise too high, and the ether ceased to be formed.

Alcohol and water are often fraudulently added to sweet spirit of nitre. When in undue proportion, they may be detected in the British preparation, as stated in the Pharmacopœia, by agitating it with twice its volume of a saturated solution of chloride of calcium. If the sweet spirit of nitre be of the full strength, two per cent. of ether will slowly separate, and rise to the surface. If less ether or none separate, the presence of too much alcohol and water will be indicated. Specific gravity is no criterion of the goodness of the preparation as obtained by any formula. The addition of water will raise its density ; and the same effect will be produced by adding nitrous ether. A high density, in connection with deficient ethereal qualities, would of course indicate free acids, or an excess of water, or both. A specific gravity lower than the U. S. and Br. standard would show the presence of alcohol, either stronger than it should be, or in too large a proportion.

The fraudulent dilution of sweet spirit of nitre with alcohol and water is a great evil, considering its extensive use, and valuable remedial properties. Water is injurious, not merely as a diluent, but as the most efficient promoter of chemical changes. We have been informed that the medicine is variously diluted with twice, thrice, and even four times its weight of alcohol and water. In this way its ether strength is often reduced to less than half what it should be. Dr. Squibb examined six samples of sweet spirit of nitre, five of which were obtained from respectable wholesale druggists ; and of these one sample contained 3·16 per cent. of nitrous ether, four between one and two per cent., and one under one per cent ; while a standard preparation, made according to the U. S. Pharmacopœia, contained at least 4·3 per cent. In some shops a strong and a weak preparation are kept, to suit the views of customers as to price. Some druggists are said to dilute their sweet spirit of nitre, upon the plea that the physician's prescriptions are written in view of the use of a weak preparation ! All these evils would be corrected, if the manufacturing chemists of the Union would prepare it by the formula of the U. S. Pharmacopœia, at the same time adopting measures necessary to preserve it from change. A uniform preparation being thus furnished to the druggists, all that would be necessary on their part, would be to refrain from weakening it by the admixture of alcohol and water.

Medical Properties and Uses. Sweet spirit of nitre is diaphoretic, diuretic,

and antispasmodic. It is deservedly much esteemed as a medicine, and is extensively employed in febrile affections, either alone or in conjunction with tartar emetic for the purpose of promoting the secretions, especially those of sweat and urine. It often proves a grateful stimulus to the stomach, relieving nausea and removing flatulence, and not unfrequently quiets restlessness and promotes sleep. On account of its tendency to the kidneys, it is often conjoined with other diuretics, such as squill, digitalis, acetate of potassa, nitre, &c., for the purpose of promoting their action in dropsical complaints. Dr. Duncan, of Edinburgh, praised a combination of it with a small proportion of aromatic spirit of ammonia, as eminently diaphoretic and diuretic, and well suited to certain states of febrile disease. The dose is from thirty minims to a fluidrachm, every two or three hours, mixed with a portion of water. When used as a diuretic, it should be given in larger doses.

When the vapour of sweet spirit of nitre is inhaled, it produces, according to Mr. D. R. Brown, of Edinburgh, among other symptoms, a leaden-purple colour of the lips, mouth, hands, &c., and extreme muscular debility, enduring for hours. In his own case, these symptoms were unaccompanied with the slightest effect on the brain; but in others the effects were different; headache being invariably produced. (*Pharm. Journ.*, March, 1857, p. 456.)*

Off. Prep. Mistura Glycyrrhizæ Composita, *U. S.* B

SPIRITUS AMMONIÆ. *U. S. Spirit of Ammonia.*

"Take of Muriate of Ammonia, in small pieces, Lime, each, *twelve troyounces;* Water *six pints;* Alcohol *twenty fluidounces.* Upon the Lime, in a convenient vessel, pour a pint of the Water, and stir the mixture so as to bring it to the consistence of a smooth paste. Then add the remainder of the Water, and mix it well with the Lime. Decant the milky liquid from the gritty sediment into a glass retort, of the capacity of sixteen pints, and add the Muriate of Ammonia. Place the retort on a sand-bath, and adapt to it a receiver, previously connected with a two-pint bottle containing the Alcohol, by means of a glass tube reaching nearly to the bottom of the bottle. Surround the bottle with ice cold water; and apply a gradually increasing heat until ammonia ceases to be given off. Lastly, remove the liquid from the bottle, and introduce it into small bottles, which must be well stopped." *U. S.*

Spirit of ammonia is now officinal in the U. S. Pharmacopœia only; the British Pharmacopœia not having adopted it. It is a solution of caustic ammonia in rectified spirit. As prepared by the U. S. process of 1850, the ammoniacal gas was received in the alcohol and condensed by it; and the proportions of the ingredients were so adjusted as to give a preparation containing between 10 and 11 per cent. of ammonia, and capable of saturating about 30 per cent. of officinal sulphuric acid. Accordingly it agreed, as it was intended it should, in ammoniacal strength, with the U. S. *Liquor Ammoniæ.* Its sp. gr. was 0·831, or thereabouts. But, in the present officinal process, the materials for the generation of ammonia are mixed with a large proportion of water, the vapour of which comes over to some extent with the gas, and is condensed along with it. The resulting spirit is, therefore, somewhat diluted with water, and to an indefinite extent, so that the preparation can have no precise sp. gr.; and, though the whole amount obtained contains all the ammonia generated, we have no accurate criterion of its relative strength.

Properties. The *U. S.* spirit of ammonia, formerly called *ammoniated alcohol*, is a transparent colourless liquid, having a strong ammoniacal odour, and acrid taste. When good it does not effervesce with dilute muriatic acid; but, if old, or carelessly kept, it is apt to be partially carbonated, as shown by this test. It, however, absorbs carbonic acid more slowly than Liquor Ammoniæ.

* In relation to sweet spirit of nitre, the reader is referred to the paper of D. R. Brown, of Edinburgh, contained in the *Pharm. Journ.* (March, 1856, p. 400); also to an instructive practical paper by Dr. E. R. Squibb, U. S. Navy, published in the *Am. Journ. of Pharm.* (July, 1856, p. 289), from which we have freely drawn in revising this article.

Medical Properties and Uses. Spirit of ammonia is stimulant and antispasmodic, and is given in hysteria, flatulent colic, and nervous debility. It is, however, little used internally; the aromatic spirit, which is pleasanter and has similar properties, being preferred. The dose of the U. S. preparation is from ten to thirty drops in a wineglassful of water. Spirit of ammonia dissolves resins, gum-resins, camphor, and the volatile oils; and is a very convenient addition to spirituous liniments, intended to produce a rubefacient effect. Not more than one part of the spirit should, as a general rule, be added to six or eight parts, by measure, of the liniment. It enters into no officinal preparation. B.

SPIRITUS AMMONIÆ AROMATICUS. *U.S.*, *Br.* *Aromatic Spirit of Ammonia.*

"Take of Carbonate of Ammonia *a troyounce;* Water of Ammonia *three fluidounces;* Oil of Lemons *two fluidrachms and a half;* Oil of Nutmeg *forty minims;* Oil of Lavender *fifteen minims;* Alcohol *a pint and a half;* Water *a sufficient quantity.* Dissolve the Carbonate in the Water of Ammonia, previously mixed with four fluidounces of Water. Dissolve the Oils in the Alcohol, mix the two solutions, and add sufficient Water to make the whole measure two pints." *U. S.*

"Take of Carbonate of Ammonia *eight ounces* [avoirdupois]; Strong Solution of Ammonia *four fluidounces;* Volatile Oil of Nutmeg *four fluidrachms;* Oil of Lemon *six fluidrachms;* Rectified Spirit *six pints* [Imperial measure]; Water *three pints* [Imp. meas.]. Mix, and distil seven pints [Imp. meas.]. Sp. gr. 0·870." *Br.*

In both of these formulas carbonate of ammonia and uncombined ammonia are used; but they differ in the relative proportion of the materials and the mode of conducting the process. The U. S. spirit is a mere solution of the ingredients in alcohol diluted with a small proportion of water; while the British contains such and so much of the ingredients as may rise in distillation, and be condensed with the seven pints of spirit that result. The former is of definite strength, the latter more or less indefinite, as a portion of the materials must be left behind. The proportion of ammonia to the carbonate (sesquicarbonate) is such as to produce a neutral carbonate. The sp. gr. of the Br. preparation is 0·870.

Medical Properties and Uses. Aromatic spirit of ammonia is fitted to fulfil the same indications as the simple spirit; but is much more used on account of its grateful taste and smell. It is advantageously employed as a stimulant antacid in sick headache. The dose of the U. S. spirit is from thirty drops to a fluidrachm, sufficiently diluted with water. Aromatic spirit of ammonia may be usefully added to aperient draughts, to render them less offensive to the stomach; but care must be taken not to mix it with incompatible substances; and, in order that these may be avoided, it must be recollected that most of the ammonia contained in it is probably in the state of the neutral carbonate.

Off. Prep. Tinctura Guaiaci Ammoniata; Tinctura Valerianæ Ammoniata. B.

SPIRITUS AMMONIÆ FŒTIDUS. *Br.* *Fetid Spirit of Ammonia.*

"Take of Assafœtida *one ounce and a half* [avoirdupois]; Strong Solution of Ammonia *two fluidounces* [Imperial measure]; Rectified Spirit *a sufficiency.* Break the Assafœtida into small pieces and macerate it, in a closed vessel, in fifteen fluidounces of the Spirit for twenty-four hours, then distil off the spirit, mix the product with the Solution of Ammonia, and add sufficient Rectified Spirit to make *one pint* [Imp. meas.]." *Br.*

This is an alcoholic solution of the volatile oil of assafetida mixed with strong water of ammonia, and is an energetic nervous stimulant and antacid, adapted to certain hysterical conditions, associated with gastric weakness and acidity. It is one of the preparations formerly recognised by the British Colleges, and taken up again in the existing edition of the Br. Pharmacopœia after having been dropped by the first. The dose is from thirty minims to a fluidrachm, to be largely diluted when administered. W.

SPIRITUS ANISI. *U. S.* Essentia Anisi. *Br.* *Spirit of Anise. Essence of Anise.*

"Take of Oil of Anise *a fluidounce;* Stronger Alcohol *fifteen fluidounces.* Dissolve the Oil in the Stronger Alcohol." *U. S.*

In the preparation of its Essence the British Pharmacopœia directs *one fluidounce* of the Oil to *four fluidounces* of Rectified Spirit.

The dose of the U. S. spirit, as a stomachic and carminative, is one or two fluidrachms, that of the Br. essence one-fourth as much. W.

SPIRITUS ARMORACIÆ COMPOSITUS. *Br.* *Compound Spirit of Horse-radish.*

"Take of Horse-radish Root, scraped, Bitter Orange Peel, cut small and bruised, of each, *twenty ounces* [avoirdupois]; Nutmeg, bruised, *half an ounce* [avoird.]; Proof Spirit *one gallon* [Imperial measure]; Water *two pints* [Imp. meas.]. Mix, and distil a gallon [Imp. meas.] with a moderate heat." *Br.*

This may be used advantageously as an addition to diuretic remedies, in dropsy attended with debility, especially in the cases of drunkards. The dose is from one to four fluidrachms. W.

SPIRITUS CAJUPUTI. *Br.* *Spirit of Cajuput.*

"Take of Oil of Cajuput *one fluidounce;* Rectified Spirit *forty-nine fluidounces.* Dissolve." *Br.*

For an account of the medical properties and uses of oil of cajeput, of which this is simply an alcoholic solution, see *Oleum Cajuputi*, in *Part* I. The dose of this spirit, which has only one-fifth of the strength of the Br. spirit of 1864, is from 30 minims to a fluidrachm. W.

SPIRITUS CAMPHORÆ. *U. S.*, *Br.* *Spirit of Camphor.* Tinctura Camphoræ. *U. S.* 1850. *Tincture of Camphor.*

"Take of Camphor *four troyounces;* Alcohol *two pints.* Dissolve the Camphor in the Alcohol, and filter through paper." *U. S.*

"Take of Camphor *one ounce* [avoirdupois]; Rectified Spirit *nine fluid ounces.* Dissolve." *Br.*

The former of these preparations is precisely the U. S. Tincture of Camphor of 1850, with a changed name. The British does not materially differ. This spirit is used chiefly as an anodyne embrocation in rheumatic and gouty pains, chilblains, and the inflammation resulting from sprains and bruises. M. Nélaton employs it, in the Clinical Hospital of Paris, in the dressing of open wounds, by compresses, lotion, or fomentation. (*Ann. de Thérap.*, 1865, p. 129.) It may also be employed internally, due regard being paid to the stimulant properties of the alcohol. The camphor is precipitated by the addition of water, but may be suspended by the intervention of sugar. The dose is from five drops to a fluidrachm, first added to sugar, and then mixed with water. W.

SPIRITUS CHLOROFORMI. *U. S.*, *Br.* *Spirit of Chloroform.*

"Take of Purified Chloroform *a troyounce;* Stronger Alcohol *six fluidounces.* Dissolve the Chloroform in the Stronger Alcohol." *U. S.*

"Take of Chloroform *one fluidounce;* Rectified Spirit *nineteen fluidounces.* Dissolve. Sp. gr. 0·871." *Br.*

The chloroform strength of these preparations is very different, the U. S. spirit having one measure of chloroform to between eight and nine of alcohol, the British one to nineteen. Solution of chloroform in alcohol in variable proportions was at one time erroneously called *chloric ether*, and was used as a respiratory anæsthetic agent in the place of chloroform, under the impression that it would be safer; the stimulant properties of the alcohol obviating the sedative action of the chloroform. It is at present, however, little if at all used in this way; they who employ chloroform, and yet wish to guard against its depressing effects, preferring ether to alcohol as the corrigent. The spirit of chloroform is a convenient form for internal exhibition, as it is more readily incorporated in mix-

tures than chloroform itself. The dose of the U. S. spirit is from half a fluidrachm to a fluidrachm; of the British, much more, in order to produce an equal effect; so much more, indeed, that the effect of the alcohol would neutralize in great measure that of the chloroform. The dose, however, as mentioned by British writers, is from ten to sixty minims; in which quantity, judging from our own experience, the chloroform would be of little use except for its flavour.* W.

SPIRITUS CINNAMOMI. *U.S. Spirit of Cinnamon.*

"Take of Oil of Cinnamon *a fluidounce;* Stronger Alcohol *fifteen fluidounces.* Dissolve the Oil in the Stronger Alcohol." U. S.

The spirit of cinnamon is an agreeable aromatic cordial, and may be given in debility of the stomach in the dose of from ten to twenty drops. W.

SPIRITUS JUNIPERI. *Br. Spirit of Juniper.*

"Take of Oil of Juniper *one fluidounce;* Rectified Spirit *forty-nine fluidounces.* Dissolve." *Br.*

This spirit is only of one-fifth of the strength of the Br. spirit of 1864, and contains about nineteen times as much Oil of Juniper as the London Spiritus Juniperi.

It is used chiefly as an addition to diuretic infusions. The dose may be from thirty to sixty minims.

Off. Prep. Mistura Creasoti, *Br.* W.

SPIRITUS JUNIPERI COMPOSITUS. *U.S. Compound Spirit of Juniper.*

"Take of Oil of Juniper *a fluidrachm and a half;* Oil of Caraway, Oil of Fennel, each, *ten minims;* Diluted Alcohol *eight pints.* Dissolve the Oils in the Diluted Alcohol." *U. S.*

This spirit is a useful addition to diuretic infusions and mixtures in debilitated cases of dropsy. The dose is from two to four fluidrachms. W.

SPIRITUS LAVANDULÆ. *U.S., Br. Spirit of Lavender.*

"Take of Lavender [flowers], fresh, *twenty-four troyounces;* Alcohol *eight pints;* Water *two pints.* Mix them, and with a regulated heat, distil eight pints." *U. S.*

"Take of Oil of Lavender *one fluidounce;* Rectified Spirit *forty-nine fluidounces.* Dissolve." *Br.*

Mr. Brande asserts that the dried flowers produce as fragrant a spirit as the fresh. Spirit of Lavender is used chiefly as a perfume, and as an ingredient in other preparations. The perfume usually sold under the name of *lavender water* is not a distilled spirit, but an alcoholic solution of the oil, with the addition of other odorous substances. The following is given by Mr. Brande as one of the

* *Alcoholic Solution of Chloroform.* The following observations formed a part of the article on chloroform in the eleventh edition of the Dispensatory; but with the changes in relation to this substance in the new U. S. Pharmacopœia, they find a more appropriate place here in the present edition. A preparation for inhalation, composed of one-third pure chloroform and two-thirds nearly absolute alcohol, was recommended by Dr. Warren, under the name of *strong chloric ether.* Dr. Snow has since employed a similar mixture, using equal parts of chloroform and alcohol. The mixture, made in the proportion adopted by Dr. Snow, is commended by M. Robert as the best anæsthetic agent yet proposed. As the name chloric ether was originally applied by the late Dr. T. Thomson, of Glasgow, to the Dutch liquid, it would be well to abandon the same appellation to designate chloroform, or its mixture with alcohol. A correct name for the latter would be *alcoholic solution of chloroform*, or *tincture of chloroform.* Dr. Warren used his preparation in fifty cases with success, and considered it safer than chloroform, and more agreeable than ether. Further observation is required to determine the value of "strong chloric ether" as an anæsthetic. The alcohol may prove useful by obviating, through its stimulant properties, the depressing influence of the chloroform; and ether has been occasionally mixed with chloroform, with the same view. The preparation, sold in London and elsewhere under the name of "chloric ether," is a weak tincture of chloroform of variable quality, containing at most but 16 or 18 per cent. of chloroform, and sometimes not more than 5 or 6 per cent. B.

most approved recipes for preparing it. "Take of rectified spirit five gallons. essential oil of lavender twenty ounces, essential oil of bergamot five ounces, *essence of ambergris* [made by digesting one drachm of ambergris and eight grains of musk in half a pint of alcohol] half an ounce. Mix." The *Br.* spirit is of one-fifth of the strength of the preparation of the Pharmacopœia of 1864. The dose may be from thirty minims to a fluidrachm.

Off. Prep. Mistura Ferri Composita, *U. S.* W.

SPIRITUS LAVANDULÆ COMPOSITUS. *U. S.* TINCTURA LAVANDULÆ COMPOSITA. *Br. Compound Spirit of Lavender. Compound Tincture of Lavender.*

"Take of Oil of Lavender *a fluidounce;* Oil of Rosemary *two fluidrachms;* Cinnamon, in moderately fine powder, *two troyounces;* Cloves, in moderately fine powder, *half a troyounce;* Nutmeg, in moderately fine powder, *a troyounce;* Red Saunders, in moderately fine powder, *three hundred and sixty grains;* Alcohol *six pints;* Water *two pints;* Diluted Alcohol *a sufficient quantity.* Dissolve the Oils in the Alcohol, and add the Water. Then mix the powders, and, having moistened the mixture with a fluidounce of the alcoholic solution of the Oils, pack it firmly in a conical percolator, and gradually pour upon it the remainder of the alcoholic solution, and afterwards Diluted Alcohol, until the filtered liquid measures eight pints." *U. S.*

The British Pharmacopœia takes *a fluidrachm and a half* of oil of lavender, *ten minims* of oil of rosemary, *one hundred and fifty grains* of bruised cinnamon, *the same quantity* of bruised nutmeg, *three hundred grains* of red saunders, and *two pints* (Imperial measure) of rectified spirit; macerates the solids in the spirit for seven days; then expresses, filters, dissolves the oils, and adds sufficient rectified spirit to make *two pints.*

When properly made, this is a delightful compound of spices. It is much employed as an adjuvant and corrigent of other medicines, and as a remedy for gastric uneasiness, nausea, flatulence, and general languor or faintness. The dose is from thirty drops to a fluidrachm, and is most conveniently administered on a lump of sugar, or mixed with sugar and water in a wineglass.

Off. Prep. Liquor Arsenicalis, *Br.;* Liquor Potassæ Arsenitis, *U. S.* W.

SPIRITUS LIMONIS. *U. S. Spirit of Lemon. Essence of Lemon.*

"Take of Oil of Lemon *two fluidounces;* Lemon Peel, freshly grated, *a troyounce;* Stronger Alcohol *two pints.* Dissolve the Oil in the Stronger Alcohol, add the Lemon Peel, macerate for twenty-four hours, and filter through paper." *U. S.*

This spirit is used chiefly for flavouring mixtures. W.

SPIRITUS MENTHÆ PIPERITÆ. *U. S., Br.* TINCTURA OLEI MENTHÆ PIPERITÆ. *U. S.* 1850. *Spirit of Peppermint. Tincture of Oil of Peppermint. Essence of Peppermint.*

"Take of Oil of Peppermint *a fluidounce;* Peppermint, in coarse powder, *one hundred and twenty grains;* Stronger Alcohol *fifteen fluidounces.* Dissolve the Oil in the Stronger Alcohol, add the Peppermint, macerate for twenty-four hours, and filter through paper." *U. S.*

"Take of Oil of Peppermint *one fluidounce;* Rectified Spirit *forty-nine fluidounces.* Dissolve." *Br.* This spirit is only of one-fifth of the strength of the Br. spirit of 1864, and contains about nine times as much Oil of Peppermint as Spiritus Menthæ Piperitæ of the London Pharmacopœia.

Under the name of ESSENTIA MENTHÆ PIPERITÆ, or *Essence of Peppermint*, the present Br. Pharmacopœia contains a preparation much stronger than either of the above spirits, consisting of *one fluidounce* of Oil of Peppermint to *four fluidounces* of Rectified Spirit.

The distilled spirit has no advantage over a simple solution of the oil in alcohol, and this mode of preparing it has been adopted both in the U. S. and British Pharmacopœias. The present officinal spirit is the Tincture of Oil of

Peppermint of the U. S. Pharmacopœia of 1850; and is much stronger than the old distilled spirit. It has long been popularly used under the name of *essence of peppermint.* The present preparation is only about half as strong as the former tincture, and differs in having a little of the dried herb added to the oil, the object of which, as we are informed, is to impart colour to the spirit. The spirit of peppermint affords a convenient method of administering a dose of the volatile oil; being of such a strength that, when dropped on loaf-sugar, it may be taken without inconvenience. The dose is from twenty to thirty drops, which may be given as just mentioned, or mixed with sweetened water. The dose of the British Spirit is from thirty minims to a fluidrachm, that of the British Essence from ten to twenty minims. W.

SPIRITUS MENTHÆ VIRIDIS. *U. S.* TINCTURA OLEI MENTHÆ VIRIDIS. *U. S.* 1850. *Spirit of Spearmint. Tincture of Oil of Spearmint. Essence of Spearmint.*

"Take of Oil of Spearmint *a fluidounce;* Spearmint, in coarse powder, *one hundred and twenty grains;* Stronger Alcohol *fifteen fluidounces.* Dissolve the Oil in the Stronger Alcohol, add the Spearmint, macerate for twenty-four hours, and filter through paper." *U. S.*

The remarks made on the Spirit of Peppermint are equally applicable to this. Both are usually employed as carminatives. The spirit of spearmint may be given in the dose of thirty or forty drops. W.

SPIRITUS MYRISTICÆ. *U. S., Br. Spirit of Nutmeg.*

"Take of Nutmeg, bruised, *two troyounces;* Diluted Alcohol *eight pints;* Water *a pint.* Mix them, and with a regulated heat, distil eight pints." *U. S.*

"Take of Volatile Oil of Nutmeg *one fluidounce;* Rectified Spirit *forty-nine fluidounces.*" *Br.*

The spirit of nutmeg is used chiefly for its flavour, as an addition to other medicines. The dose is one or two fluidrachms. That of the British spirit, which is only of one-fifth of the strength of that of 1864, is from thirty minims to a fluidrachm.

Off. Prep. Mistura Ferri Composita, *Br.* W.

SPIRITUS ROSMARINI. *Br. Spirit of Rosemary.*

"Take of Oil of Rosemary *one fluidounce;* Rectified Spirit *forty-nine fluidounces.* Dissolve." *Br.*

This spirit has only one-fifth of the strength of the Br. spirit of 1864, and contains about six times as much Oil of Rosemary as Spiritus Rosmarini of the London Pharmacopœia. It is a grateful perfume, and is used chiefly as an ingredient in lotions and liniments. W

STRYCHNIA.

Preparations of Strychnia.

STRYCHNIA. *U. S., Br. Strychnia.*

"Take of Nux Vomica, rasped, *forty-eight troyounces;* Lime, in fine powder, *six troyounces;* Muriatic Acid *three troyounces and a half;* Alcohol, Diluted Alcohol, Diluted Sulphuric Acid, Water of Ammonia, Purified Animal Charcoal, Water, each, *a sufficient quantity.* Macerate the Nux Vomica for twenty-four hours in sixteen pints of water, acidulated with one-third of the Muriatic Acid; then boil for two hours, and strain with expression through a strong muslin bag. Boil the residue twice successively in the same quantity of acidulated Water, each time straining as before. Mix the decoctions and evaporate to the consistence of thin syrup; then add the Lime previously mixed with a pint of Water, and boil for ten minutes, frequently stirring. Pour the whole into a double muslin bag, and, having thoroughly washed the precipitate, press, dry, and powder it. Treat the powder repeatedly with Diluted Alcohol, in order to remove the brucia, until the washings are but faintly reddened by nitric acid

Then boil it repeatedly with alcohol until deprived of its bitterness, mix the several tinctures, and distil off the Alcohol by means of a water-bath. Having washed the residue, mix it with a pint of Water, and, applying a gentle heat, drop in sufficient Diluted Sulphuric Acid to neutralize and dissolve the alkaloid. Then add Purified Animal Charcoal, and, having boiled the mixture for a few minutes, filter, evaporate, and set aside to crystallize. Dissolve the crystals in Water, and add sufficient Water of Ammonia to precipitate the Strychnia. Lastly, dry this on bibulous paper, and keep it in a well-stopped bottle." *U. S.*

"Take of Nux Vomica *one pound* [avoirdupois]; Acetate of Lead *one hundred and eighty grains;* Solution of Ammonia, Rectified Spirit, Distilled Water, each, *a sufficiency.* Subject the Nux Vomica for two hours to steam in any convenient vessel; chop or slice it; dry it in a water-bath or hot air chamber, and immediately grind it in a coffee mill. Digest the powder at a gentle heat for twelve hours with two pints [Imperial measure] of the Spirit and one of the Water, strain through linen, express strongly, and repeat the process twice. Distil off the Spirit from the mixed fluid, evaporate the watery residue to about sixteen [fluid]ounces, and filter when cold. Add now the Acetate of Lead, previously dissolved in Distilled Water, so long as it occasions any precipitate; filter; wash the precipitate with ten ounces of cold Water, adding the washings to the filtrate; evaporate the clear fluid to eight [fluid]ounces, and when it has cooled add the Ammonia in slight excess, stirring thoroughly. Let the mixture stand at the ordinary temperature for twelve hours; collect the precipitate on a filter, wash it once with a few ounces of cold Distilled Water, dry it in a water-bath or hot air chamber, and boil it with successive portions of Rectified Spirit, till the fluid scarcely tastes bitter. Distil off most of the Spirit, evaporate the residue to the bulk of about half an ounce, and set it aside to cool. Cautiously pour off the yellowish mother-liquor (which contains the brucia of the seeds) from the white crust of strychnia which adheres to the vessel. Throw the crust on a paper filter, wash it with a mixture of two parts of Rectified Spirit and one of Water, till the washings cease to become red on the addition of nitric acid; finally dissolve it by boiling it with an ounce of Rectified Spirit, and set it aside to crystallise. More crystals may be obtained by evaporating the mother-liquor." *Br.*

In preparing strychnia, the first step is properly to comminute the nux vomica. This may be done by rasping the seeds, or, as directed in the British Pharmacopœia, by first softening them by steam, then slicing, drying, and grinding them. The next object is to extract the strychnia. For this purpose, in the U. S. process, water is employed acidulated with muriatic acid; in the British, rectified spirit diluted with half its bulk of water. In the latter, the native igasurate of strychnia is taken up; in the former, the muriate, which is a very soluble salt. In the U. S. process, after a concentration of the infusion, the salt of strychnia is decomposed by lime, which precipitates the strychnia along with the excess of lime employed and impurities. The strychnia is extracted from the precipitate by boiling alcohol, and may be obtained in crystals by the concentration of the solution. But in this state it is much coloured and impure. To obviate these impurities in some degree, the British Pharmacopœia directs that the concentrated liquid should be treated with acetate of lead, which precipitates much of the contaminating matter, and then that the liquor, previously filtered, should be treated with ammonia, by which the strychnia is thrown down less impure than in the U. S. process. At this stage of the proceedings, the present U. S. Pharmacopœia directs that the precipitate, which, besides strychnia, contains also brucia and various impurities, should be freed from the latter alkaloid by repeated washing with cold diluted alcohol, in which brucia is much more soluble than strychnia. This is a great improvement upon the U. S. formula of 1850, in which the brucia was allowed to accompany the strychnia to the end of the process. In the U. S. process, the impure strychnia is converted into a sulphate by the addition of sulphuric acid, and precipitated again by ammonia; being, while in the state of the sulphate, decolorized by means of animal charcoal. The Br.

Pharmacopœia completes the process by washing the precipitate produced by ammonia with cold water, drying it, then exhausting it with alcohol, and concentrating the alcoholic solution. The strychnia now crystallizes, leaving most of the brucia in the mother-liquor. But, as some of the latter alkaloid still contaminates the product, the Pharmacopœia directs this to be washed with cold alcohol somewhat diluted, until the washings cease to give evidence of the presence of brucia by being reddened by nitric acid; thus accomplishing at the end of the process what was done in the U. S. formula at an earlier stage. To free the strychnia entirely from brucia requires repeated crystallizations, and a little of the latter principle is consequently almost always retained; but it is not injurious, as the effects of the two alkaloids upon the system are very similar. The bean of St. Ignatius yields strychnia more easily and more largely than nux vomica, but is less plentiful.*

If thought desirable, brucia may be in great measure separated from the strychnia of the shops, by dissolving the latter in very dilute nitric acid, filtering, and concentrating. Nitrate of brucia crystallizes in short, thick, dense prisms grouped together; nitrate of strychnia in radiated tufts of long, light, capillary needles. By gentle agitation with the liquid, the latter salt is suspended and may be poured off, leaving the former. The alkaloids may be obtained by dissolving the salts in water, and precipitating with ammonia. (*Christison.*)

* M. J. F. Molyn proposes, previously to the extraction of strychnia, to subject nux vomica to fermentation, by which the saccharine and gummy matters of the seeds are decomposed, and lactic acid is formed, which decomposes the igasurates of strychnia and brucia, producing with these bases very soluble lactates. For the particulars of his process, see the *Am. Journ. of Pharm.* (xix. 99).

We are informed that none of the officinal processes are followed exactly by the large manufacturers, in reference to the preliminary comminution of the nux vomica. The plan most approved is to macerate the whole seeds in dilute sulphuric acid, and to pass steam through them, under pressure, in a covered vat, lined with lead. The seeds softened in this way are then ground, and the pulp lixiviated or expressed. One advantage of the sulphuric acid, thus employed, is thought to be the conversion of the bassorin, which impedes the process, into soluble dextrin. The liquors are precipitated with lime, and the process completed as officinally directed. (*Note to the tenth edition.*)

Mr. John Horsley, of Cheltenham, England, proposes a new process for preparing strychnia, which has the advantage of dispensing with alcohol. One-quarter of a pound of nux vomica is kneaded with an equal weight of commercial acetic acid, the pulpy mass thus obtained is diluted with two or three pints of cold water, and the mixture is digested for a few days. The clear liquor is then decanted, an equal quantity of cold water poured on the mass, and digestion continued for a day or two longer, or till everything soluble has been extracted. The clear liquor is again decanted, and the residue filtered through flannel. The clear liquors are mixed, and evaporated to a syrupy consistence. The residue, when cold, is diluted with an equal quantity of water, ammonia is added in excess, and the mixture set aside for a day or two, that the strychnia may crystallize. This forms little white tufts in the liquid, and on the sides of the vessel. When the crystallization is complete, the supernatant liquid is filtered through calico, and the residue, with the impure crystals collected from the vessel added to it, is allowed to drain, then collected, and dried by means of a water-bath. The substance thus obtained, consisting of strychnia, brucia, and various impurities, is digested in hot diluted acetic acid, and the solution filtered. The strychnia and brucia may be precipitated from the filtered liquid by potassa; or, if the strychnia alone be wanted, a solution of chromate of potassa may be added, which will throw down chromate of strychnia, free from brucia, if the liquid be tolerably acid. The chromate of strychnia, being well drained on a filter, may be digested in solution of ammonia, by which the alkaloid will be precipitated of a more or less snowy whiteness. Mr. Horsley thus obtained about 1 per cent. of strychnia from nux vomica, which is at least twice the ordinary yield. (*Pharm. Journ.*, xvi. 179.)

Mr. John Williams proposes the use of benzole in the preparation of strychnia. Having extracted the soluble matters of nux vomica by repeated decoction with water acidulated with sulphuric acid, he evaporates the liquid to the consistence of thin treacle, and adds a concentrated solution of caustic potassa, so as to render the liquid strongly alkaline. He then adds an equal bulk of benzole, shakes the mixture well, and keeps it in a warm place for 12 hours. The benzole, holding the alkaloids in solution, rises, and is poured off; a new portion is added, and after similar treatment is also decanted; the mixed benzole solutions are distilled; and the residue treated with acetic acid, filtered, and precipitated with caustic soda. The precipitate is white, and consists of strychnia and brucia, which may be separated in the ordinary method. (See *Am. Journ. of Pharm.*, xxvi. 339.)—*Note to the eleventh edition.*

Properties. As usually kept in the shops, strychnia is a white or grayish-white powder. When rapidly crystallized from its alcoholic solution, it has the form of a white, granular powder; when slowly crystallized, that of elongated octohedra, or quadrilateral prisms with quadrilateral terminations. It is permanent in the air, inodorous, but excessively bitter, with a metallic after-taste. So intense is its bitterness, that one part of it is said to communicate a sensible taste to 600,000 parts of water. It melts like a resin, but has been supposed not to be volatile, being decomposed at a comparatively low temperature, and entirely dissipated at a red heat. Dr. Guy, however, has obtained from it a crystalline sublimate. He found it to sublime at a heat but a few degrees below that at which it begins to change colour and undergo decomposition. He gives its melting point at 345°, and that of sublimation at 430°. (*Pharm. Journ.*, Feb. 1868, p. 375.) According to Dr. Waddington, when heated to decomposition, it emits a most suffocating odour, resembling the smell of asphaltum. (*Ibid.*, March, 1868, p. 413.) It is soluble in 6667 parts of water at 50°, and about 2000 at the boiling point. Boiling officinal alcohol dissolves it without difficulty, and deposits it upon cooling. In absolute alcohol and in ether it is very sparingly soluble. According to the experiments of Messrs. Plummer and Kelly, strychnia is soluble, at the ordinary temperature, in 387 parts of officinal alcohol (sp. gr. 0·835), 179 parts of absolute alcohol, and 682 parts of ether. (*Am. Journ. of Pharm.*, Jan. 1859, p. 25.) The volatile oils dissolve it freely. Benzine dissolves 0·607 per cent. of it, and amylic alcohol 0·55 per cent. (Dragendorff, *Journ. de Pharm.*, 4e sér., iv. 473.) It has an alkaline reaction on test paper, and forms salts with the acids. Nitric acid does not redden it if perfectly pure, but almost always reddens it as found in the shops, in consequence of the presence of brucia. M. Eugene Marchand proposes the following test, by which a very minute proportion of strychnia may be detected. If a little of the alkaloid be rubbed with a few drops of concentrated sulphuric acid containing one-hundredth of nitric acid, it will be dissolved without change of colour; but if the least quantity of peroxide of lead be added to the mixture, a magnificent blue colour will be instantly developed, which will pass rapidly into violet, then gradually to red, and ultimately become yellow. (*Journ. de Pharm.*, 3e sér., iv. 200.) Professor Otto recommends as a test a minute quantity of solution of bichromate of potassa, which, added to the solution of strychnia in concentrated sulphuric acid, produces a splendid violet colour. (*Am. Journ. of Pharm.*, xix. 77.) A similar change of colour is produced, according to Dr. E. W. Davy, by substituting a strong solution of ferridcyanide of potassium (red prussiate of potassa) for that of bichromate of potassa. (*Ibid.*, xxv. 414.) It appears that any substance capable of yielding nascent oxygen readily will serve to develop the characteristic violet colour, when applied after the addition of sulphuric acid. Landerer has found that solid iodic acid or iodate of potassa, heated gently with strychnia, gives rise to a beautiful violet colour, gradually passing to red, which remains unchanged for many days. (*Ibid.*, March, 1861, p. 110.) According to Mr. Wm. Copney, the least efficacious agent is chlorate of potassa, a much better is deutoxide of lead, a still better is deutoxide of manganese, and the best of all is bichromate of potassa; and the general result of numerous experiments, recently made, is that the last-mentioned reagent is the most effective. The sulphuric acid must be of not less sp. gr. than 1·84; and that of 1·85 is better. The play of colours, according to Mr. Copney, is first blue, then purple, then crimson, which is followed by red and green, the latter sometimes giving place to yellow. It is stated that the 1-500,000th part of a grain may be detected. (See *Am. Journ. of Pharm.*, xxviii. 459.)* The usual mode of proceeding is to drop the solution

* This subject requires a more detailed consideration than space can be afforded for in the text. The questions have been discussed whether strychnia, taken in poisonous quantities, is decomposed after a short period in the system, so that it cannot be detected by chemical reagents either in the secretions or in the body; and whether, allowing it to remain in the system, the quantity required to produce death may not be so small, and so

suspected to contain strychnia upon a clean surface of porcelain, evaporate to dryness, then apply the sulphuric acid to the spot, and afterwards a minute fragment of a crystal of the bichromate, which will immediately produce the change of colour. Some doubt was thrown upon the value of this test by experiments, which seemed to prove that the presence of morphia in excess, es-

diffused, as to afford no evidence of its presence to chemical tests. The general results of the experiments upon these points are, that strychnia is found unaltered in the urine after being swallowed; that it strongly resists decomposition in the system; and that, in cases of poisoning, even though it may have been absorbed from the stomach, and not to be found there, it may be detected in the blood and solid tissues of the body, if taken largely enough to cause death.

But to succeed in detecting the alkaloid when mixed, in small proportion, with organic matters, it is necessary first so to disintegrate the organic matter that the action of a solvent of the strychnia should not be impeded, and that the alkaloid should be completely separated from the foreign matter. The process of Messrs. Rogers & Girdwood, by which these objects are effected, is the following. Digest the substance, supposed to contain the strychnia, with a mixture of 1 part of muriatic acid and 10 of water, until it becomes apparently fluid Filter, and evaporate the liquid to dryness by a water-bath. Treat the residue with alcohol as long as anything is dissolved, filter, and evaporate. Dissolve the residue in water and filter. Add solution of ammonia in excess to the aqueous solution, and agitate in a bottle or long tube with half an ounce of chloroform. Upon repose the chloroform subsides, holding the alkaloid in solution. Draw it off by a pipette, and evaporate the chloroform over a water-bath. Moisten the dry residue with concentrated sulphuric acid, and expose the mixture for some hours to the temperature of a water-bath, by which means all the organic matter except the strychnia is decomposed. Treat the charred mass with water, filter, add excess of ammonia, and shake the mixture with a drachm of chloroform. Separate the chloroform as before; and, if the matter left after the evaporation of a small portion of it is charred by concentrated sulphuric acid, the whole of it must be treated in the same manner as the previous chloroform solution. The last chloroform solution obtained is then to be tested for strychnia. Take up a little of it in a capillary tube, and drop it on the smallest space of a warm porcelain capsule, so that each successive drop may be evaporated. When the capsule is quite cold, moisten the spot with concentrated sulphuric acid, and add a minute fragment of bichromate of potassa. Should the characteristic colour not be developed, it is said that, if there be the minutest quantity of strychnia present, the colour will become visible by adding sulphuric acid rendered slightly yellow by chromic acid. In conducting the process, care must be taken not to stir the spot moistened by sulphuric acid with a rod before the addition of the bichromate, and not to expose the spot to a very strong light, which interferes with the chemical reactions. (*Lond. Med. Times and Gaz.*, June, 1857, p. 620.) It is probable that the process of dialysis might be advantageously applied to the separation of strychnia from the organic matters containing it, when brought to the liquid state. (See *Dialysis*, page 933.) Diluted acetic acid may be used for extracting the alkaloid with other soluble substances from the content of the stomach.

It is stated by Mr. C. W. Bingley that, if much tartar emetic be contained in a solution with a little strychnia, a pale-greenish colour is produced instead of the violet; and, in like manner, if chloride of antimony be present, the sulphuric acid and bichromate of potassa test fails altogether. (*Chem. Gaz.*, June 16, 1856, p. 229.) Mr. Richard Hagen, having been induced, by the assertion of Von Sicherer that this test fails when the strychnia is mixed with tartar emetic or other tartrates, or even tartaric acid, to investigate the subject, ascertained that this statement, as a general rule, is erroneous; for the reaction takes place with strychnia or its muriate, though mixed with 20 or 30 parts of tartrate of antimony; yet when *nitrate of strychnia* is used with 20 parts of the antimonial tartrate, the mass almost instantly acquires a green colour with the reagents mentioned. But even with nitrate of strychnia, the test succeeds if peroxide of lead is used instead of chromic acid as the oxidizing agent. (*Ibid.*, Oct. 15, 1857, p. 398.)

For a particular account of the results produced by the reaction of a large number of substances with strychnia, the reader is referred to a paper by Dr. T. G. Wormley, in the *Chemical News* for April 14th and 28th, 1860 (pp. 218 and 242). Among other trials made by him was that of the action of this alkaloid on frogs, proposed as a test by the late Dr. Marshall Hall. The poison was injected into the stomach of the animals through a pipette. A solution containing 1 per cent. of strychnia immediately produced rigidity and violent tetanic spasms, and death in 8 minutes. With 1 part of strychnia to 1000 of the menstruum, the spasmodic symptoms were induced in 3 or 4 minutes; with 1 in 10,000, in from 10 to 24 minutes; with 1 in 20,000, and 1 in 30,000, the symptoms were less unequivocal, though tetanic spasms were noticed in some of the animals.

Experiments by Mr. W. A. Guy on the effects of sulphuric and nitric acids on strychnia and many other alkaloids, published with tabulated results, show that in no one out of 66 proximate principles, chiefly alkaloids, was the same change of colour produced as in

pecially in connection with organic matter, so far modified or disguised the action of the test upon strychnia as to prevent the appearance of the characteristic colour; but subsequent and carefully conducted experiments, by the late Dr. Robert P. Thomas, satisfactorily determined that the conclusions in relation to the effects of morphia were erroneous, and that whether alone or associated with organic matters, in small or in large quantity, it does not prevent the operation of this colour-test if carefully applied. (*Am. Journ. of Med. Sci.*, Oct. 1861, p. 414; and April, 1862, p. 340.) Strychnia consists of carbon, hydrogen, nitrogen, and oxygen; but the proportion of its constituents is very differently given by different authors. Liebig states the composition to be $C_{44}H_{23}N_2O_4$; in the British Pharmacopœia, it is given as $C_{42}H_{22}N_2O_4$, which is the formula inferrible from the analysis of Gerhardt. (See *Am. Journ. of Pharm.*, March, 1859, p. 135.) The salts of strychnia are for the most part soluble and crystallizable. Their solution is decomposed by the alkalies and their carbonates, and by tannic, but not by gallic acid; and is not affected by the salts of sesquioxide of iron. They are precipitated by the solution of iodine in iodide of potassium, and the precipitate, though soluble in alcohol, is insoluble in the diluted acetic and muriatic acids of the U. S. Pharmacopœia. (Fairthorne, *Am. Journ. of Pharm.*, xxvii. 212.)*

Strychnia is apt to contain impurities, of which the chief, besides brucia, are colouring matter, and lime or magnesia. The two latter impurities are left behind when the adulterated alkaloid is incinerated in the open air. Pure strychnia leaves no ashes under these circumstances. Brucia is detected by the red colour which it yields with nitric acid. Neither this nor sulphuric acid colours strychnia; a test which serves to distinguish it from several other alkaloids.

Medical Properties and Uses, &c. The effects of strychnia upon the system are identical in character with those of nux vomica, and it is employed for the same purposes as a medicine. (See *Nux Vomica*, page 577.) It operates in the same way by whatever avenue it may enter into the circulation; but is said to act most powerfully when injected into the veins, or applied to a fresh wound. The blood of an animal under its influence produces similar effects in another, if transfused into its veins. There is no doubt that it is absorbed; as, after having been swallowed, it has been found in the urine, the blood, and the tissue of various organs. In overdoses it is a most violent poison. Pelletier and Caventou killed a dog in half a minute with one-sixth of a grain of the pure alkaloid. One grain or even less might prove fatal in the human subject. A case, however, is recorded in which recovery took place after seven grains had been swallowed; but the medicine was probably impure. (See *Am. Journ. of Med. Sci.*, N. S., xxx. 562.) Its most striking and characteristic effect, when taken in poisonous doses, is violent tonic spasms of the muscles, like those of tetanus, which sometimes continue after death. According to M. Duclos, the poisonous effects of

strychnia by concentrated sulphuric acid, followed by a crystal of bichromate of potassa. (See *Am. Journ. of Pharm.*, Nov. 1861, p. 517.) In the same number of the same journal (p. 527) is a paper by Mr. T. E. Jenkins, giving the result of experiments with sulphuric acid and bichromate of potassa on numerous alkaloids, all tending to prove the delicacy and certainty of this colour-test of strychnia. (*Note to the eleventh and twelfth editions.*)

* When an aqueous solution of sulphate of strychnia and nitrite of potassa is boiled, an effervescence takes place owing to the escape of nitrogen, and the solution becomes yellow. If ammonia be now added, a precipitate takes place, which has been found to consist of two new alkaloids, resulting from the oxidation of the strychnia in different degrees. One of these the discoverer, P. Schutzenberger, proposes to name *oxystrychnia*, and the other *binoxystrychnia*. (See *Am. Journ. of Pharm.*, March, 1859, p. 133.)

Methyl-strychnia. Methyl-brucia. These alkaloids are formed by replacing one of the eqs. of hydrogen in strychnia by methyl (C_2H_3), which is effected by acting on the alkaloids by iodide of methyl. A singular and, if verified, very important statement in relation to these modifications of strychnia and brucia, made by Stahlschmidt (*Ann. der Phys. und Chem.*), is that they are not poisonous. He gave to a rabbit five grains of methyl-strychnia, without any bad symptoms, though the same animal was afterwards killed in five minutes by one-twentieth of a grain of strychnia placed upon its tongue. The important practical inference is that iodide of methyl ought to be an antidote to strychnia. (See *Am. Journ of Pharm.*, May, 1860, p. 220.)—*Note to the twelfth edition.*

strychnia upon animals subside under the application of negative electricity, while they are aggravated by the positive. (See *Am. Journ. of Pharm.*, xvi. 154.) M. Boudet has found that chlorine water alternated with tartar emetic, so as to produce vomiting, obviates these effects in dogs. (*Arch. Gén.*, Fév. 1853, p. 222.) Kermes mineral has been recommended by M. Thorel as an antidote, being thought by him to form with strychnia an insoluble sulphuret, at the same time aiding any other emetic which may be administered for its expulsion. In cases of poisoning with strychnia he recommends fifteen grains of kermes, and one and a half grains of tartar emetic. MM. Bouchardat and Gobley state that, out of the body, the ioduretted iodide of potassium acts far more powerfully in producing an absolutely insoluble compound. (See *Am. Journ. of Pharm.*, xxiii. 84.) Tincture of iodine has the same effect, as proved by the experience of Mr. Young, and afterwards confirmed by Dr. H. W. Fuller, of London. (*Lancet*, March 21, 1868, p. 373.) But, though this fact establishes the impropriety of combining solutions of iodine and strychnia in prescriptions, yet it by no means justifies the inference drawn from it, that iodine might serve as an antidote to strychnia; and, indeed, the contrary has been proved by the experiments of Mr. S. Darby, who found that the precipitate of iodide of strychnia was highly poisonous to the lower animals, and that it is in fact not altogether insoluble in the gastric liquids, as it yielded decided bitterness to water digested with it for three hours at 90° F. (*Pharm. Journ.*, May, 1868, p. 535.) Animal charcoal has been employed with a view to absorb the poison; being thrown in by means of a stomach-tube. (*Lond. Med. Times and Gaz.*, April, 1855, p. 423.) Tannic acid, chlorine, and the tinctures of iodine and bromine are recommended as the best antidotes by Prof. Bellini. (See *Am. Journ. of Med. Sci.*, July, 1863, p. 276.) The indications are to evacuate the stomach, using at the same time any chemical antidote that may be at hand, and to relieve the spasms by opiates, ether, or other narcotics. Of the emetics sulphate of zinc would be among the most efficient; and powdered mustard has been highly recommended. They should be aided by the very free use of warm water. But it often happens that, before aid arrives, enough of the poison has been absorbed to produce death; so that vomiting, even aided by chemical antidotes, cannot be relied on. To relieve the spasm, besides *opium* and *ether*, *camphor* has been used with supposed success; and several cases are on record in which the inhalation of *chloroform* has not only afforded great relief, but appears to have been the means of saving life. Chloroform has been used also with seeming advantage by the stomach. In a case recorded by Dr. Dresbach, of Tiffin, Ohio, two drachms, swallowed by a patient alarmingly ill from the effects of three grains of strychnia, produced complete relief in less than fifteen minutes. (*Am. Journ. of Med. Sci.*, xix. 546; from *Western Lancet*, Feb. 1850.)* A case occurring at St. Louis, Missouri, is on record, in which a patient, who had taken six grains of strychnia, was, after having been vomited, apparently saved by the internal use of infusion of *tobacco*, administered by Drs. Byrne and O'Reilly. (*Ranking's Abstract*, No. 29, p. 287.) *Aconite* has been shown by experiments on dogs, performed by Dr. Woakes, to have a similar physiological antagonism with strychnia, and has been recommended in poisoning by this alkaloid, after evacuation of the stomach. (*British Med. Journ.*, Oct. 26, 1861.) *Cannabis Indica* has proved effectual in a case reported by Dr. S. A. M. Williams, of Chicago. The patient was an adult man, and had taken five grains of strychnia. Though most violently affected, he recovered under the use of tincture of cannabis, which was given in drachm doses, repeated at first in five minutes, then twice at intervals

* In a letter to the authors, from Dr. Wm. D. Barclay, dated Muscatine, Iowa, May 4th, 1863, the case of a robust young man is described, who, after taking four grains of strychnia, was seized with a most violent tetanic spasm, accompanied with intense suffering, and recovered under the use of chloroform, given both internally and by inhalation. It was necessary to keep him under the influence of the medicine for thirteen consecutive hours, during which two pounds of chloroform were consumed by inhalation. Two drops were given every five minutes, by the stomach, when the mouth could be opened. (*Note to the twelfth edition.*)

of ten minutes, and afterwards twice in fifteen minutes, with rapid improvement. Another similar dose was given in an hour and a half; and the remedy was afterwards repeated in alternation with camphor, as the symptoms seemed to require, till complete recovery at the end of 48 hours. (*Med. and Surg. Reporter*, Feb. 2, 1867; from *Med. Examiner.*) Besides the substances above mentioned, the *Calabar bean* has been proposed as a counter-poison to strychnia by Dr. Thos. P. Frazer, of Edinburgh, on the ground of its physiological properties, and *nitrite of amyl* by Dr. B. W. Richardson, of London, who, in experiments on frogs, found the poisonous influence of strychnia to be entirely controlled by exposing the animal under its influence to the vapour of that compound. (*B. and F. Medico-chir. Rev.*, Jan. 1865, pp. 264, 265.) Different persons are very differently susceptible to the action of strychnia, and some are powerfully affected by the smallest doses. Besides being more or less impure as kept in the shops, it cannot be relied on with certainty. Hence the necessity of great caution in prescribing it, and of carefully watching the patient during its use. The best plan is always to begin with very small doses, and gradually increase till its effects are observed. From one-sixteenth or even one-twenty-fourth to one-twelfth of a grain internally, and from an eighth to one-third of a grain externally, upon a blistered surface, may be employed at first; and afterwards increased if necessary. It is most conveniently administered in the form of pill. It may be given also in the saline state, which is produced by dissolving it in water acidulated with sulphuric, muriatic, nitric, or acetic acid. For its therapeutical applications, see *Nux Vomica* in *Part* I. Among the diseases in the treatment of which it has recently been introduced is epilepsy when attended with uterine disturbance. Mr. Walter Tyrrell gives the details of several cases of the kind in which it proved effective; and, though not disposed to consider it a specific, he has no hesitation in affirming that it is very beneficial in a large majority of cases. (*Med. Times and Gaz.*, April, 1868, p. 415.) It has been considerably employed of late in paralytic affections by the method of hypodermic injection. From the thirty-sixth to the twenty-fourth of a grain has been found to be generally well borne, though some sensitive nervous systems require much less. (Charles Hunter, *B. and F. Med.-chir. Rev.*, April, 1868, p. 446.) In a case of hemeralopia a cure has been effected by strychnia and opium combined; the dose of strychnia being at first one-twenty-fourth of a grain, which was gradually increased to an eighth. (Dr. W. H. Gardner, *Am. Journ. of Med. Sci.*, April, 1867, p. 556.) Strychnia has also been used with supposed advantage in cholera (*Med. Times and Gaz.*, Jan. 1867, p. 8); and Dr. C. Hanfield Jones has found it successful in hypochondriasis. (*Ibid.*, May, 1867, p. 626.) Dr. Isaac Hays, of Philadelphia, has found a solution of acetate of strychnia, dropped into the eye, to possess powers similar to those of the Calabar bean, in producing contraction of the pupil, and influencing the muscles of accommodation, and has been for several years in the habit of using it for this purpose. (*Am. Journ. of Med. Sci.*, July, 1863, p. 266.)

Off. Prep. Liquor Strychniæ, *Br.;* Strychniæ Sulphas, *U. S.* W.

STRYCHNIÆ SULPHAS. *U. S. Sulphate of Strychnia.*

"Take of Strychnia *a troyounce;* Diluted Sulphuric Acid *nine fluidrachms*, or *a sufficient quantity;* Distilled Water *a pint.* Mix the Strychnia with the Distilled Water, heat the mixture gently, and gradually add Diluted Sulphuric Acid until the alkaloid is neutralized and dissolved. Filter the solution, and evaporate with a moderate heat, so that crystals may form on cooling. Lastly, having drained the crystals, dry them rapidly on bibulous paper, and keep them in a well-stopped bottle." *U. S.*

This salt is in colourless prismatic crystals, efflorescent on exposure, inodorous, extremely bitter, freely soluble in water, sparingly soluble in alcohol, and insoluble in ether. It melts with a moderate heat, losing nearly 14 per cent. of water of crystallization, and by a strong heat is completely dissipated. The chief advantage of this preparation over strychnia is its solubility in water, by which it is better adapted to external use, as for application to blistered surfaces, or

for subcutaneous injection, should this at any time be deemed advisable, or as an ingredient in collyria. But even these advantages may be so easily gained by adding a few drops of an acid, the acetic for example, to strychnia, as much to diminish the value of this as a distinct officinal preparation. The dose is the same as that of the alkaloid itself.* W.

SUCCI. *Br.*

Juices.

Though introduced to professional notice by Mr. Squire, so long since as in the year 1835, and subsequently used by many practitioners, the Juices have now for the first time been made officinal, as a distinct class of preparations. They consist of the expressed juices of fresh plants, preserved by the addition of one-third of their bulk of alcohol. Considering the great inequality in strength, and of course uncertainty in operation of the fresh juices themselves, according to soil, climate, mode of cultivation, season, and age of the plant, it may be questioned whether they merit the prominence which has been given them in the British Pharmacopœia; unless, indeed, an exception may be made in the instance of the *Succus Conii*, which seems to be the most to be relied on of the preparations of hemlock. Only three of the Juices have been made officinal.

SUCCUS CONII. *Br. Juice of Hemlock.*

"Take of Fresh Leaves of Hemlock *seven pounds;* Rectified Spirit *a sufficiency*. Bruise the Hemlock in a stone mortar; press out the juice; and to every three measures of juice add one of the Spirit. Set aside for seven days, and filter. Keep it in a cool place." *Br.*

The albumen is probably coagulated under the influence of the alcohol; and hence the propriety of directing filtration. The dose of this preparation is from 30 to 90 minims.

Dr. John Harley, of London, in his experiments on the different preparations of

* *Arsenite of Strychnia* having been proposed as a remedy by Prof. Grimelli, of Modena, M. Chiappero, of Turin, undertook to prepare the salt. For this purpose he dissolved arsenious acid in water acidulated with muriatic acid, and neutralized the arsenious acid with strychnia. But, according to M. T. Cresoli, of Paris, the result was a mixture of arsenite and muriate of strychnia. The latter chemist prepares a pure arsenite of strychnia in the following manner. He takes 3·12 grammes of caustic potassa, 3·30 of arsenious acid, and 40·00 of distilled water. Having dissolved the potassa in the water, boiling-hot, he adds the arsenious acid, which is completely dissolved. He then dilutes 2·65 grammes of monohydrated sulphuric acid with 20 grammes of distilled water, and, having heated the mixture to ebullition, adds 12 grammes of pure crystallized strychnia, which is entirely dissolved. The two solutions being kept at about the temperature of 100° F., he pours the arsenical solution into that of strychnia. A grumous mass is produced, much of which, however, is dissolved by heat. The liquid being filtered boiling-hot from the undissolved mass, which consists almost exclusively of sulphate of potassa, the filtered liquid is evaporated nearly to dryness, and the residue dissolved in absolute alcohol, by which the sulphate of potassa is all left behind. The undissolved mass, after the first filtration, is repeatedly washed with alcohol; and the alcoholic solutions are mixed, concentrated, and set aside to crystallize. At the end of two days the arsenite separates in the form of cubic crystals.

Arsenite of strychnia is in white cubic crystals, containing water, which they lose in contact with the air, becoming almost efflorescent. They are completely decomposed by heat with an empyreumatic smell, and leave nothing but a black and porous charcoal. Toward the end of the vaporization, dense white vapours rise with the alliaceous smell of arsenic. The taste is bitter and metallic. Arsenite of strychnia is soluble in 35 parts of cold, and 10 of boiling water; is soluble also in alcohol, and less so in ether. Its formula is $C_{42}H_{22}N_2O_4,AsO_3$. Though scarcely yet employed, at least to any considerable extent, as a medicine, it would seem, from its constituents, to be likely to fulfil important indications, and has the advantage of a uniform composition. Consisting of two ingredients, each of which is perhaps scarcely inferior, as a remedy in intermittent fever, to any other except cinchona and its derivatives, it probably possesses strong antiperiodic powers, and might very properly be the subject of trial in any intermittent disease which proves rebellious to quinia; the prescriber, however, being always on his guard against its poisonous action. Its commencing dose should not be larger than the smallest dose of strychnia. (*Journ. de Pharm.*, 4e sér., i. 343.)—*Note to the thirteenth edition.*

conium, found the juice among the most efficient. When heated with a little caustic potassa, it gave out suffocating fumes of conia; and one fluidounce of it was ascertained to contain 0·42 grains of the pure alkaloid. From two fluidrachms of it he observed in his own person no observable effect. Three fluidrachms caused some defect of muscular power with a slight giddiness, which passed off in two hours and a half. From five and a half fluidrachms, he experienced, in 45 minutes, slight giddiness from defect of adjusting power in the eye, which had much increased at the end of an hour, and was attended with wide dilatation of the pupil, and muscular lethargy, and soon afterwards weakness of the limbs, squeamishness, and faintness like that caused by tobacco, coldness, paleness, tottering, and pulse at 68. The mind was perfectly clear, but he seemed heavy and as if "well-nigh asleep." There seemed to be a direct diminution of power in all the motor nerves, and the third pair seemed almost paralyzed. In two hours and three-quarters the pulse was at 56; but the paralytic effect had lessened; and in one hour more all the symptoms had disappeared. (See *Am. Journ. of Pharm.*, July, 1867, p. 363.) From the foregoing statements it may be inferred that, in the administration of this preparation, the dose should be gradually increased till some effect is experienced, and, to maintain the effect, should be repeated every two or three hours. W.

SUCCUS SCOPARII. *Br. Juice of Broom.*

"Take of Fresh Broom Tops *seven pounds;* Rectified Spirit *a sufficiency.* Bruise the Broom Tops in a stone mortar; press out the juice; and to every three measures of juice add one of the Spirit. Set aside for seven days, and filter. Keep it in a cool place." *Br.*

The dose of this preparation as a diuretic is from 30 minims to a fluidrachm. In large doses it would be apt to disturb the stomach and bowels. It is more appropriately used as an adjuvant to other diuretics than alone. W.

SUCCUS TARAXACI. *Br. Juice of Dandelion.*

"Take of Fresh Dandelion Root *seven pounds*; Rectified Spirit *a sufficiency.* Bruise the Dandelion Root in a stone mortar; press out the juice; and to every three measures of juice add one of the Spirit. Set aside for seven days, and filter. Keep it in a cool place." *Br.*

The dose of this juice is from two fluidrachms to half a fluidounce.* W.

* *Preserved Juice of Taraxacum.* Mr. Donovan proposes the following plan, by which the juice of taraxacum may be obtained and preserved throughout the year, with nearly all its native efficiency. The whole herb, immediately after collection, is to be washed, bruised, and expressed; and the residue, having been mixed with as much water at 200° as will bring it to the consistence of a pulp, is to be allowed to stand for two hours, and then again expressed. The liquids thus obtained are to be mixed, and very slowly evaporated, in a wide earthen vessel, and with constant agitation, to one-half. The salts are thus obtained, though with little of the bitter principle. To supply this, a quantity of the roots equal to the weight of the herb first employed, is to be bruised and expressed. The resulting juice, which is in small quantity and bitter, is to be set aside; while the residual marc is to be mixed with the concentrated juice already prepared, previously brought to a boiling heat. When cold, the mixture is to be strongly expressed, and the liquor obtained to be mixed with one-sixth of its measure of alcohol. The liquor is then to be poured into quart bottles, but so as not to fill them. These are to be immersed in a vessel containing water as high as the liquid within them, and placed over a fire; the water is to be slowly heated to 180°; the bottles are to be withdrawn; and the reserved juice of the root is to be added to each in equal quantities. The space at first left in the bottles should be such that, after the addition of the juice, and the driving in of the cork, as little as possible should remain. The corks, being now cut off close to the glass, are to be covered with hard sealing-wax; and the bottles set by, inverted, in a cool place. The alcohol used is alone insufficient for the preservation of the juice; and hence the necessity of heating the bottles, and sealing them when quite full, according to *Appert's process.* Each ounce will contain about a drachm of the alcohol. (See *Am. Journ. of Pharm.*, xxiv. 65.)

Professor Procter proposes the following plan. Of the fresh roots collected in September or October, twenty pounds avoirdupois are to be sliced transversely, reduced to a pulpy mass by grinding or contusion, then thoroughly incorporated with four pints of alcohol of 0·835, and set aside in stoneware jars. After a week, or a longer time, the pulpy mass is to be subjected to strong pressure, and the liquid filtered and bottled for use. Even after six months the pulp thus treated preserves the sensible properties of the dandelion

SULPHUR.

Preparations of Sulphur.

SULPHUR PRÆCIPITATUM. *U. S., Br.* Lac Sulphuris. *Precipitated Sulphur. Milk of Sulphur.*

"Take of Sublimed Sulphur *twelve troyounces;* Lime *eighteen troyounces;* Muriatic Acid, Water, each, *a sufficient quantity.* Pour sufficient Water on the Lime to slake it, and, having mixed the Sulphur with it, add fifteen pints of Water to the mixture; then boil for two hours, occasionally adding Water to preserve the same measure, and filter. Dilute the filtered liquid with an equal bulk of Water, and drop into it Muriatic Acid so long as a precipitate is produced. Lastly, wash the Precipitated Sulphur repeatedly with Water until the washings are nearly tasteless, and dry it." *U. S.*

"Take of Sublimed Sulphur *five ounces* [avoirdupois]; Slaked Lime *three ounces* [avoird.]; Hydrochloric Acid *eight fluidounces*, or *a sufficiency;* Distilled Water *a sufficiency.* Heat the Sulphur and Lime, previously well mixed, in a pint [Imperial measure] of the Water, stirring diligently with a wooden spatula; boil for fifteen minutes, and filter. Boil the residue again in half a pint [Imp. meas.] of the Water, and filter. Let the united filtrates cool, dilute with two pints [Imp. meas.] of the Water, and, in an open place or under a chimney, add in successive quantities the Hydrochloric Acid previously diluted with a pint [Imp. meas.] of the Water, until effervescence ceases and the mixture acquires an acid reaction. Allow the precipitate to settle, decant off the supernatant liquid, pour on fresh Distilled Water, and continue the purification by affusion of Distilled Water and subsidence, until the fluid ceases to have an acid reaction and to precipitate with oxalate of ammonia. Collect the precipitated sulphur on a calico filter, wash it once with Distilled Water, and dry it at a temperature not exceeding 120°." *Br.*

In the U. S. process three eqs. of lime react with six of sulphur, so as to form two eqs. of bisulphuret of calcium, and one of hyposulphite of lime ($3CaO$ and $6S = 2CaS_2$ and CaO,S_2O_2). On the addition of the muriatic acid, six eqs. of sulphur are precipitated (four from the two eqs. of bisulphuret of calcium and two from the one eq. of hyposulphite of lime), and the calcium and oxygen unite with the muriatic acid, so as to form chloride of calcium and water. This rationale is not exactly applicable to the British process, in which the proportion of the sulphur to the lime employed is much greater than in that of the U. S. Pharmacopœia. The muriatic acid is the most eligible precipitant for the sulphur; as it gives rise to chloride of calcium, which is a very soluble salt, and easily washed away. Sulphuric acid is wholly inadmissible; as it generates sulphate of lime, which, from its sparing solubility, becomes necessarily intermingled with the precipitated sulphur. According to Schweitzer, the best material from which to precipitate the sulphur is the sulphuret of potassium, formed by boiling sulphur with caustic potassa. Dr. Otto, of Brunswick, finds that sulphuret of potassium is apt to contain sulphuret of copper, and therefore prefers sulphuret of calcium. (*Pharm. Cent. Blatt*, Jan. 1845.)

Properties, &c. Precipitated sulphur is in friable lumps, of a white colour, with a pale yellowish-green tint, and consisting of finely divided particles slightly cohering. It is entirely dissipated by heat. Water boiled upon it should not redden litmus. When recently prepared, it is devoid of taste, but possesses a peculiar smell. When long exposed, in a moist state, to the air, it becomes strongly contaminated with sulphuric acid. From its colour it was formerly called *lac sulphuris*, or *milk of sulphur*. It is insoluble in water, but dissolves in a boiling solution of caustic potassa, and in oil of turpentine by the aid of heat.

in a marked degree. Should the alcohol in the expressed liquor be objected to, it may be partially removed by a gentle evaporation by means of a water-bath until the bulk of the juice has been diminished one-sixth, and then adding eight ounces of sugar for every pint. (*Ibid.*, xxv. 408.)—*Note to the tenth edition.*

When of a brilliant white colour, the presence of sulphate of lime may be suspected; in which case the preparation will not be wholly volatilized by heat. If pure it communicates a harsh feel when rubbed between the fingers, owing to the friction of the crystalline particles. (*Dr. Bridges.*) We have seen a sample of so-called precipitate of sulphur, which consisted almost entirely of sulphate of lime. Precipitated sulphur differs from sublimed sulphur in being in a state of more minute division, and in presenting, after fusion, a softer and less brittle mass. Its peculiarities are supposed to depend upon the presence of water, which, however, is found in too small a quantity to constitute a regular *hydrate*. According to Rose, its white colour is occasioned by the presence of a small proportion of bisulphuretted hydrogen. Soubeiran states that it always contains some sulphuretted hydrogen, which causes it to differ as a therapeutic agent from sublimed sulphur.

Medical Properties and Uses. Precipitated sulphur possesses similar medical properties to those of sublimed sulphur. It is the form of sulphur used by Dr. Fuller, of London, as an external application in sciatica and chronic rheumatism. (See *Sulphur*, Part I.) Its state of extreme division renders it more readily suspended in liquids; but its liability to become acid by keeping is an objection to it. It is sometimes selected for forming ointments, which have the advantage of being of a lighter colour than when made with sublimed sulphur. The dose is from one to three drachms. B.

SULPHURIS IODIDUM. *U. S., Br. Iodide of Sulphur. Bisulphuret of Iodine.*

"Take of Iodine *four troyounces;* Sublimed Sulphur *a troyounce.* Rub them together until they are thoroughly mixed. Introduce the mixture into a flask, close the orifice loosely, and apply a gentle heat so as to darken the mass without melting it. When the colour has become uniformly dark throughout, increase the heat so as to produce liquefaction. Then incline the flask in different directions, in order to return into the liquid any portions of Iodine which may have been condensed on the inner surface of the vessel. Lastly, withdraw the heat, and, when the liquid has congealed, remove the mass by breaking the flask, reduce it to pieces, and keep these in a well-stopped bottle." *U. S.*

The British process is precisely the same as the above, which was derived from the French Codex. Though formerly officinal with the London and Dublin Colleges, it was omitted in the first British Pharmacopœia, to be resumed in the present. It simply effects a combination of the two ingredients.

Properties, &c. Iodide of sulphur has a grayish-black colour, and radiated crystalline appearance like that of sulphuret of antimony. Its smell resembles that of iodine, and it stains the cuticle in a similar manner. It dissolves in sixty parts of glycerin, forming a solution which would probably prove useful, in some cases, as a substitute for the ointment of this iodide. It is rapidly decomposed, when in a state of powder, upon the addition of several of the volatile oils, violet vapours of iodine being evolved, and the smell of sulphur perceived. (*Dr. G. W. Patterson.*) It is entirely volatilized by heat, and by continued boiling with water is wholly decomposed, iodine escaping with the steam, and sulphur being left nearly pure. The proportion of sulphur thus obtained is about 20 per cent. (*Lond. Pharm.*) This result shows that the compound is a bisulphuret. Iodide of sulphur has been very usefully employed as an external remedy in various skin diseases, such as tinea capitis, lupus, lepra, &c., applied in the form of ointment. (See *Unguentum Sulphuris Iodidi.*) It has been used internally, associated with iodide of potassium and senna, in the form of a syrup, in scrofulous and cutaneous diseases. (*E. Levrat.*) This syrup contains ioduretted iodide of potassium, and free sulphur, in consequence of a reaction which takes place between the two iodides. In a case of glanders in the human subject, which terminated in recovery under the care of M. Bourdon, of Paris, the iodide of sulphur was used internally, and was thought to have exercised a favourable influence. (*Ann. de Thérap.*, 1858, p. 239.)

Off. Prep. Unguentum Sulphuris Iodidi. B.

SUPPOSITORIA. *Br.*

Suppositories.

As a class of officinal preparations, suppositories have been introduced into the British Pharmacopœia; and they would seem to have a claim to this position quite as strong as the *Enemata*, which have long been officinally recognised. Indeed, provision has been made in the U. S. Pharmacopœia for such a class, by the introduction into the Materia Medica Catalogue of the *butter of cacao* (Oleum Theobromæ), which, beyond all other substances, is peculiarly calculated for their preparation. Suppositories are solid bodies intended to be introduced into the rectum, with a view either of evacuating the bowels by irritating the mucous membrane of the rectum, or of producing a specific effect on the neighbouring parts, or on the system at large. They fulfil the same indications as enemata, and are sometimes preferable from the facility of their application, and, when the object is to produce the peculiar effect of a medicine, from the smallness of their bulk, which facilitates retention. Their form may be cylindrical, conical, or spherical; the last being preferable when the bulk is small. They should be of such a consistence as to retain their shape, but so soft as to incur no risk of wounding the rectum. For laxative purposes the suppository may be from one to three inches long, and about as thick as a common candle; with a view to the specific effects of medicines, it should be considerably smaller, as in this case it is important that the medicines should be retained, and the irritative influence of distention avoided. Soap is not unfrequently employed in this way as a laxative. A piece of solidified molasses (molasses candy) is sometimes preferred. To increase the purgative effect, and at the same time act on the uterine function, aloes may be added to the soap. Mr. A. B. Taylor, of Philadelphia, some years since called attention to cacao butter, already familiar to French pharmacy, as the best excipient for solids administered by the rectum, having more exactly the requisite degree of consistence and fusibility than any combination of suet, spermaceti, wax, &c., that could be employed. (*Am. Journ. of Pharm.*, July, 1852, p. 211.) Experience has shown that the consistence of cacao butter for this purpose may be improved by incorporating it with a little wax, from one-fifth to one-eighth of its weight. This may be done by melting the two together at the time of preparing the suppositories; or the mixture may be kept ready-made on hand. In preparing the suppository, the excipient should be liquefied by a gentle heat, the medicine then incorporated with it, and the mixture poured into suitable moulds to harden. A convenient weight for each suppository is about twenty-five grains; but this may be much lessened or increased as circumstances may seem to demand.* The weight at present directed by the Br. Pharmacopœia is fifteen grains, and this appears to be in conformity with the recommendation of Mr. H. B. Brady, whose remarks on the subject of medicated suppositories, contained in the *Pharmaceutical Journal* (May, 1866, p. 544, and Jan. 1868, p. 321), are well worthy of being consulted. It has been recommended to form

* It has been customary to give shape to the suppository by pouring the materal previously melted into small paper moulds of a conical form, which may readily be made by rolling up an oblong slip of strong glazed paper with the fingers. The hollow cones may be an inch or more in length, and about half an inch in diameter at the base. A more convenient method, however, is to cast the suppository in metallic moulds. Mr. A. B. Taylor, who has paid special attention to the subject, recommends that their shape, instead of being strictly conical, should be somewhat incurved towards the base, where there may be a small cylindrical projection for the purpose of fitting into the end of a very convenient instrument, invented by him for the introduction of the suppository into the rectum. This instrument, which he calls a *Suppositer*, consists of a slender handle a few inches long, with a ring at one end for the finger, and an expansion at the other, having a cavity for the reception of the cylindrical base of the suppository. The metallic mould should be very cold at the time of introducing the melted mixture, so as quickly to solidify it, and thus prevent the suspended medicine from sinking to the bottom, and becoming unequally distributed. (*Am. Journ. of Pharm.*, May, 1861, p. 202.)—*Note to the twelfth edition.*

the excipient into the required shape, and then, while it is still soft, make an excavation from the base upward, into which the medicine may be introduced, and afterwards enclosed by a little of the cacao butter. But as one of the objects of the excipient is an equable diffusion of the medicine to prevent irritation, this method would be altogether inapplicable to substances in any degree locally irritant. Opium, or some one of its preparations, is very advantageously administered in the form of a suppository, in cases of irritation of the rectum, urinary passages, or genital apparatus. The other narcotics may be used in the same way; and indeed any other medicine, in reference to its effects on the system, provided the quantity be not too large, and the local effects not too irritant. Tannic acid or other astringent substance may also be very appropriately employed in this way in cases of prolapsus, or other affection depending on relaxation of the rectum or anus. The dose may in general be three times that of the medicine given by the mouth.* W.

SUPPOSITORIA ACIDI TANNICI. *Br.* *Tannic Acid Suppositories. Tannin Suppositories.*

"Take of Tannic Acid *thirty-six grains;* Benzoated Lard *forty-four grains;* White Wax *ten grains;* Oil of Theobroma *ninety grains.* Melt the Wax and Oil of Theobroma with a gentle heat, then add the Tannic Acid and Benzoated Lard previously rubbed together in a mortar, and mix all the ingredients thoroughly. Pour the mixture while it is fluid into suitable moulds of the capacity of fifteen grains; or the fluid mixture may be allowed to cool, and then be divided into twelve equal parts, each of which shall be made into a conical or other convenient form for a *suppository.*" *Br.*

The British Pharmacopœia has increased the number of its suppositories from two, as it was in the first edition, to four; but, even thus doubled, they are so few as to justify the supposition that the intention of its framers was not to limit the number employed so narrowly, but to present a model form, after which others might be prepared. It is certain that a good choice of the active ingredients has been made; for, omitting the mere laxative suppository, few are perhaps more frequently used than those of tannic acid, some one of the preparations of opium, and the acetate of lead. A change has been very judiciously made, in the excipients, from the glycerin of the former Pharmacopœia to the cacao butter of the present; as the latter is of a consistence admirably adapting it to the purpose, requiring the addition of but a small proportion of wax. The benzoated lard, which is now first used, is added with the view of preventing rancidity. The weight of each suppository is about 15 grains, and the quantity of tannic acid in each 3 grains. The remedy is especially applicable to piles and prolapsus of the rectum from relaxation. W.

SUPPOSITORIA HYDRARGYRI. *Br.* *Mercurial Suppositories.*

The Pharmacopœia takes of Ointment of Mercury *sixty grains;* Benzoated Lard and White Wax, of each, *twenty grains;* and Oil of Theobroma *eighty grains;* and, having directed the Benzoated Lard, Wax, and Oil of Theobroma, previously melted with a gentle heat, to be thoroughly mixed with the Ointment of Mercury, without the further application of heat, completes the process precisely in the manner directed for the Tannic Acid Suppositories.

* *Medicated Pessaries*, which have been brought into notice of late years, chiefly through the recommendation of Sir J. Y. Simpson, of Edinburgh, so closely resemble suppositories, so far as pharmacy is concerned, as to justify an allusion to them in this place. All that has been said of the materials out of which suppositories are made, and the mode of preparing them, is equally applicable to medicated pessaries. The latter, however, are considerably larger, generally weighing one or two drachms. They differ also from suppositories in the purposes to which they are applied; being used for local effect, in allaying pain, checking discharge, acting as alterative to contiguous parts, &c., while the latter preparations, though used also as topical agents, are very often prescribed with a view to their systemic effects. On the subject of both of these classes of preparations, the pharmaceutical reader is referred to an article in the *Am. Journ. of Pharm.* (May, 1868, p. 223), by Mr. J. B. Moore, of Philadelphia, for useful practical suggestions, which our limited space will not permit us to introduce here. (*Note to the thirteenth edition.*)

The quantity of the mercurial contained in each suppository is five grains. This is not a common method of employing mercury for affecting the system; but might be advantageously resorted to in cases of great irritability of stomach, and where objection exists to the use of the ointment by friction to the skin. When this object is aimed at, the suppository might be repeated twice or three times in 24 hours. W.

SUPPOSITORIA MORPHIÆ. *Br. Morphia Suppositories.*

The Pharmacopœia takes of Hydrochlorate of Morphia *six grains;* Benzoated Lard *sixty-four grains;* White Wax *twenty grains;* and Oil of Theobroma *ninety grains;* and, having melted the Wax and Oil with a gentle heat, added the Hydrochlorate of Morphia and Benzoated Lard previously rubbed together in a mortar, and mixed all the ingredients thoroughly, completes the process in the same manner as that for the Tannic Acid Suppositories.

This is an excellent remedy in strangury, tenesmus, and other cases of irritation in the lower bowels and urinary passages. It may also be used to control vomiting, and to produce the general effects of opium on the system. Each suppository contains half a grain of muriate of morphia, which is about the quantity required to produce the full effects of morphia on the system in the adult. W.

SUPPOSITORIA PLUMBI COMPOSITA. *Br. Compound Lead Suppositories.*

The Pharmacopœia takes of Acetate of Lead *thirty-six grains;* Opium, in powder, *twelve grains;* Benzoated Lead *forty-two grains;* White Wax *ten grains;* and Oil of Theobroma *eighty grains;* and, having melted the Wax and Oil with a gentle heat, added the other ingredients previously rubbed together in a mortar, and mixed the whole thoroughly, completes the process in the same manner as that for the Tannic Acid Suppositories.

Each suppository contains three grains of the acetate of lead, and one grain of opium, and is an excellent remedy in some cases of diarrhœa, dysenteric irritation of the rectum, piles, and hemorrhage. W.

SYRUPI.

Syrups.

Syrups are concentrated solutions of sugar in watery fluids, either with or without medicinal impregnation. When the solution is made with pure water, it is named *syrup* or *simple syrup*, when with water charged with one or more medicinal agents, it is called in general terms a *medicated syrup*, and receives its particular designation from the substance or substances added.

Medicated syrups are usually prepared by incorporating sugar with vegetable infusions, decoctions, expressed juices, fermented liquors, or simple aqueous solutions. When the active matter of the vegetable is not readily soluble in water, is associated with soluble matter which it is desirable to avoid, or is volatilized or decomposed by a heat of 212°, it is sometimes extracted by diluted alcohol, the spirituous ingredient of which is subsequently driven off. Medicated syrups are also occasionally prepared by adding a tincture to simple syrup, and evaporating the alcohol. Another and better mode of effecting the same object, when aromatic or other volatile substances are concerned, is to mix the tincture with sugar in coarse powder, expose the mixture to a very gentle heat or in the sun till the alcohol has evaporated, and then prepare the syrup from the impregnated sugar by dissolving it in the requisite proportion of water. Since the introduction into use of the process of percolation, or filtration by displacement, it has been applied very advantageously to the preparation of various syrups, especially those made from vegetables of which the active principle is injured or dissipated by decoction. But, unless the operator be at once skilful and careful, there will be danger of imperfectly extracting the active matters, and thus mak-

ing a feeble preparation. One important practical rule is, when the liquid obtained by percolation requires concentration, to set aside the first portions of filtered liquor, which are usually strongly impregnated, and to subject only the subsequent weaker portions to evaporation. For the mode of properly conducting this process the reader is referred to *pages* 931 and 942.

The quality and quantity of the sugar employed are points of importance. Refined sugar should always be preferred, as it often saves the necessity of clarification, and makes a clearer and better flavoured syrup than the impure kinds. The U. S. Pharmacopœia simply directs sugar, but explains that it is the purified or refined sugar which is indicated by that term. In relation to the quantity of sugar, if in too small proportion, fermentation is apt to occur; if too abundant, crystallization. The proper proportion is about two parts to one of the liquid. A somewhat smaller quantity will answer, where an acid, such as lemon juice or vinegar, is used.

As it is desirable, in many instances, that the active matters should be in as concentrated a state as possible in the syrup, it is often necessary to evaporate a large proportion of the watery fluid in which they are dissolved. This may be done either before the addition of the sugar or afterwards. In either case, care is requisite not to apply a heat too great or too long continued, lest the active principles should be injured. When these are very volatile or easily decomposed by heat, it is expedient to dispense with concentration altogether. Some substances which are volatilized or decomposed at the temperature of boiling water remain fixed and unaltered at that which is necessary for the evaporation of alcohol. These, as before observed, may be dissolved in diluted alcohol, and the concentration effected by evaporating the spirituous part of the solvent. Independently of the injury which the medicinal ingredient of the syrup may sustain, the syrup itself is apt to become brown by a long-continued application of heat, even when the degree is not excessive. It is recommended, therefore, that syrups which admit of concentration should be boiled briskly over a lively fire, so as to accomplish the object as quickly as possible. It is important to be able to ascertain positively when they have attained the due consistence. An operator skilled in their preparation can judge with sufficient accuracy by various familiar signs; such as the slowness with which the parts of a drop of syrup coalesce, when previously separated by the edge of a blunt instrument; and the receding of the last portion of each drop, when the syrup, after being cooled, is poured out drop by drop. A pellicle forming upon the surface of the syrup when it cools, indicates that it has been too much boiled. But these signs are not to be relied on, except by those who have acquired much experience. The easiest method of ascertaining the proper point of concentration is by the use of that variety of Baumé's hydrometer called a *saccharometer;* an instrument almost indispensable to the apothecary. This should stand at 30° in boiling syrup (30½ in hot weather), and at 35° in the syrup when it is cool. Another very accurate, though less ready method, is to ascertain the sp. gr. by weighing a portion of the liquid. Syrup when boiling should have a sp. gr. of about 1·261; when cold, of about 1·319. Thomson and Duncan are mistaken in giving the proper sp. gr. of cold syrup as 1·385. We found that of a specimen of simple syrup, made with two pounds and a half of sugar to a pint of water, as directed in former editions of the U. S. Pharmacopœia, to be 1·326 at 68° F.; and this consistence is rather too great for practical convenience in cold weather. In the syrup now officinal it is only 1·317 at 60°, which is an improvement. A third method of ascertaining the proper point of concentration is by the thermometer, which, in boiling syrup of the proper consistence, stands at 221° F. This indication is founded on the fact, that the boiling point of syrup rises with the increase of its density.

When carefully prepared with the best double refined sugar, syrups usually require no other clarification than to remove any scum which may rise to their surface upon standing, and to pour them off from any dregs which may subside. But, as the sugar employed is seldom free from impurities, it may be best, as a

general rule, to remove the scum as it rises during the heating process, and to strain them while hot through muslin or flannel. Should they at any time want the due degree of clearness, they may be filtered through flannel, or, when not likely to be injured by the treatment, may be clarified by means of the white of eggs or animal charcoal, as mentioned under the head of *Syrupus*. But the active vegetable principles are so apt to be absorbed by the charcoal along with impurities, that this agent should be used with caution.

The medicated syrups are liable to undergo various alterations, according to their nature and mode of preparation. The acid syrups, when too much boiled, often let fall a copious white deposit, which is a saccharine matter analogous to the sugar of grapes, produced by the reaction of the acid upon the sugar. Even at ordinary temperatures, acids slowly convert common sugar into the sugar of grapes, which being less soluble than the former, is gradually deposited in the form of crystalline grains. Syrups containing too little sugar are apt to pass into the vinous fermentation, in consequence of the presence of matters which act as a ferment. Those which contain too much deposit a portion in the crystalline state; and the crystals, attracting the sugar remaining in solution, gradually weaken the syrup, and render it liable to the same change as when originally made with too little sugar. The want of a due proportion of saccharine matter frequently also gives rise to mouldiness, when air has access to the syrup. It is said that syrups, enclosed while they are still hot in bottles, are apt to ferment; because the watery vapour, rising to the surface and there condensing, diminishes the proportion of sugar, so as to produce a commencement of chemical action, which gradually extends through the whole mass; but, if the bottles are well shaken, this result is obviated; and the syrups will generally keep better when thus treated. When syrups undergo the vinous fermentation, they become covered at the surface with froth, produced by the disengagement of carbonic acid, and acquire a vinous odour from the presence of alcohol; while their consistence is diminished by the loss of a portion of the sugar, which has been converted into that liquid. When the quantity of alcohol has increased to a certain point, the fermentation ceases, or goes on more slowly, owing to the preservative influence of that principle; and, as the active ingredient of the syrup has frequently undergone no material change, the preparation may often be recovered by boiling so as to drive off the alcohol and carbonic acid, and concentrate the liquid sufficiently. A syrup thus revived is less liable afterwards to undergo change, because the principles which acted as ferments have been diminished or consumed. It is obvious that syrups which depend for their virtues upon a volatile ingredient, or one readily changeable by heat, cannot be restored to their original condition.

At best syrups are too apt to change, and various measures have been proposed for their preservation. According to Dr. Macculloch, the addition of a little sulphate of potassa, or chlorate of potassa which is tasteless, prevents their fermentation. M. Chereau has found sugar of milk effectual to the same end, in the instance of the syrup of poppies; and it may prove useful in others. The proportion employed by him is 32 parts of sugar of milk to 1000 of syrup. Mr. E. Durand has found that 1·3 per cent. of Hoffmann's anodyne has the effect of completely arresting or preventing fermentation, probably through the agency chiefly of the oil of wine contained in it. (*Am. Journ. of Pharm.*, xiii. 185.) But the best plan is to make small quantities of syrups at a time, and to keep them, unless when wanted for immediate use, in bottles quite full and well stopped, which should be put in the cellar or other cool place.

The Syrups, formerly officinal, which have been omitted in the present U. S. and Br. Pharmacopœias, are *Syrupus Aceti*, Ed., *Syrupus Althææ*, Lond., Ed., *Syrupus Cocci*, Lond., *Syrupus Croci*, Lond., Ed., Dub., *Syrupus Rosæ* (*Centifoliæ*), Lond., Ed., *Syrupus Sarzæ*, Lond., Ed., and *Syrupus Violæ*, Ed. W.

SYRUPUS. *U. S.*, *Br.* SYRUPUS SIMPLEX. *Syrup. Simple Syrup.*

"Take of Sugar [refined], in coarse powder, *thirty-six troyounces;* Distilled Water *a sufficient quantity.* Dissolve the Sugar, with the aid of heat, in twenty

fluidounces of Distilled Water, raise the temperature to the boiling point, and strain the solution while hot. Then add sufficient Distilled Water, through the strainer, to make the syrup measure two pints and twelve fluidounces, or weigh fifty-five troyounces. Lastly, incorporate the Water, added through the strainer, with the solution. Syrup, thus prepared, has the specific gravity 1·317." *U. S.*

"Take of Refined Sugar *five pounds* [avoirdupois]; Distilled Water *two pints* [Imperial measure]. Dissolve the Sugar in the Water with the aid of heat; and add, after cooling, as much Distilled Water as may be necessary to make the weight of the product seven pounds and a half [avoird.]. The sp. gr. should be 1·330." *Br.*

This syrup, when properly prepared, is inodorous, of a sweet taste without peculiar flavour, thick, viscid, nearly colourless, and perfectly transparent. If somewhat turbid, as it is apt to be when made with sugar not well refined, it may be clarified by beating the white of an egg to a froth with three or four ounces of water, mixing this with the syrup, boiling the mixture for a short time that the albumen may coagulate, and taking off the scum which rises to the surface, or separating it by filtration through paper or flannel. Two gallons of the syrup may be thus clarified. Any colour and peculiar flavour which it may possess may be removed by treating it, at the same time, with a small proportion (about 5 per cent.) of animal charcoal.

The white of egg is beaten to a froth in order that, when it coagulates, it may be rendered by the air which it contains specifically lighter than the syrup, and thus rise to the surface. If not thus treated, it floats, when coagulated, in the syrup, or sinks to the bottom. Now it is obvious that, if the syrup and albumen be heated together, the latter must be deprived of a portion of the air which it contains before the point of coagulation is attained, and thus become less disposed to rise to the surface. Guibourt, therefore, recommends that it should not be added till the syrup is boiling hot, and should then be poured in from a height, in order to increase the quantity of air entangled in it.

M. Salles, an apothecary of Clermont-Ferrand, in France, recommends that syrups which require clarification should be treated in the following manner. Allow the liquor with which the syrup is to be prepared, without previously decanting or filtering it, to become quite cold; then mix with it the white of eggs unbeaten, in the proportion of one egg for every five or six pounds (avoirdupois) of sugar employed; and, having added the sugar or honey, boil the whole for half an hour, or until a portion of the syrup upon cooling exhibits flocculi of albumen floating in a transparent medium. During the ebullition care must be taken to agitate the syrup in such a manner as to prevent the formation of foam upon its surface. When allowed to cool, the coagulated albumen with the impurities subsides, and the clear syrup floats above, and may be drawn off or decanted. In this process the albumen sinks, because not incorporated with air. M. Salles calls it clarification *per descensum*, and states that it is applicable to all syrups of a density below 30° Baumé at the boiling point. (*Journ. de Pharm.*, xxiv 490.)

From the observations of M. Maumene, it appears that a solution of pure cane sugar, when long kept, undergoes a molecular change analogous to that produced by the reaction of weak acids; the saccharine liquid becoming brown when boiled with potassa. But, as this phenomenon is exhibited alike by uncrystallizable sugar and by glucose, the experiment does not determine which of those forms of saccharine matter has been produced. (*Comptes Rendus*, xxxix. 914.) Prof. Procter has observed a similar change in simple syrup which had been kept in his cabinet for six years. (*Am. Journ. of Pharm.*, xxvii. 430.)

M. Schaeuffèle, having noticed, on one occasion, in the preparation of simple syrup, that the foam exhibited a singular blue colour, while a part of the cane sugar was rapidly transformed into the uncrystallizable variety, made investigations as to the cause of the phenomenon, and was led to the conclusion that it was the presence of indigo in the loaves of sugar, introduced with the view of giving brilliance to their whiteness; but M. Gaultier de Claubry is of the opinion

that the blueness might be owing to some derivative of anilin, and that the use of such a syrup might be hazardous. (*Journ. de Pharm.*, 4e sér., ii. 161.)

Syrup is very useful in the formation of pills and mixtures, and in various other pharmaceutical operations in which sugar in solution is required.

The U. S. syrup has the sp. gr. 1·317, which is as near as may be the true standard in our climate. That of the Br. syrup is 1·330, probably adapted to the climate of Great Britain, which is not so cold in winter as ours, at least in the Northern and Middle States.

Pharm. Uses. In preparing Pilulæ Aloës et Myrrhæ, *U. S.;* Pil. Cambogiæ Composita, *Br.;* Pil. Galbani Comp., *U. S.;* Pil. Scillæ Comp., *U. S.*

Off. Prep. Confectio Opii, *Br.;* Confectio Scammonii, *Br.;* Mistura Creasoti, *Br.;* Mistura Cretæ, *Br.;* Pilula Cambogiæ Composita, *Br.;* Pilulæ Ferri Carbonatis, *U. S.;* Pilulæ Ferri Compositæ, *U. S.;* Syrupus Acidi Citrici, *U. S.;* Syrupus Aurantii, *Br.;* Syrupus Ferri Iodidi, *U. S.;* Syrupus Ipecacuanhæ, *U. S.;* Syrupus Lactucarii, *U. S.;* Syrupus Rhei, *U. S.;* Syrupus Rhei Aromaticus, *U. S.;* Syrupus Rubi, *U. S.;* Syrupus Zingiberis, *Br.* W.

SYRUPUS ACACIÆ. *U. S. Syrup of Gum Arabic.*

"Take of Gum Arabic, in pieces, *two troyounces;* Sugar [refined], in coarse powder, *fourteen troyounces;* Water *eight fluidounces.* Dissolve in the Water, first, the Gum Arabic without heat, then the Sugar with a gentle heat, and strain." *U. S.*

The gum should be carefully selected; and, if its solution contain impurities, it should be strained before the addition of the sugar. On the whole, taking into consideration the great liability to the use of materials not quite pure, it might be advisable, in all cases, to heat momentarily to the boiling point, skim off what may rise to the surface, and then strain. This syrup is useful in the preparation of mixtures, pills, and troches, and is a good demulcent; but unfortunately the proportion of the gum to the sugar is too small to meet all the indications calling for the conjoint use of these two substances, and could not be much increased without endangering the stability of the preparation. W.

SYRUPUS ACIDI CITRICI. *U. S. Syrup of Citric Acid.*

"Take of Citric Acid, in fine powder, *one hundred and twenty grains;* Oil of Lemon *four minims;* Syrup *two pints.* Rub the Citric Acid and Oil of Lemon with a fluidounce of the Syrup; then add the mixture to the remainder of the Syrup, and dissolve with a gentle heat." *U. S.*

This is more uniform in its character, keeps better, and is more readily prepared than lemon syrup, but does not equal it in flavour, if the latter is well made. If long kept it is apt to acquire a musty taste, and to deposit grape sugar copiously, in consequence of the action of the acid on the cane sugar. It is much employed as an agreeable and refrigerant addition to drinks, especially carbonic acid water. Tartaric acid, on account of its greater cheapness, has not unfrequently been substituted for the citric; but the syrup made with it does not keep so well, and, moreover, is more apt to irritate the stomach.

Off. Prep. Liquor Magnesiæ Citratis, *U. S.* W.

SYRUPUS ALLII. *U. S. Syrup of Garlic.*

"Take of Garlic, sliced and bruised, *six troyounces;* Sugar [refined], in coarse powder, *twenty-four troyounces;* Diluted Acetic Acid *a pint.* Macerate the Garlic with ten fluidounces of the Diluted Acetic Acid, in a glass vessel, for four days, and express the liquid. Then mix the residue with the remainder of the Acid, and again express until sufficient additional liquid has been obtained to make the whole, when filtered, measure a pint. Lastly, introduce the Sugar into a two-pint bottle, pour upon it the filtered liquid, and agitate until it is dissolved." *U. S.*

This preparation is made upon correct principles; as vinegar is a better solvent of the active matter of garlic than water. The syrup is given in chronic catarrhal affections of the lungs, and is particularly beneficial in infantile cases,

by the stimulus which it affords to the nervous system. A teaspoonful may be given for a dose to a child a year old. W.

SYRUPUS AMYGDALÆ. *U.S. Syrup of Almond. Syrup of Orgeat.*

"Take of Sweet Almond *twelve troyounces;* Bitter Almond *four troyounces;* Sugar [refined], in coarse powder, *seventy-two troyounces;* Water *three pints.* Having blanched the Almonds, rub them in a mortar to a very fine paste, adding, during the trituration, three fluidounces of the Water and twelve troyounces of the Sugar. Mix the paste thoroughly with the remainder of the Water, strain with strong expression, add to the strained liquid the remainder of the Sugar, and dissolve it with the aid of a gentle heat. Lastly, strain the solution through muslin, and, having allowed it to cool, keep it in well-stopped bottles in a cool place." *U. S.*

This process corresponds closely with that of the French Codex. Orange-flower water, however, which is an ingredient of the French preparation, is wanting in ours. It may be added to the syrup, in the quantity of half a pint, immediately after the sugar is dissolved.

For a modified formula for preparing syrup of orgeat, by M. Capdeville, the reader is referred to the *American Journal of Pharmacy* (xxvii. 450), in which it is copied from the *Repert. de Pharm.* of January, 1855.

This is an elegant syrup, much employed in Europe, and occasionally in this country. It is demulcent, nutritive, and, in consequence of the hydrocyanic acid of the bitter almonds, somewhat sedative. It is said to impair greatly the odour of musk and assafetida, when mixed with them. It may be added to cough mixtures, or used for flavouring drinks in complaints of the chest. W.

SYRUPUS AURANTII CORTICIS. *U.S.* SYRUPUS AURANTII. *Br. Syrup of Orange Peel.*

"Take of Sweet Orange Peel, recently dried and in moderately fine powder, *two troyounces;* Carbonate of Magnesia *half a troyounce;* Sugar [refined], in coarse powder, *twenty-eight troyounces;* Alcohol, Water, each, *a sufficient quantity.* Moisten the Orange Peel with half a fluidounce of Alcohol, introduce it into a conical percolator, and pour Alcohol upon it until six fluidounces of tincture have passed. Evaporate this, at a temperature not exceeding 120°, to two fluidounces, add the Carbonate of Magnesia and a troyounce of the Sugar, and rub them together, gradually adding half a pint of Water during the trituration. Then filter, and, having added sufficient water to make the liquid measure a pint, dissolve in it the remainder of the Sugar with the aid of a gentle heat, and strain." *U. S.*

"Take of Tincture of Orange Peel *one fluidounce;* Syrup *seven fluidounces.* Mix." *Br.*

The present U. S. formula is a great improvement over that of 1850, in which water was used as the menstruum, and consequently but little relatively of the volatile oil of the rind was extracted. Not only is alcohol used, but afterwards, when, the greater part of the alcohol having been evaporated as no longer needed, water is added, care is taken, by rubbing this and the concentrated tincture with carbonate of magnesia, to enable the water to take up and hold in solution the oil extracted by the alcohol. The present syrup is consequently much more highly flavoured than the one which it has superseded. In the evaporation it is important that the heat should not exceed 120°, in consequence of the volatile nature of the active principle of the peel; and, to facilitate the solution of the sugar, it should be previously powdered. The British preparation, which is a mere mixture of the tincture with syrup, is in all respects inferior. The U. S. formula is that of Prof. Procter, which was published in the eleventh edition of the U. S. Dispensatory (*page* 1274). The use of carbonate of magnesia was first suggested by Mr. John D. Finley.

The syrup has an agreeable flavour, for which alone it is employed. Prepared according to the U. S. process of 1850, it was apt to ferment in warm weather; an objection to which the present syrup is not liable.

Off. Prep. Confectio Sulphuris, *Br.* W.

SYRUPUS AURANTII FLORUM. *U.S.* SYRUPUS AURANTII FLORIS. *Br.* *Syrup of Orange Flowers.*

"Take of Orange Flower Water *five fluidounces;* Sugar [refined], in coarse powder, *thirty-six troyounces;* Distilled Water *fifteen fluidounces.* Dissolve the Sugar in the Distilled Water, with the aid of a gentle heat, and raise the temperature to the boiling point. When the solution is nearly cold, mix thoroughly with it the Orange Flower Water, and strain." *U. S.*

"Take of Orange-flower Water *eight fluidounces;* Refined Sugar *three pounds* [avoirdupois]; Distilled Water *sixteen fluidounces,* or *a sufficiency.* Dissolve the Sugar in the Distilled Water, by means of heat; strain, and when nearly cold add the Orange-flower Water, with a sufficient quantity of Distilled Water, if necessary, to make the product four pounds and a half [avoird.]. The sp. gr. should be 1·330." *Br.*

This is used chiefly for flavouring mixtures. The dose is a fluidrachm. W.

SYRUPUS FERRI IODIDI. *U.S.*, *Br.* LIQUOR FERRI IODIDI. *U.S.* 1850. *Syrup of Iodide of Iron. Solution of Iodide of Iron.*

"Take of Iodine *two troyounces;* Iron, in the form of wire and cut in pieces, *three hundred grains;* Distilled Water *three fluidounces;* Syrup *a sufficient quantity.* Mix the Iodine, Iron, and Distilled Water in a flask of thin glass, shake the mixture occasionally until the reaction ceases, and the solution has acquired a green colour and lost the smell of iodine. Then, having introduced a pint of Syrup into a graduated bottle, heat it by means of a water-bath to 212°, and through a small funnel inserted in the mouth of the bottle, filter into it the solution already prepared. When this has passed, close the bottle, shake it thoroughly, and, when the liquid has cooled, add sufficient Syrup to make the whole measure twenty fluidounces. Lastly, again shake the bottle, and transfer its contents to two-ounce vials, which must be well stopped." *U.S.*

"Take of fine Iron Wire *one ounce* [avoirdupois]; Iodine *two ounces* [avoird.]; Refined Sugar *twenty-eight ounces* [avoird.]; Distilled Water *thirteen fluidounces.* Prepare a syrup by dissolving the Sugar in ten [fluid]ounces of the Water with the aid of heat. Digest the Iodine and the Iron Wire in a flask, at a gentle heat, with the remaining three [fluid]ounces of the Water, till the froth becomes white; then filter the liquid, while still hot, into the syrup, and mix. The product should weigh two pounds eleven ounces [avoird.], and should have the sp. gr. 1·385. It contains 4·3 grains of iodide of iron in a fluidrachm." *Br.*

These preparations furnish solutions of iodide of iron, rendered more permanent by sugar. The mode of making the iodide is precisely the same as that given under the head of *Ferri Iodidum.* The gentle heat employed in the British process is unnecessary. The iodine should be quite dry; as, if moist, as British iodine often is, less iodide of iron will be formed and the syrup will be proportionably weaker. In both processes a large excess of iron is taken, being greatest in the British. A moderate excess is useful in preventing the solution of iodide of iron from undergoing any change from the absorption of oxygen during filtration, before it comes in contact with the sugar. Assuming that the iodine without loss is all converted into iodide of iron, it is easy to calculate the strength of the officinal solutions. Thus, it will be found that the U. S. solution contains 7·33 grains, and that of the British Pharmacopœia about 4·30 grains of the dry iodide to the fluidrachm. In both preparations there is sufficient sugar to constitute a syrup; the present U. S. process differing in this respect from that of 1850, which was denominated a solution, because containing insufficient sugar to be entitled to the name of a syrup. Indeed, the proportion of sugar in the old formula was insufficient duly to protect the iodide, and was therefore increased. In the solution of 1850, a coil of iron wire, or a strip of bright iron, immersed in the solution, was found to assist in preserving it from change.

The plan of protecting the solution of iodide of iron from change by saccharine matter originated with M. Frederking, of Riga, who published a formula

for the purpose in *Buchner's Repertorium* in 1839. The same plan was proposed in a paper by Prof. Procter, contained in the *Amer. Journ. of Pharmacy* for April, 1840. In the *Journal de Pharmacie* for March, 1841, Dr. Dupasquier, of Lyons, claims to have made a pure iodide of iron, protected by syrup of gum, as early as 1838. In the *Pharm. Journ.* for August, 1841, the late Dr. A. T. Thomson published a paper in which he confirmed the results of Frederking and Procter, and proposed a formula for a *strong syrup*, which is the basis of that adopted by the British Pharmacopœia.

Properties. The *U. S. syrup of iodide of iron* is a transparent liquid, of a pale-green colour, and deposits no sediment on being kept; nor does it tinge a solution of starch blue, showing that it is well protected. In regard to the former U. S. preparation, Mr. E. S. Wayne observed that, when kept for some time, it occasionally deposited grape sugar, into which the cane sugar was converted, probably through the agency of hydriodic acid. According to Mr. J. M. Maisch, of this city, the solution was decomposed not only by light, but also by the action of atmospheric oxygen in bottles partly filled and frequently opened. The oxidation of the iron and the evolution of the iodine were accelerated by the action of light, when the solution was thus insecurely kept; but, when the altered solution was transferred to air-tight bottles, completely filled, and exposed to the direct light of the sun, it resumed its transparency; and its original colour was restored, or rendered much lighter. After this restoration the solution could not be the same; and Mr. Maisch thought it probable that it contained some iodate of sesquioxide of iron. (See his papers in the *Am. Journ. of Pharm.* for Sept. 1854, and May, 1855.) The removal of the apparent defects of a solution of iodide of iron by the action of sunlight is, therefore, not an admissible expedient; because it changes the nature of the solution. Mr. Maisch discovered copper in a sample of this preparation. It may be detected by putting into the solution a piece of bright iron, which, by a prolonged contact, will be covered with copper, if that metal be present. Syrup of iodide of iron is rendered brown by sulphuric acid, and emits violet vapors when heated. It should not contain any free iodine, which, if present, may be detected by the production of a blue colour with starch.

These observations of Mr. Maisch in reference to the former Liquor Ferri Iodidi, so far as concerns the influence of light, are probably true of the present syrup, though the greater proportion of sugar contained gives it, no doubt, additional protection against the oxidizing influence of the air.

Dr. Squibb states, in a communication to the *American Journal of Pharmacy* (March, 1868, p. 99), that, after considerable experience with the U. S. preparation, he has known it to become discoloured only in one instance; so that with care to avoid all injurious exposure it may be expected to keep well. But, in consequence of the facility with which it undergoes decomposition, with the liberation of iodine, it is very liable to become discoloured with the least want of care. He, therefore, proposes, as a remedy for this inconvenience, to add to the discoloured syrup a very small proportion of a solution of hyposulphite of soda, which, without injury to the preparation, removes the colour, and in a great degree restores the transparency. For this purpose fifteen or twenty grains of the crystallized hyposulphite may be dissolved in a fluidounce of water; and from fifteen to twenty minims of the solution are sufficient for a pint of syrup, if not darker than brown sherry. The solution is simply added to the syrup, and shaken up with it in the bottle. If the discolouration be deeper, more will be required; and the quantity requisite for the effect is a measure of the amount of change that may have occurred. Glycerin has been proposed as a substitute for sugar in this preparation, and it answers the same purpose, but it may be doubted whether more effectually. Such a preparation, however, would come properly under the Glycerates of the Br. Pharmacopœia.

When the syrup is concentrated it becomes brown, and, when evaporated to dryness, forms a mass which may be called *saccharine iodide of iron*, and which is not entirely soluble again, a little sesquioxide of iron being left. This saccha-

rine iodide, being protected by the sugar it contains, is not liable to the objections which apply to the pure solid salt, and may be made into pills.

Medical Properties. These have been detailed under the head of *Ferri Iodidum.* The dose of the syrup is from 20 to 40 minims, diluted with water. The dilution should be made at the moment it is taken; and, in order to guard against injury to the teeth, the mouth should be carefully washed after each dose.

Solution of iodide of iron is sometimes used as an external application; and when so employed, the necessary dilution should be made at the moment of applying it. B.

SYRUPUS FERRI PHOSPHATIS. *Br. Syrup of Phosphate of Iron.*

"Take of Granulated Sulphate of Iron *two hundred and twenty-four grains;* Phosphate of Soda *two hundred grains;* Acetate of Soda *seventy-four grains;* Diluted Phosphoric Acid *five fluidounces and a half;* Refined Sugar *eight ounces* [avoirdupois]; Distilled Water *eight fluidounces.* Dissolve the Sulphate of Iron in four [fluid]ounces of the Water, and the Phosphate and Acetate of Soda in the remainder; mix the two solutions, and, after careful stirring, transfer the precipitate to a calico filter, and wash it with Distilled Water, till the filtrate ceases to be affected by chloride of barium. Then press the precipitate strongly between folds of bibulous paper, and add to it the Diluted Phosphoric Acid. As soon as the precipitate is dissolved, filter the solution, add the Sugar, and dissolve without heat. The product should measure exactly twelve fluidounces." *Br.*

The first part of this process is almost precisely a repetition of that of the Br. Pharmacopœia for phosphate of iron. (See *Ferri Phosphas.*) But after that salt has been prepared, instead of being dried, it is first strongly pressed, and then dissolved in the dilute phosphoric acid, and made into a syrup with sugar. As the phosphate of iron is insoluble in water, it was necessary to have recourse to an acid to effect its solution, and the phosphoric acid was selected as therapeutically co-indicated. Each fluidrachm contains one grain of the phosphate of iron. (*Br.*) For its properties and uses, see *Ferri Phosphas* (page 1186). The dose is one or two fluidrachms. W.

SYRUPUS HEMIDESMI. *Br. Syrup of Hemidesmus. Syrup of Indian Sarsaparilla.*

"Take of Hemidesmus Root, bruised, *four ounces* [avoirdupois]; Refined Sugar *twenty-eight ounces* [avoird.]; Boiling Distilled Water *one pint* [Imperial measure]. Infuse the Hemidesmus in the Water, in a covered vesssel, for four hours, and strain. Set it by till the sediment subsides; then decant the clear liquor, add the Sugar, and dissolve by means of a gentle heat. The product should weigh two pounds ten ounces, and should have the specific gravity 1·335."

This is a very weak preparation. The dose is stated at one fluidrachm, but the syrup may be taken almost ad libitum. (See *Hemidesmus.*) W.

SYRUPUS IPECACUANHÆ. *U. S. Syrup of Ipecacuanha.*

"Take of Fluid Extract of Ipecacuanha *two fluidounces;* Syrup *thirty fluidounces.* Mix them." *U. S.*

By the former U. S. process of 1850, a tincture of ipecacuanha was first formed with diluted alcohol, then reduced by evaporation so as to drive off the alcohol, and afterwards diluted with water and made into a syrup with sugar. The present process simply mixes the fluid extract, which is an officinal preparation, with syrup. The French Codex dissolves the alcoholic extract of ipecacuanha in water, and then mixes it with syrup; but it is obvious that the U. S. plan is preferable, as it spares the continued heat requisite to reduce the tincture to dryness. The present U. S. syrup, which is twice as strong as that of 1850, is made in accordance with the suggestions of Mr. Laidley, of Richmond, Va., who found the syrup, as ordinarily prepared, to spoil by keeping. (*Am. Journ. of Pharm.*, xxvi. 103.)

This syrup is chiefly applicable to the cases of children. One fluidounce of it,

prepared according to the U. S. formula, should contain the virtues of thirty grains of ipecacuanha. The dose of it, as an emetic, is for an adult from four fluidrachms to a fluidounce, for a child a year or two old, from thirty minims to a fluidrachm, repeated every fifteen or twenty minutes till it acts. As an expectorant, the dose for an adult is thirty minims or a fluidrachm, for a child from two to ten minims. W.

SYRUPUS KRAMERIÆ. *U. S. Syrup of Rhatany.*

"Take of Rhatany, in moderately fine powder, *twelve troyounces;* Sugar [refined], in coarse powder, *thirty troyounces;* Water *a sufficient quantity.* Mix the Rhatany with half a pint of Water, and, having allowed the mixture to stand for two hours, introduce it into a glass percolator, and gradually pour Water upon it until four pints of filtered liquor are obtained. Evaporate this, by means of a water-bath, to seventeen fluidounces, and, having added the Sugar, dissolve it with the aid of a gentle heat, and strain the solution while hot. This Syrup may also be prepared in the following manner.

"Take of Extract of Rhatany *two troyounces;* Sugar, in coarse powder, *thirty troyounces;* Water *a pint.* Dissolve the Extract in the Water, and filter; then, having added the Sugar, dissolve it with the aid of a gentle heat, and strain the solution while hot." *U. S.*

As rhatany yields a variable proportion of extract, it follows that the syrup resulting from these two modes of preparation must differ. To obviate this evil as far as possible, care should be taken, in following the first process, to select the best rhatany, and preferably the small roots, as it is these only which will yield two ounces of good extract to the pound.

In the second process, extract of rhatany as free as possible from insoluble matter should be chosen; and that prepared according to the U. S. directions will be found the best. (See *Extractum Krameriæ.*) This preparation affords a convenient mode of exhibiting rhatany to infants. The dose for an adult is half a fluidounce, for a child a year or two old, twenty or thirty minims. W.

SYRUPUS LACTUCARII. *U. S. Syrup of Lactucarium.*

"Take of Lactucarium *a troyounce;* Syrup *fourteen fluidounces;* Diluted Alcohol *a sufficient quantity.* Rub the Lactucarium with sufficient Diluted Alcohol, gradually added, to bring it to a syrupy consistence. Then introduce it into a conical percolator, and, having carefully covered the surface with a piece of muslin, gradually pour Diluted Alcohol upon it until half a pint of tincture has passed. Evaporate this, by means of a water-bath, at a temperature not exceeding 160°, to two fluidounces, mix it with the Syrup, previously heated, and strain while hot." *U. S.*

This syrup has the virtues of lactucarium, free from its inert albuminous matter. It is, however, objectionable on account of its want of transparency, and in some measure also from its disagreeable taste. The former of these objections it has been proposed to obviate by the use of carbonate of magnesia as in the U. S. formula for Syrup of Tolu; the latter by the addition of one of the aromatic Waters. When the tincture obtained by percolation in the above process is reduced to two fluidounces, a deposition takes place of active matter, which is afterwards in part lost, in the straining, and in part, so far as redissolved by means of the heat, is subsequently deposited or held suspended in the syrup. Mr. P. M. Bedford proposes to rub the tincture before evaporation, and four fluidounces of water, in a mortar, with a drachm of carbonate of magnesia and a troyounce of sugar, then to filter, evaporate at 160° to six fluidounces, add thirteen ounces of sugar to form a syrup, and when this is nearly cool, to pour it into a bottle containing two fluidounces of Orange-flower Water. If necessary, water is to be added to make the measure of a pint. The rubbing with carbonate of magnesia enables the menstruum to take up, as far as it is capable of doing, the matter that would otherwise be deposited. The proportions of the ingredients are essentially those of the U.S. process. (*Am. Journ. of Pharm.*, Jan. 1869, p. 48.) A proceeding somewhat similar to Mr. Bed-

ford's, but using powdered pumice-stone instead of carbonate of magnesia, and rubbing this and a little sugar with the tincture after evaporation instead of previously, has been recommended by Mr. James Kenworthy, who assures us that the result is a beautifully clear syrup, with the flavour and appearance of Aubergier's, and the virtues of that of the U. S. Pharmacopœia. (*Ibid.*, March, 1868, p. 113.)* The dose is two or three fluidrachms. W.

SYRUPUS LIMONIS. *U. S.*, *Br.* *Syrup of Lemon.*

"Take of Lemon Juice, recently expressed and strained, *a pint;* Sugar [refined], in coarse powder, *forty-eight troyounces;* Water *a pint.* Mix the Lemon Juice and Water, and, having added the Sugar to the mixture, dissolve it with the aid of a gentle heat, and strain the solution while hot." *U. S.*

"Take of Fresh Lemon Peel *two ounces* [avoirdupois]; Lemon Juice, strained, *one pint* [Imperial measure]; Refined Sugar *two pounds and a quarter* [avoird.]. Heat the Lemon Juice to the boiling point, and, having put it into a covered vessel with the Lemon Peel, let them stand until they are cold, then filter, and dissolve the Sugar in the filtered liquid with a gentle heat. The product should weigh three pounds and a half [avoird.], and should have the sp. gr. 1·34." *Br.*

The British preparation has an advantage over that of the U. S. Pharmacopœia in possessing more of the aromatic flavour of the rind; and it would be an improvement to our formula to add a little grated fresh lemon-peel to the other ingredients. In the present U. S. syrup, the juice, instead of being used undiluted, as in the process of 1850, is mixed with an equal measure of water, which is an improvement.

This syrup forms a cooling and grateful addition to beverages in febrile complaints, and serves to conceal the taste of saline purgatives in solution. W.

SYRUPUS MORI. *Br.* *Syrup of Mulberries.*

"Take of Mulberry Juice *one pint* [Imperial measure]; Refined Sugar *two pounds* [avoirdupois]; Rectified Spirit *two fluidounces and a half.* Heat the

* *Aubergier's Syrup of Lactucarium.* Though probably inferior in efficacy to the U. S. syrup, that of Aubergier has a great reputation on the continent of Europe, and is occasionally prescribed here instead of the officinal. It differs so much from ours, that, when it is prescribed, the apothecary who may not have it on hand should not substitute the officinal for it, unless with the full knowledge of the prescriber. In order to obviate this inconvenience, it is advisable that there should be a formula, readily accessible, by which a syrup may be prepared, sufficiently representing Aubergier's for all practical purposes. Prof. Procter, therefore, has done the profession good service by preparing and publishing such a process, which we copy here. "Take of Lactucarium (German) *half an ounce;* Granulated Sugar *an ounce;* Simple Syrup *four and a half pints;* Citric Acid, in powder, *sixty grains;* Orange-flower Water *four fluidounces;* Diluted Alcohol, Water, each, *a sufficient quantity.* Triturate the Lactucarium with the Sugar until reduced to powder, put it into a funnel-shaped percolator, pour on Diluted Alcohol until the Lactucarium is nearly exhausted, or until ten fluidounces have passed, evaporate to two fluidounces, and add it to the Syrup, previously heated by boiling, and mix. Continue the ebullition slowly until the whole measures four pints and six fluidounces. Then add the Citric Acid and strain, and, lastly, when nearly cool, the Orange-flower Water, and mix them. Each fluidounce contains the strength of three and one-third grains of lactucarium. The syrup is light-brown and transparent." (*Am. Journ. of Pharm.*, July, 1866, p. 290.)

The French Codex has a syrup, called *Opiated Syrup of Lactucarium* (*Sirop de Lactucarium Opiacé*), in which an alcoholic extract is used in double the quantity of extract of opium. One would suppose that, in such a proportion, the action of the opium would entirely overwhelm that of the lactucarium; but we are assured by M. Deschamps, as the well-ascertained result of experiments of his own and the late M. Debout, that lactucarium given with opium very decidedly opposes, even in small proportion, the unpleasant effects caused by opium, such as nausea, stomachic spasms, headache, &c. (*Ann. de Thérap.*, 1868, p. 17); and hence the advantage of a preparation in which the two narcotics are combined. But to gain all the good results of this experience, it is unnecessary to add a new syrup to the officinal list; all that is requisite being the addition of a little of the simple syrup of lactucarium to any preparation of opium, the anticipated unpleasant effects of which it is desirable to prevent. (*Note to the thirteenth edition.*)

Mulberry Juice to the boiling point, and when it has cooled filter it. Dissolve the Sugar in the filtered liquid with a gentle heat, and add the Spirit. The product should weigh three pounds six ounces [avoird.], and should have the sp. gr. 1·33." *Br.*

This may be used for the same purposes with lemon syrup. In like manner syrups may be prepared from various succulent fruits, such as *strawberries, raspberries, blackberries, currants, pineappies,* &c. When the juice is thick, it may be diluted with from one-third of its bulk to an equal bulk of water previously to the addition of the sugar. In the preparation of *raspberry syrup,* which, as ordinarily made, is apt to gelatinize, M. Blondeau recommends that the strained juice be allowed to stand from eight to fifteen hours, according to the temperature, in order to ferment. The juice separates into two portions, the upper thick, the lower clear. The latter is to be separated by straining, and made into a syrup with the usual proportion of sugar. The process of the London College for Syrupus Mori, retained in the first British Pharmacopœia, is in accordance with this recommendation. These syrups are employed to flavour drinks, and are much used as grateful additions to carbonic acid water.* W.

SYRUPUS PAPAVERIS. *Br. Syrup of Poppies.*

"Take of Poppy Capsules, dried, freed from the seeds, and coarsely powdered, *thirty-six ounces* [avoirdupois]; Rectified Spirit *sixteen fluidounces;* Refined Sugar *four pounds* [avoird.]; Boiling Distilled Water *a sufficiency.* Mix the Poppy Capsules with four pints [Imperial measure] of the Water, and infuse for twenty-four hours, stirring them frequently; then pack them in a percolator, and adding more of the Water, allow the liquor slowly to pass until about two gallons [Imp. meas.] have been collected, or the poppies are exhausted. Evaporate the liquor by a water-bath until it is reduced to three pints [Imp. meas.]. When quite cold, add the Spirit, let the mixture stand for twelve hours, and filter. Distil off the spirit, evaporate the remaining liquor to two pints [Imp. meas.], and then add

* Some practical remarks in relation to these syrups, so much used with artificial mineral water, may prove useful to the inexperienced pharmaceutist. Care should be taken that the fruit employed should be fully ripe, and freed from all its natural attachments, as calyx, stem, &c., and from all other impurities. Without being previously crushed, it should be put into canvass or woollen bags, which should be about two-thirds full when placed under the press. The expressing force should be gradually increased, so as effectually to remove the juice with as little of the tissue of the fruit as possible. It is customary to make a pint of syrup from a pint measure of fruit, and, if the expressed juice is insufficient for the purpose, to dilute it with water; but this is obviously an arbitrary rule, which cannot be universally applied without injuriously affecting the character of the product. The rule in the text is better; viz., to dilute the juice when too thick. In dissolving the sugar, as short an exposure to heat as possible is desirable. Some dissolve the sugar in a portion of the juice with heat, and add the remainder a few minutes before removal from the fire. Some fruits contain so much pectin that their syrups are apt to gelatinize. This is particularly the case with currants and raspberries. A mode of preventing this result has been mentioned in the text. Another method is to add to the juice, after expression, one-tenth of its bulk of the juice of sour cherries, allow the mixture to stand for fifteen hours, and then separate the coagulated pectin by very gentle pressure in a cloth. *Pineapple* syrup may be made either in the ordinary mode, or by slicing the fruit, alternating the slices with layers of powdered sugar, permitting them to stand twenty-four hours, and then expressing the syrup formed. Each pound of the pared fruit, with thirty ounces of sugar, should yield with the requisite quantity of water two pints of syrup. For some further practical remarks on the preparation of particular syrups, the reader is referred to a paper by Mr. Ambrose Smith, in the *American Journal of Pharmacy* (xxii. 212).

Cream Syrups. Under this name, there has come into use, in Philadelphia, a variety of syrups, given with carbonic acid water, to which they impart an agreeable richness of flavour. To prepare them, a gallon of fresh sweet cream is made to dissolve, without heat, 14 pounds (avoird.) of powdered sugar; and the solution, having been immediately bottled, is placed on ice, in a cold cellar. It will keep from three to eight days, according to circumstances. It is added to other syrups, given with carbonic acid water, equal measures being employed. The use of cream syrups is said to have originated with Mr. C. A. Smith, of Cincinnati. Mr. A. B. Taylor, of Philadelphia, prepares *cream vanilla syrup* by mixing together three fluidrachms of strong fluid extract of vanilla, a pint of simple syrup, and a pint of cream syrup. (*Am. Journ. of Pharm.*, xxvii. 407.)—*Notes to the ninth and eleventh editions.*

the Sugar. The product should weigh six pounds and a half [avoird.], and should have the sp. gr. 1·320." *Br.*

As the capsules contain variable proportions of the narcotic principle, the syrup prepared from them is necessarily of variable strength. It was, moreover, as formerly prepared, very apt to spoil. It is, we presume, to correct this tendency, that the direction is given in the Pharmacopœia to add alcohol to the infusion, by which coagulable matter may be separated; the alcohol itself being subsequently removed by distillation. The place, however, of this syrup, might, with great propriety, be supplied by a syrup prepared from one of the salts of morphia, which would keep well, and have the advantage of uniform strength. Four grains of the sulphate of morphia dissolved in a pint of syrup, would afford a preparation at least equal to the average strength of the syrup of poppies, and much more certain in its operation. Mr. Southall recommends that the syrup of poppies should be prepared with a cold infusion made by percolation; the same proportions being employed as directed by the late London Pharmacopœia. The virtues of the capsules are thus extracted without those principles which cause the syrup to ferment speedily. (See *Am. Journ. of Pharm.*, xv. 140.) Mr. Southall, after preparing the infusion, evaporates it to the proper measure before adding the sugar. Mr. Stockton prefers adding the sugar before the concentration is completed, and afterwards evaporating to 32° of the saccharometer. (*Pharm. Journ.*, xi. 299.) It is probable that a syrup, prepared with diluted alcohol as the menstruum, would keep better than that made on either of the above plans.*

The syrup of poppies is employed, chiefly in infantile cases, to allay cough, quiet restlessness, relieve pain, and promote sleep. The dose is from half a fluidrachm to a fluidrachm for an infant, from half a fluidounce to a fluidounce for an adult. W.

SYRUPUS PRUNI VIRGINIANÆ. *U. S.* *Syrup of Wild-cherry Bark.*

"Take of Wild-cherry Bark, in coarse powder, *five troyounces;* Sugar [refined], in coarse powder, *twenty-eight troyounces;* Water *a sufficient quantity.* Moisten the Bark thoroughly with Water, and allow it to stand for twenty-four hours in a close vessel; then pack it firmly in a glass percolator, and gradually pour Water upon it until a pint of filtered liquor is obtained. To this, transferred to a bottle, add the Sugar, and agitate occasionally until it is dissolved." *U. S.*

This process affords a handsome syrup, with the virtues of the bark unimpaired by the injurious effects of heat. It is based upon a formula proposed by Messrs. Procter and Turnpenny in the *American Journal of Pharmacy* (xiv. 27). It probably more precisely represents the bark than is done by the fluid extract, which contains a smaller proportion of the tannic acid than the bark, in consequence of the removal of a part of that principle by combination with the albumen of the almonds used in the process. In some cases, this want of tannic acid may specially recommend the fluid extract; while in others, as in the diarrhœa of phthisis, for example, the syrup or infusion might be preferable from retaining it. The dose is half a fluidounce. W.

SYRUPUS RHAMNI. *Br.* *Syrup of Buckthorn.*

"Take of Buckthorn Juice *four pints* [Imperial measure]; Ginger sliced, Pimento, bruised, of each *three-quarters of an ounce* [avoirdupois]; Refined Sugar *five pounds* [avoird.], or *a sufficiency;* Rectified Spirit *six fluidounces*

* Prof. Procter has furnished us with the following formula, which he has used for many years, and found to yield a good syrup, that will keep well. "Take of Poppy Capsules, deprived of their seeds, and ground into coarse powder, *eight troyounces;* Sugar *fifteen troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with four fluidounces of the Diluted Alcohol, pack it firmly in a percolator, and pour Diluted Alcohol upon it until three pints have slowly passed. Distil off the alcohol until the residual liquid is reduced to half a pint, and filter. Allow sufficient Distilled Water to pass through the filter to make the filtrate measure half a pint; then add the Sugar, dissolve with heat, and strain." (*Note to the twelfth edition.*)

[Imp. meas.]. Evaporate the Juice to two pints and a half [Imp. meas.], add the Ginger and Pimento, digest at a gentle heat for four hours, and strain. When cold add the Spirit, let the mixture stand for two days, then decant off the clear liquor, and in this dissolve the Sugar with a gentle heat, so as to make the specific gravity 1·32." *Br.*

This syrup was officinal with the Lond. and Ed. Colleges, and, though dropped at the formation of the original British Pharmacopœia, seems to have so strong a hold on practitioners that it was deemed expedient to resume it in the present code. Though an efficient cathartic, it seems never to have been much used in this country, probably because, the plant not being indigenous or cultivated here, the fresh juice could not be readily obtained. The dose is a fluidrachm. W.

SYRUPUS RHEI. *U. S., Br. Syrup of Rhubarb.*

"Take of Fluid Extract of Rhubarb *three fluidounces;* Syrup *twenty-nine fluidounces.* Mix them thoroughly." *U. S.*

"Take of Rhubarb Root, in coarse powder, Coriander Fruit, in coarse powder, of each *two ounces* [avoirdupois]; Refined Sugar *twenty-four ounces* [avoird.]; Rectified Spirit *eight fluidounces* [Imperial measure]; Distilled Water *twenty-four fluidounces* [Imp. meas.]. Mix the Rhubarb and Coriander; pack them in a percolator; pass the Spirit and Water, previously mixed, slowly through them; evaporate the liquid that has thus passed until it is reduced to thirteen fluidounces [Imp. meas.], and in this, after it has been filtered, dissolve the Sugar with a gentle heat." *Br.*

This is a new officinal of the Br. Pharmacopœia, and corresponds nearly with the U. S. syrup, except in the presence of coriander, which is perhaps better omitted, as allowing the practitioner to accommodate the aromatic addition to the taste of his patient. The U. S. formula is an improvement on that of 1850, as being more precise. The syrup is a mild cathartic, adapted to the cases of infants, to whom it may be given in the dose of a fluidrachm. W.

SYRUPUS RHEI AROMATICUS. *U. S. Aromatic Syrup of Rhubarb.*

"Take of Rhubarb, in moderately fine powder, *two troyounces and a half;* Cloves, in moderately fine powder, Cinnamon, in fine powder, each, *half a troyounce;* Nutmeg, in moderately fine powder, *one hundred and twenty grains;* Syrup *six pints;* Diluted Alcohol *a sufficient quantity.* Mix the powders, and, having moistened the mixture with two fluidounces of Diluted Alcohol, introduce it into a conical percolator, and pour Diluted Alcohol upon it until a pint of tincture has passed. Add this to the syrup, previously heated, and mix them thoroughly." *U. S.**

The aromatic syrup of rhubarb is a warm stomachic laxative, too feeble for adult cases, but well calculated for the bowel-complaints of infants which are so frequent in our cities during the summer season, and as a remedy for which this preparation, or one analogous to it, has been long in use under the name of *spiced syrup of rhubarb.* The dose for an infant with diarrhœa is a fluidrachm, repeated every two hours till the passages indicate by their colour that the medicine has operated. It should be borne in mind that the syrup, as prepared by the present formula, contains one-seventh of diluted alcohol, which, though not injurious in most of the cases in which this syrup is used, might render it too stimulant in some instances of diarrhœa in the very young infant. W

SYRUPUS RHŒADOS. *Br. Syrup of Red Poppy.*

"Take of Fresh Red Poppy Petals *thirteen ounces* [avoirdupois]; Refined

* The following is the preferred formula of the Pharmacopœia of 1850, omitted in the present edition, in which the syrup is prepared by maceration. "Take of Rhubarb, bruised, *two ounces and a half;* Cloves, bruised, Cinnamon, bruised, each, *half an ounce;* Nutmeg, bruised, *two drachms;* Diluted Alcohol *two pints;* Syrup *six pints.* Macerate the Rhubarb and Aromatics in the Diluted Alcohol for fourteen days, and strain; then, by means of a water-bath, evaporate the liquor to a pint, and, while it is still hot, mix it with the Syrup previously heated." Care should be taken, in evaporating the tincture, not to let the heat exceed that of a water-bath, lest the aromatic oils should be driven off.

Sugar *two pounds and a quarter* [avoird.]; Distilled Water *one pint* [Imperial measure], or *a sufficiency;* Rectified Spirit *two fluidounces and a half.* Add the Petals gradually to the Water heated in a water-bath, frequently stirring, and afterwards, the vessel being removed, infuse for twelve hours. Then press out the liquor, strain, add the Sugar, and dissolve by means of heat. When nearly cold, add the Spirit, and as much Distilled Water as may be necessary to make up for loss in the process, so that the product shall weigh three pounds ten ounces. It should have the sp. gr. 1·330." *Br.*

The object of introducing the petals into water heated by a water-bath is that they may shrink by being scalded; as otherwise they could not be completely immersed in the quantity of water directed. After this has been accomplished, they should be immediately removed from the fire, lest the liquor become too thick and ropy. The fine red colour of this syrup is its only recommendation. It is very liable to ferment. The dose is stated in the Br. Pharmacopœia at a fluidrachm. W.

SYRUPUS ROSÆ GALLICÆ. *U. S., Br. Syrup of Red Rose.*

"Take of Red Rose, in moderately fine powder, *two troyounces;* Sugar [refined], in coarse powder, *eighteen troyounces;* Diluted Alcohol, Water, each, *a sufficient quantity.* Moisten the Rose with Diluted Alcohol, pack it firmly in a conical glass percolator, and gradually pour Diluted Alcohol upon it until a fluidounce of tincture has passed. Set this aside, and continue the percolation until five fluidounces more of tincture are obtained. Evaporate this with a gentle heat to a fluidounce and a half, and mix it with seven fluidounces of Water. Then, having added the Sugar, dissolve it with the aid of a gentle heat, and strain the solution while hot. Lastly, when the solution is cold, add the fluidounce of reserved tincture, and mix them thoroughly." *U. S.*

"Take of dried Red Rose Petals *two ounces* [avoirdupois]; Refined Sugar *thirty ounces* [avoird.]; Boiling Distilled Water *one pint* [Imperial measure]. Infuse the Petals in the Water for two hours, squeeze through calico, heat the liquor to the boiling point, and filter. Dissolve the Sugar in the liquor by means of heat. The product should weigh two pounds fourteen ounces [avoird.], and should have the sp. gr. 1·335." *Br.*

The syrup of red roses is mildly astringent; but is valued more for its fine red colour, on account of which it is occasionally added to mixtures. The dose is a fluidrachm. W.

SYRUPUS RUBI. *U. S. Syrup of Blackberry Root.*

"Take of Blackberry Root, in moderately fine powder, *eight troyounces;* Syrup *a pint and a half;* Diluted Alcohol *a sufficient quantity.* Introduce the powder, previously moistened with *four fluidounces* of Diluted Alcohol, into a glass percolator, and pour Diluted Alcohol upon it until a pint and a half of tincture have passed. Evaporate this, by means of a water-bath, at a temperature not exceeding 160°, to half a pint; then mix it while hot with the Syrup previously heated, and strain." *U. S.*

This process might perhaps be improved by filtering the concentrated tincture before the addition of the sugar. The Syrup is a new officinal of the U. S. Pharmacopœia, called for by the popularity of similar preparations. It is very useful in diarrhœa of relaxation, and in the chronic forms of that complaint. The dose is one or two fluidrachms. W.

SYRUPUS SARSAPARILLÆ COMPOSITUS. *U. S. Compound Syrup of Sarsaparilla.*

"Take of Sarsaparilla, in moderately coarse powder, *twenty-four troyounces;* Guaiacum Wood, in moderately coarse powder, *three troyounces;* Pale Rose, in moderately coarse powder, Senna, in moderately coarse powder, Liquorice Root, in moderately coarse powder, each, *two troyounces;* Oil of Sassafras, Oil of Anise, each, *five minims;* Oil of Gaultheria *three minims;* Sugar, in coarse powder, *ninety-six troyounces;* Diluted Alcohol *a sufficient quantity.* Mix the solid ingredients, except the Sugar, with three pints of Diluted Alco-

hol, and allow the mixture to stand for twenty-four hours; then transfer it to a cylindrical percolator, and gradually pour Diluted Alcohol upon it until ten pints of tincture have passed. Evaporate this, by means of a water-bath, to four pints, filter, and, having added the Sugar, dissolve it with the aid of heat, and strain the solution while hot. Lastly, rub the Oils with a small portion of the solution, and mix them thoroughly with the remainder." *U. S.*

In the original edition of the U. S. Pharmacopœia published in 1820, a process for a syrup of sarsaparilla was adopted, intended to represent the famous French *sirop de Cuisinier*. This was very much improved in the revised edition published in 1830; and the amended process has been retained with little alteration in the subsequent editions; the process of percolation having been substituted in the present Pharmacopœia for simple maceration directed in the first of the two formulas of 1850. In the original process, the sarsaparilla was subjected to long decoction with water. Now it has been proved that diluted alcohol more thoroughly extracts the acrid principle of the root, upon which its activity probably depends, than water, and that this principle is either dissipated or destroyed by the long-continued application of a boiling heat.* In the present formula, therefore, which employs diluted alcohol as the menstruum, the root is more completely exhausted of its active matter; while the heat applied to the concentration, being no higher than is requisite for the evaporation of the alcohol, is insufficient to injure the preparation. The spirituous menstruum has, moreover, the advantage of not dissolving the inert fecula, which encumbers the syrup prepared by decoction, and renders it liable to spoil. In the Pharmacopœia of 1840, the pale or hundred-leaved roses were very properly substituted for the red; as their slightly laxative property accords better with the character of the preparation. The operator should be careful to comply exactly with the directions of the Pharmacopœia, not only those of the present formula, including the use of the water-bath, but also the general rules given for the management of the process of percolation. The essential oils, being intended solely to communicate an agreeable flavour, are used in very small proportion. The only objection to this process is that a portion of the resin, extracted by the alcohol from the guaiacum wood, is deposited during the evaporation of the tincture; but this is separated by the filtration directed, and is therefore of no disadvantage to the preparation. But the practitioner should be aware that much of the sarsaparilla, as it exists in the market, is nearly or quite inert, and should be prepared to meet with disappointment in the use of this or any other preparation, unless satisfied of the good quality of the drug from which it is made.

Corrosive sublimate, which is often given in connection with this syrup, is said to be completely decomposed by it, being converted into calomel. M. Lepage, of Gisors, proposes as a substitute the iodohydrargyrate of potassium (see *Part* III.), which he has found not to undergo decomposition. (*Journ. de Pharm.*, 3e sér., viii. 63.)

The dose of the syrup is half a fluidounce, equivalent to somewhat less than a drachm of the root, to be taken three or four times a day. W.

SYRUPUS SCILLÆ. *U. S.*, *Br.* *Syrup of Squill.*

"Take of Vinegar of Squill *a pint;* Sugar [refined], in coarse powder, *twenty-four troyounces.* Dissolve the Sugar in the Vinegar of Squill, with the aid of a gentle heat, and strain the solution while hot." *U. S.*

"Take of Vinegar of Squill *one pint* [Imperial measure]; Refined Sugar *two pounds and a half* [avoirdupois]. Dissolve with the aid of heat." *Br.*

The present British formula is almost identical with the American, and differs from that of 1864 in taking the vinegar already formed, instead of preparing it as the first step of the process.

* See a paper by J. Hancock, M.D., republished in the *Journal of the Philadelphia College of Pharmacy* (i. 295); a communication by M. Béral to the *Journal de Pharmacie* (xv. 657); another by M. Soubeiran in the same journal (xvi. 38); and a paper by T. J. Husband in the *American Journal of Pharmacy* (xv. 6).

This syrup is much employed as an expectorant, especially in combination with a solution of tartarized antimony. The dose is about a fluidrachm. In infantile cases of catarrh and other pectoral complaints, it is sometimes given, in the same dose, as an emetic. W.

SYRUPUS SCILLÆ COMPOSITUS. *U.S.* *Compound Syrup of Squill. Hive Syrup.*

"Take of Squill, in moderately coarse powder, Seneka, in moderately fine powder, each, *four troyounces;* Tartrate of Antimony and Potassa *forty-eight grains;* Sugar [refined], in coarse powder, *forty-two troyounces;* Diluted Alcohol, Water, each, *a sufficient quantity.* Mix the Squill and Seneka, and, having moistened the mixture with half a pint of Diluted Alcohol, allow it to stand for an hour. Then transfer it to a conical percolator, and pour Diluted Alcohol upon it until three pints of tincture have passed. Boil this for a few minutes, evaporate it by means of a water-bath to a pint, add six fluidounces of boiling Water, and filter. Dissolve the Sugar in the filtered liquid, and, having heated the solution to the boiling point, strain it while hot. Then dissolve the Tartrate of Antimony and Potassa in the solution while still hot, and add sufficient boiling Water, through the strainer, to make it measure three pints. Lastly, mix the whole thoroughly together." *U. S.*

This is intended as a substitute for the popular preparation called *Coxe's hive-syrup*, from which it differs chiefly in containing sugar instead of honey. Prepared as originally directed in the Pharmacopœia, it invariably fermented from the want of sufficient concentration. This defect was corrected at the revision of 1840, when also sugar was substituted for honey, in consequence of the uncertain consistence and constitution of the latter. In the Pharmacopœia of 1850 two formulas were given for this syrup; in the first of which the virtues of the squill and seneka were extracted by long boiling with water, in the second, by percolation with water to which a small portion of alcohol was added. The latter was preferable when skilfully performed; as it avoided in great measure the injurious influence of boiling upon the seneka, exhausted both this and the squill more readily in consequence of the addition of alcohol to the menstruum, and afforded a solution of their active principles, less embarrassed with inert matters calculated to favour fermentation. In this process, the filtered liquor was raised to the boiling point in order to coagulate the albumen, after which the evaporation was conducted at a lower temperature. The present formula is a decided improvement upon the one just described; as, diluted alcohol being employed as the menstruum, less of the albuminous and mucilaginous matter is extracted; while any disadvantage from the spirituous addition is obviated by the subsequent evaporation of the alcohol and the addition of water; the provision being retained to boil the tincture for a short time to get rid of any albumen that may have been taken up.*

The compound syrup of squill combines the virtues of seneka, squill, and tartar emetic, of the last of which it contains one grain in every fluidounce. It is emetic, diaphoretic, expectorant, and frequently cathartic, and may be given

* Great difficulty has been experienced in making this preparation so as to keep well. Various improvements upon the former officinal formula have been suggested. Dr. Cummings, of Portland, Maine, proposed to use diluted acetic acid as the menstruum for squill, and diluted alcohol for seneka; and thought that a syrup might thus be made which would not ferment. (*Am. Journ. of Pharm.*, xxviii. 397.) Mr. A. P. Sharp, of Baltimore, has found great satisfaction from the following method of proceeding. As soon as one portion of the syrup has been made for use, he begins to prepare another in the following manner. Coarsely powdered seneka and squill, of each ℥viij, are macerated with a gallon of a mixture of one part of alcohol and two of water, and allowed to stand till the first portion is nearly consumed, sometimes for two or three months, when the mixture is expressed or submitted to percolation. The tincture is then evaporated, till the alcohol has been driven off, the residue is filtered cold, lbvij of sugar are added, the liquid is evaporated without boiling to Ovj, is strained if necessary, and a grain of tartar emetic added for each f℥j. (*Ibid.*, xxvii. 220.) But the improvement in the officinal formula, it is hoped, will obviate all necessity for substituted formulas in future. (*Note to the eleventh and twelfth editions.*)

with advantage in mild cases of croup, in the latter stages of severe cases when the object is to promote expectoration, and in other pectoral affections in which the same indication is presented. As an emetic, however, in croup, we prefer a simple solution of tartar emetic in water. The dose of this syrup is, for children, from ten drops to a fluidrachm, according to the age, and should be repeated in cases of croup every fifteen or twenty minutes till it vomits. As an expectorant for adults the dose is twenty or thirty drops. W.

SYRUPUS SENEGÆ. *U.S. Syrup of Seneka.*

"Take of Seneka, in moderately fine powder, *four troyounces;* Sugar [refined], in coarse powder, *fifteen troyounces;* Diluted Alcohol *two pints.* Moisten the Seneka with two fluidounces of the Diluted Alcohol; then transfer it to a conical percolator, and gradually pour upon it the remainder of the Diluted Alcohol. When the tincture has ceased to pass, evaporate it, by means of a water-bath, at a temperature not exceeding 160°, to half a pint; then filter, and, having added the Sugar, dissolve it with the aid of a gentle heat, and strain the solution while hot." *U. S.*

This is essentially the second of the two formulas given in the Pharmacopœia of 1850; the first having been omitted in the present edition, as quite superannuated. There is no doubt that, if the existing formula be carried duly into execution, it will yield an excellent preparation. But, in consequence of the abundance of a pectin-like matter in seneka, it is difficult to get the syrup quite clear without clarification with albumen. The syrup affords a very convenient mode of exhibiting seneka in pectoral complaints. It may be given as a stimulant expectorant in the dose of one or two fluidrachms. W.

SYRUPUS SENNÆ. *Br. Syrup of Senna.*

"Take of Senna, broken small, *sixteen ounces* [avoirdupois]; Oil of Coriander *three minims;* Refined Sugar *twenty-four ounces* [avoird.]; Distilled Water *five pints* [Imperial measure], or *a sufficiency;* Rectified Spirit *two fluidounces.* Digest the Senna in seventy [fluid]ounces of the Water for twenty-four hours at a temperature of 120°; press out the liquor and strain it. Digest the marc in thirty [fluid]ounces of the Water for six hours at the same temperature; again press out the liquor and strain it. Evaporate the mixed liquors in a water-bath to ten fluidounces, and, when cold, add the Rectified Spirit, previously mixed with the Oil of Coriander. Clarify by filtration, and wash what remains on the filter with Distilled Water, until the washings make up the filtrate to sixteen fluidounces. Then add the Sugar, and dissolve by means of a gentle heat. The product should weigh two pounds ten ounces [avoird.], and should have the sp. gr. 1·310." *Br.*

The present British syrup, which has superseded the former syrups of the London and Edinburgh Colleges, differs from them, as well as from that of the U. S. Pharmacopœia of 1850, very greatly in strength; so that, in prescribing it, physicians accustomed to the doses of the former syrups must be on their guard not very seriously to overdose their patients. The syrup, as made by the above formula, contains the strength of about thirty grains of senna in each fluidrachm, and should rank with the Fluid Extracts rather than the Syrups The dose for an adult would be from one to four fluidrachms; but for children, for whom it was originally intended, not more than from one-eighth to one-quarter of that quantity, according to the age It has been omitted in the present edition of the U. S. Pharmacopœia, under the impression, we presume, that its place might be supplied by the fluid extract. W.

SYRUPUS TOLUTANUS. *U. S., Br. Syrup of Tolu.*

"Take of Tincture of Tolu *two fluidounces;* Carbonate of Magnesia *one hundred and twenty grains;* Sugar [refined], in coarse powder, *twenty-six troyounces;* Water *a pint.* Rub the Tincture of Tolu first with the Carbonate of Magnesia and two troyounces of the Sugar, then with the Water gradually added, and filter. To the filtered liquid add the remainder of the Sugar, and,

having dissolved it with the aid of a gentle heat, strain the solution while hot." *U. S.*

"Take of Balsam of Tolu *one ounce and a quarter* [avoirdupois]; Refined Sugar *two pounds* [avoird.]; Distilled Water *one pint* [Imperial measure], or *a sufficiency*. Boil the Balsam in the Water for half an hour in a lightly covered vessel, stirring occasionally. Then remove from the fire, and add Distilled Water, if necessary, so that the liquid shall measure sixteen [fluid]ounces. Filter the solution when cold, add the Sugar, and dissolve with the aid of a steam or water-bath. The product should weigh *three pounds* [avoird.], and should have the sp. gr. 1·330." *Br.*

In the U. S. process, the tincture of tolu is rubbed with the carbonate of magnesia and a little sugar, and afterwards with the water, in order to enable this fluid to take from the tincture all that it is capable of dissolving; the carbonate of magnesia and the precipitated resin of the tincture being separated by filtration. The process is then completed by forming a syrup with the filtered liquid. It is in accordance with a formula proposed by Mr. J. D. Finley, and published in a note in the eleventh edition of the U. S. Dispensatory. The resulting syrup is beautifully and permanently clear, and has very decidedly the flavour of the balsam. In the British process the soluble principles of the balsam are extracted by boiling it with water, but with great waste of the material, as the water dissolves but a small portion of the active matter. To obviate this waste, the same portion of balsam is, according to Mr. Brande, usually employed in successive operations; and it long continues to impart odour and taste to boiling water. The British syrup may have an equal and possibly a finer flavour, but is less efficient medicinally than that of the U. S. Pharmacopœia. At best, however, the syrup of tolu is a feeble preparation, and is used chiefly to impart its agreeable flavour to mixtures.

Off. Prep. Trochisci Cubebæ, *U. S.* W.

SYRUPUS ZINGIBERIS. *U. S., Br. Syrup of Ginger.*

"Take of Tincture of Ginger *six fluidounces;* Carbonate of Magnesia *half a troyounce;* Sugar [refined], in coarse powder, *one hundred and eight troyounces;* Water *four pints.* Evaporate the Tincture to three fluidounces with a gentle heat; then rub it first with the Carbonate of Magnesia and two troyounces of the Sugar, and afterwards with the Water gradually added, and filter. To the filtered liquor add the remainder of the Sugar, and, having dissolved it with the aid of a gentle heat, strain the solution while hot." *U. S.*

"Take of Strong Tincture of Ginger *six fluidrachms;* Syrup *nineteen fluidounces.* Mix with agitation." *Br.*

The U. S. process for Syrup of Ginger is upon the same amended plan as that adopted for Syrup of Tolu, and yields a fine preparation entirely free from turbidness. As the active principles of ginger are soluble in water, nothing is lost by the precipitation of the concentrated tincture by means of water, and the separation of the resinous matter by filtration. The British syrup, being made by the simple incorporation of the tincture with syrup, has of course all the strength of the ginger, but is inferior to the U. S. preparation in appearance and flavour. The old plan of using water as the menstruum has been entirely abandoned, as the syrup thus made is encumbered with mucilage and starch, and consequently rendered more liable to decomposition.

In order that the preparation may be of the proper strength, it is necessary that the tincture should have been made with the best Jamaica ginger. The syrup of ginger is much used as a warm stomachic addition to tonic and purgative infusions or mixtures, and to impart flavour to drinks, particularly to carbonic acid water. The dose is a fluidrachm or more.

Off. Prep. Trochisci Zingiberis, *U. S.* W.

TINCTURÆ.

Tinctures.

Tinctures, in the pharmaceutical sense of the term, are solutions of medicinal substances in alcohol or diluted alcohol, prepared by maceration, digestion, or percolation. Solutions in spirit of ammonia and ethereal spirit are embraced under the same denomination, but are severally distinguished by the titles of *ammoniated tinctures* and *ethereal tinctures*. The advantages of alcohol as a menstruum are, that it dissolves principles which are sparingly or not at all soluble in water, and contributes to their preservation when dissolved; while it leaves behind some inert substances which are dissolved by water. In no instance, however, is absolute alcohol employed. The U. S. Pharmacopœia directs it of the sp. gr. 0·835; the British, 0·838. When of these densities it contains water, and is capable of dissolving more or less of substances which are insoluble in anhydrous alcohol; while its solvent power, in relation to bodies soluble in that fluid, is sufficient for all practical purposes. Diluted alcohol or proof spirit is often preferable to officinal alcohol; as it is capable of extracting a larger proportion of those active principles of plants which require an aqueous menstruum, at the same time that it is strong enough, in most instances, to prevent spontaneous decomposition, and has the advantages of being cheaper and less stimulating.* The diluted alcohol of the different Pharmacopœias is not of the same strength; that of the United States consisting of equal measures of officinal alcohol and water, and having the sp. gr. 0·941; while that of the British, called *Spiritus Tenuior* or Proof Spirit, has the sp. gr. 0·920. The difference, however, is not very material. Alcohol or rectified spirit is preferred as the solvent, when the substance to be extracted or dissolved is nearly or quite insoluble in water, as in the instances of the resins, guaiac, camphor, and the essential oils. The presence of water is here injurious, not only by diluting the menstruum, but by exercising an affinity for the alcohol which interferes with its solvent power. Thus, water, added to an alcoholic solution of one of these bodies, produces a precipitate by abstracting the alcohol from it. Diluted alcohol or proof spirit is employed, when the substance is soluble both in alcohol and water; or when one or more of the ingredients are soluble in the one fluid, and one or more in the other, as in the case of those vegetables which contain extractive or tannin, or the native salts of the organic alkalies, or gum united with resin or essential oil. As these include the greater number of medicines from which tinctures are prepared, diluted alcohol is most frequently used.

In the preparation of the tinctures, the medicine should be in the dry state, and properly comminuted by being bruised, sliced, or pulverized. It is usually better in the condition of a coarse than of a very fine powder; as in the latter it is apt to agglutinate, and thus present an impediment to the penetration of the menstruum. When several substances differing in solubility are employed, they should be added successively to the spirit, those least soluble first, those most so last; as otherwise the menstruum might become saturated with the ingredient for which it has the strongest affinity, and thus be rendered incapable of dissolving a due proportion of the others.

Until recently, tinctures have been universally prepared by maceration or digestion. The Edinburgh College directed digestion to be continued usually for seven days. Our own Pharmacopœia formerly directed maceration at ordinary temperatures, and extended the period to two weeks. The latter plan was preferable, as it was more convenient and equally effectual, the lower temper-

* Mr. Wm. Bastick, in a communication to the Pharmaceutical Journal and Transactions, states, as the result of his experience, that most of the tinctures prepared with proof spirit or diluted alcohol undergo deterioration by time, in consequence of acetous fermentation taking place in the alcoholic fluid. The tinctures most prone to this change are those of senna, rhubarb, columbo, henbane, digitalis, bark, hops, aloes, and the compound tincture of cinnamon. The best preventive is to keep them in full and well-closed bottles, at a low temperature. (*Am. Journ. of Pharm.*, xx. 47.)

ature being compensated by the longer maceration. In several instances in which maceration is ordered in our Pharmacopœia, it is still continued for two weeks; but the period is very properly altered to suit the character of the substance acted on, being sometimes shortened to a week when the medicine readily yields its virtues to the menstruum, and sometimes continued no longer than is necessary for its solution, when it is wholly soluble, as in the tinctures of iodine and tolu. When circumstances require that the tincture should be speedily prepared, digestion may be resorted to. Care should always be taken to keep the vessels well stopped, in order to prevent the evaporation of the alcohol. The materials should be frequently shaken during the digestion or maceration; and this caution is especially necessary when the substance acted on is in the state of powder. The tincture should not be used till the maceration is completed; when it should be separated from the dregs either by simply filtering it through paper, or, when force is requisite, by first expressing it through linen, and subsequently filtering.

The plan of preparing tinctures by percolation has recently been extensively adopted; and has been found to answer well when skilfully executed. In the U. S. Pharmacopœia of 1850, and in the late Ed. Pharmacopœia, this mode of preparation was given as an alternative in numerous instances; and would probably have been exclusively recommended in some, except for its liability to fail in inexperienced hands. In the present edition of our national standard, percolation has been adopted as the rule; maceration being directed in a few instances in which it was deemed preferable, and the alternative expressly allowed only in a single tincture, that, namely, of aloes and myrrh. The British Pharmacopœia, preferring maceration or digestion in several instances, has adopted percolation as a general rule; but, as if unprepared to trust this process alone, has combined with it a preliminary maceration of forty-eight hours, and a final expression, so as to separate the last remains of the tincture from the dregs. Perhaps these modifications may be desirable in instances where the operator is insufficiently skilful; but percolation, properly managed, is of itself adequate to all the desired purposes, even to the removal of almost the last drop of impregnated menstruum from the dregs; and, in our Pharmacopœia, it is taken for granted that the apothecary has acquired the requisite skill. Where the operator cannot trust himself in this respect, it would be better to recur to the old method of maceration for two weeks. The reader will find rules for the proper management of the process of percolation at *pages* 931 and 942. It has been objected to this process that it yields tinctures of variable strength, according to the skill with which it is conducted; but, from numerous experiments performed, in reference to this point, by M. H. Buignet, of Paris, it appears that the tinctures made by percolation are quite as equable in strength as those prepared by maceration, while they uniformly contain more of the soluble matter of the drug in proportion to the quantity of menstruum. The same writer states that he has constantly found three parts of alcohol, used in this method, to one of the material acted on, sufficient almost wholly to exhaust drugs of their soluble matter. He has derived no advantage from the preliminary maceration usually practised. (*Journ. de Pharm.*, Sept. 1857, p. 172.) M. Personne, however, has inferred, from his own observation, that five parts of alcohol are required by most substances. (*Ibid.*, Avril, 1860, p. 274.) Our own Pharmacopœia generally exceeds this. It has been contended in opposition to percolation, applied to the preparation of tinctures, that the menstruum in this process is apt to load itself with substances, which, after the preparation of the tincture, are deposited, carrying down with them more or less of the active matter; but M. Vauflart asserts that more than twenty years of observation has demonstrated to him, that tinctures by displacement, properly filtered, deposit no more than, at the end of a certain period, those deposit prepared by maceration. (*Ibid.*, Avril, 1862, p. 262.) Besides, upon the same authority, this tendency to deposition may be easily obviated by mixing all the liquids proceeding from the percolation, and allowing the mixture to stand for a day before filter-

ing. The tinctures thus obtained are, he states, richer than those furnished by ordinary maceration, and time produces in them only insignificant changes. (*Journ. de Pharm.*, 4e sér., iv. 411, A.D. 1866.) Finally, all agree that the percolated tinctures are apt to contain more of the soluble matter of the drug; and the objections resolve themselves altogether into a question of skill on the part of the operator.

Another mode of exhausting medicines by spirit has been proposed by Dr. H. Burton. It consists in suspending in the solvent, immediately under its surface, the solid matter contained loosely in a bag. The liquid in contact with the bag, becoming heavier by impregnation with the matters dissolved, sinks to the bottom; its place is supplied with a fresh portion, which in its turn sinks; and thus a current is established, which continues until the solid substance is exhausted, or the liquid saturated. During the maceration, the bag should be occasionally raised above the surface of the liquor in the bottle, allowed to drain, and then again immersed. It is asserted that the period of maceration is much shortened in this way. (*Lond. Med. Gaz.*, Aug. 30, 1844.)*

Tinctures, prepared by adding alcohol to the expressed juices of plants, have been long in use on the Continent of Europe, and have been brought into notice in Great Britain. They are sometimes called in England *preserved vegetable juices*. The tinctures of some of the narcotic plants might no doubt be advantageously prepared in this way, as those of conium, hyoscyamus, and belladonna. Mr. Squire and Mr. Bentley have paid particular attention to these preparations. According to Mr. Squire, the leaves only of the plants should be used, and, in the case of biennial plants, those exclusively of the second year; and they should be preferably collected when the plant is in full flower. Mr. Bentley recommends the following mode of preparation. To the expressed juice, after it has stood for 24 hours, and deposited its feculent matter, alcohol of 0·838 is to be added in the proportion of one part by measure to four of the juice; and, after another period of 24 hours, the liquor is to be filtered. This proportion of alcohol has been found sufficient for the preservation of the juice, while it causes the precipitation of the suspended mucilaginous matter. But, though these preserved juices are often energetic, yet it is obvious that tinctures prepared from the fresh plant must be still more so; as they contain necessarily not only the soluble active matter of the juice, but that also which, when the juice is expressed, is left in the solid residue of the plant. Three of them have been introduced into the British Pharmacopœia, under the name simply of *Succi* or *Juices*.

Tinctures should be kept in bottles accurately stopped, in order to prevent evaporation, which might, in some instances, be attended with serious inconvenience, by increasing their strength beyond the officinal standard.

* For this mode of preparing tinctures, Mr. Samuel Gale has proposed the use of a cylindrical stoneware vessel, with a diaphragm capable of being supported at different heights by projections from the inner surface of the jar, with corresponding notches in the diaphragm, to permit its easy passage to the lower ledges. The material is to be placed upon the diaphragm, and kept covered with the menstruum. (See *Am. Journ. of Pharm.*, xxii. 381, from *Pharm. Journ.*) The infusion jars described and figured in a note in *page* 1224 may be used also for preparing tinctures by maceration.

The following is a table showing the mode in which the tinctures of the medicines enumerated should be prepared, in the opinion of the Society of Pharmacy of Paris, as given at their session on June 25, 1862.

By Percolation with alcohol of 60°.	*By Percolation with alcohol of* 80°.	*By Maceration with alcohol of* 60°.	*By Maceration with alcohol of* 80°.	*By Maceration with alcohol of* 90°.
Belladonna.	Valerian.	Aloes.	Castor.	Assafetida.
Conium.	Cinnamon.	Arnica flowers.	Columbo.	Balsam of Peru.
Hyoscyamus.	Red Cinchona.	Catechu.	Colchicum Seed.	Balsam of Tolu.
Stramonium.	Yellow Cinchona.	Colchicum bulbs.	Cloves.	Benzoin.
Digitalis.		Gentian.	Ginger.	Ammoniac.
Quassia.		Ipecacuanha.	Jalap.	Myrrh.
Pale Cinchona.		Musk.	Nux Vomica.	Scammony.
Rhatany.		Rhubarb.	Saffron.	
Senna.		Squill.	Vanilla.	

Medicines are most conveniently administered in tincture, which act in small doses; as the proportion of alcohol in which they are dissolved is insufficient to produce an appreciable effect. Those which must be given in large doses should be cautiously employed in this form, lest the injury done by the menstruum should more than counterbalance their beneficial operation. This remark is particularly applicable to chronic cases, in which the use of tinctures is apt to lead to the formation of habits of intemperance. The tinctures of the weaker medicines are more frequently given as adjuvants of other remedies than with the view of obtaining their own full effects upon the system.

The following general directions are given in the *U. S. Pharmacopœia.*

"When tinctures are prepared by percolation, great care should be taken to observe the directions given at page 3 [*page* 942 of this Dispensatory], so that the substances treated may be, as far as possible, exhausted of their soluble principles, and a perfectly clear tincture obtained. When prepared by maceration, they require to be frequently shaken during the process, which should be conducted in glass bottles well stopped."

The officinal Preparations formerly belonging to this class, which have been omitted in the present U. S. and Br. Pharmacopœias, are *Tinctura Ammoniæ Composita*, Lond.; *Essentia Carui*, Dub.; *Tinct. Cassiæ*, Ed.; *Tinct. Castorei Ammoniata*, Ed.; *Tinct. Cinchonæ Pallidæ*, Lond.; *Tinct. Cinnamomi Comp.*, U. S., Lond., Ed., Dub.; *Tinct. Colchici Comp.*, Lond.; *Tinct. Cuspariæ*, Ed.; *Essentia Fœniculi*, Dub.; *Tinct. Lactucarii*, Ed.; *Tinct. Matico*, Dub.; *Essentia Myristicæ Moschatæ*, Dub.; *Essentia Pulegii*, Dub.; *Essentia Pimentæ*, Dub.; *Tinct. Quassiæ Comp.*, Ed.; *Tinct. Rhei Comp.*, Lond., Dub.; *Tinct. Rhei et Gentianæ*, U. S., Ed.; *Essentia Rosmarini*, Dub.; *Tinct. Sennæ Comp.*, Ed.; and *Tinct. Sennæ et Jalapæ*, U. S. The *Tinct. Camphoræ*, U. S., Ed., Dub., the *Tinct. Olei Menthæ Piperitæ*, U. S., and the *Tinct. Olei Menthæ Viridis*, U. S., have been transferred to the Spirits with changed names, and some change of strength; while the *Tinct. Saponis Camphorata*, U. S., has been placed among the *Liniments* with the altered name of *Linimentum Saponis.*

TINCTURA ACONITI FOLII. *U. S.* *Tincture of Aconite Leaf.*

"Take of Aconite Leaf, recently dried and in fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it firmly in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of Tincture are obtained." *U. S.*

This is a good preparation of aconite when made from the recently dried leaves, and may be given in the dose of twenty or thirty drops. A saturated tincture prepared from the root is now more used. It is much stronger than the tincture of the leaves, and great care should be taken not to confound them in prescription. (See *Tinctura Aconiti Radicis.*) W.

TINCTURA ACONITI RADICIS. *U. S.* TINCTURA ACONITI. *Br.* *Tincture of Aconite Root.*

"Take of Aconite Root, in fine powder, *twelve troyounces;* Alcohol *a sufficient quantity.* Moisten the powder with six fluidounces of Alcohol, pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it until two pints of tincture are obtained." *U. S.*

"Take of Aconite Root, in coarse powder, *two ounces and a half* [avoirdupois]; Rectified Spirit *one pint* [Imperial measure]. Macerate the Aconite Root for forty-eight hours, in *fifteen* [*fluid*]*ounces* of the Spirit, in a closed vessel, agitating occasionally; then transfer to a percolator, and, when the fluid ceases to pass, continue the percolation with the remaining five [fluid]ounces of Spirit. Afterwards subject the contents of the percolator to pressure, filter the product, mix the liquids, and add sufficient Rectified Spirit to make one pint [Imp. meas.]." *Br.*

The tincture of the U. S. Pharmacopœia has three times the strength of the British. It is much stronger than that of the leaves, and too much caution cannot be observed to avoid mistaking one for the other. In preparing it, each step

of the process must be carefully attended to. The root should be thoroughly comminuted, and very carefully packed in the percolator, and the displacing menstruum very gradually added. As annoyance is often occasioned in powdering aconite by the irritating dust which is apt to rise, it is best prepared by grinding in a mill; and, if the operator does not happen to have such an instrument at his command, Prof. Procter suggests that sufficient alcohol should be added to the root in a mortar, to prevent the rising of the dust. (*Am. Journ. of Pharm.*, March, 1861, p. 103.) The dose to begin with is from five to ten drops, which may be repeated three times a day, and gradually increased, if necessary, until its peculiar effects are experienced. That of the British tincture is three times as much. We would here repeat the caution, already given when treating of Aconite in the first part of this work, that physicians should be careful, in prescribing either of the tinctures of aconite, to give the whole name of the one they intend, as otherwise serious consequences may ensue.* W.

TINCTURA ALOËS. *U. S.*, *Br.* *Tincture of Aloes.*

"Take of Socotrine Aloes, in fine powder, *a troyounce;* Liquorice [extract] *three troyounces;* Alcohol *half a pint;* Distilled Water *a pint and a half.* Macerate for fourteen days, and filter through paper." *U. S.*

"Take of Socotrine Aloes, in coarse powder, *half an ounce* [avoirdupois]; Extract of Liquorice *one ounce and a half* [avoird.]; Proof Spirit *a sufficiency.* Macerate the Aloes and Extract of Liquorice in fifteen fluidounces of the Spirit for seven days, in a closed vessel, with occasional agitation, then filter, and add sufficient Proof Spirit to make one pint [Imp. meas.]." *Br.*

The original tincture of aloes of the U. S. Pharmacopœia was prepared with the officinal diluted alcohol, without the addition of water. At present it is little more than an infusion, with the addition of sufficient alcohol to prevent spontaneous decomposition. But, while this change has been made in the U. S. formula, so as to produce conformity with the British Colleges, in the late construction of the British Pharmacopœia, their old formula has been abandoned, and the one forsaken by us adopted. The liquorice is in both formulas added to cover the taste of the aloes; but it answers the end imperfectly, and the preparation, on account of its unpleasant bitterness, is little used, aloes being generally administered in the form of pill. M. Menière says of the tincture of aloes that it deposits crystals of aloïn, which adhere to the sides of the bottle, and in the upper part of it a yellow resinous matter. (*Journ. de Pharm.*, Avril, 1861, p. 289.) The dose as a purgative is from half a fluidounce to a fluidounce and a half, as a laxative from one to two fluidrachms. Tincture of aloes is highly recommended by M. Delioux as a local remedy in old atonic ulcers, bed-sores, and suppurating wounds, to which it may be applied on lint. (*Pharm. Journ.*, July, 1864, p. 38.) W.

TINCTURA ALOËS ET MYRRHÆ. *U. S.* TINCTURA ALOES COMPOSITA. *Lond.* *Tincture of Aloes and Myrrh.*

"Take of Socotrine Aloes, in moderately fine powder, Myrrh, in moderately fine powder, each, *three troyounces;* Saffron, in moderately coarse powder, *a troyounce;* Alcohol *a sufficient quantity.* Mix the powders, and, having moistened the mixture with two fluidounces of Alcohol, pack it moderately in a conical percolator, and gradually pour Alcohol upon it until two pints of tincture are

* The tincture proposed by Dr. Fleming should always be expressly designated when prescribed. It is considerably stronger than the officinal; and several deaths have occurred from the use of it. The following is his formula. Take of the root, carefully dried and finely powdered, *sixteen (troy)ounces;* Alcohol *sixteen fluidounces.* Macerate for four days, put into a percolator, and add alcohol until twenty-four fluidounces are obtained. Not more than five drops of this should be given as a commencing dose, to be increased till its peculiar effects are experienced.

Prof. Procter proposes, in order to obtain a strong tincture, and at the same time completely to exhaust the root, to continue the percolation until 50 or 100 per cent more of the filtered liquor is obtained than is wanted, and then to reduce this to the proper measure by means of a water-bath. (*Note to the eleventh edition.*)

obtained. This Tincture may also be prepared by macerating the powders with two pints of Alcohol for fourteen days, and filtering through paper." *U. S.*

This tincture is a modification of the *elixir proprietatis* of Paracelsus. The saffron, which has been retained in compliance with former prejudices, can add little to the efficacy of the preparation; and, being very expensive, has with great propriety been much reduced in the U. S. formula. It serves, however, to impart a richness to the tincture, the want of which might be considered a defect by those accustomed to its use.

The tincture is purgative, tonic, and emmenagogue, and is considerably employed in chlorosis, and other disordered states of health in females, connected with suppressed, retained, or deficient menstruation, and with a constipated state of bowels. It may also be used as a stomachic laxative in cold, languid habits, independently of menstrual disorder. The dose is from one to two fluidrachms. W.

TINCTURA ARNICÆ. *U. S., Br. Tincture of Arnica.*

"Take of Arnica [flowers] *six troyounces;* Alcohol *a pint and a half;* Water *half a pint;* Diluted Alcohol *a sufficient quantity.* Mix the Alcohol and Water, and, having moistened the Arnica slightly with the mixture, bruise it thoroughly in a mortar. Then pack it firmly in a cylindrical percolator, and pour upon it, first the remainder of the mixture, and afterwards sufficient Diluted Alcohol to make the tincture measure two pints." *U. S.*

The *British Pharmacopœia* gives directions for preparing this Tincture from *an avoirdupois ounce* of Arnica Root, in coarse powder, and *an Imperial pint* of Rectified Spirit, precisely the same as those for preparing Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

In the article upon Arnica in *Part* I. (p. 148), it is stated that arnica is poisonous in overdoses, and a case is referred to in which death was attributed to it, though somewhat doubtfully. In the *Lancet* for Nov. 19, 1864 (*page* 570), Mr. H. Bertin, house surgeon of St. Mary's Hospital, gives the details of a case, in which a middle-aged man was brought into the hospital ten hours after having taken by mistake an ounce of tincture of arnica, intended for use as a lotion. He was in a state approaching collapse, with sunken and glassy eyes, dilated and insensible pupils, pulse fluttering and over a hundred, skin cold but dry, low and wiry voice, and severe pain in the epigastrium, which was the first striking symptom that he had experienced, and had come on upon awaking from sleep, about eight hours after he swallowed the poison. The mind was apparently clear. Though in great danger, he recovered, under the use of opium and brandy with external heat.

Either alone, or diluted with water, soap liniment, &c., tincture of arnica is often applied popularly to bruises, sprains, tumours, and local rheumatic pains, under the impression that it has extraordinary healing powers. It probably acts favourably in some instances as a gentle irritant. If given internally, the dose would be from thirty minims to two fluidrachms. W.

TINCTURA ASSAFŒTIDÆ. *U. S., Br. Tincture of Assafetida.*

"Take of Assafetida, bruised, *four troyounces;* Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U. S.*

"Take of Assafœtida, in small fragments, *two ounces and a half* [avoirdupois]; Rectified Spirit *a sufficiency.* Macerate the Assafœtida in fifteen fluidounces of the Spirit for seven days in a closed vessel, with occasional agitation, then filter, and add sufficient Rectified Spirit to make one pint [Imperial measure]." *Br.*

This tincture becomes milky on the addition of water, in consequence of the separation of the resin. It possesses all the virtues of assafetida. The dose is from thirty minims to a fluidrachm. W.

TINCTURA AURANTII. *Br. Tincture of Orange Peel.*

"Take of Bitter Orange Peel, cut small and bruised, *two ounces* [avoirdupois]; Proof Spirit *one pint* [Imperial measure]. Macerate for seven days in

a closed vessel, with occasional agitation, then strain, press, and filter, and add sufficient Proof Spirit to make one pint [Imp. meas.]." *Br.*

It is the peel of the Seville orange which is directed in this process; and the outer part only should be used, the inner whitish portion being inert. The tincture of orange peel is employed as a grateful addition to infusions, decoctions, and mixtures. The dose is one or two fluidrachms.

Off. Prep. Mistura Ferri Aromatica, *Br.;* Syrupus Aurantii, *Br.;* Tinctura Quiniæ, *Br.* W.

TINCTURA BELLADONNÆ. *U. S*, *Br. Tincture of Belladonna.*

"Take of Belladonna Leaf, recently dried and in fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it firmly in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* directs this Tincture to be prepared from *one avoirdupois ounce* of Belladonna Leaves, in coarse powder, and *one Imperial pint* of Proof Spirit, in the same manner precisely as the Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.) "This Tincture has about half the strength of Tinctura Belladonnæ, *Lond., Dub.*" *Br.*

According to Menière, this tincture deposits on standing a gray pulverulent substance, starch and gum, and cubical crystals of an undetermined character. (*Journ. de Pharm.*, Avril, 1861, p. 289.) The U. S. tincture is an efficient preparation when made from the recently dried leaves; but the imported leaves are of very uncertain strength, and a tincture prepared from them is to be less relied upon than the extract. The dose is from fifteen to thirty drops. That of the British tincture is at least twice as much. W.

TINCTURA BENZOINI COMPOSITA. *U. S.*, *Br. Compound Tincture of Benzoin.*

"Take of Benzoin, in coarse powder, *three troyounces;* Socotrine Aloes, in coarse powder, *half a troyounce;* Storax *two troyounces;* Balsam of Tolu *a troyounce;* Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U. S.*

"Take of Benzoin, in coarse powder, *two ounces* [avoirdupois]; Prepared Storax *one ounce and a half* [avoird.]; Balsam of Tolu *half an ounce* [avoird.]; Socotrine Aloes *one hundred and sixty grains;* Rectified Spirit *one pint* [Imperial measure]. Macerate for seven days in a closed vessel, with occasional agitation, then filter, and add sufficient Rectified Spirit, if required, to make one pint [Imp. meas.]" *Br.*

This tincture is a stimulating expectorant, occasionally used in chronic catarrhal affections. It has been recommended also in chronic dysentery, with a view to its alterative action on the ulcerated surface of the colon; but it is most employed as a local application to indolent ulcers, chapped nipples, &c. It has been found useful injected into the nostrils in obstinate epistaxis. (*Braithwaite*, no. 37, p. 58.) It is the *balsamum traumaticum* of the older Pharmacopœias, and may be considered as a simplified form of certain complex compositions, such as *baume de commandeur*, *Wade's balsam*, *Friar's balsam*, *Jesuits' drops*, *&c.*, which were formerly in repute, and are still esteemed among the vulgar as pectorals and vulneraries. It is also an ingredient in *Turlington's balsam*, which is a popular remedy in this country for the same purposes.* It is scarcely necessary to state that the application of these preparations to fresh wounds must frequently prove injurious, by inducing too much inflammation, and thus preventing union by the first intention. The compound tincture of benzoin is decomposed by water. The dose is from thirty minims to two fluidrachms. A va-

* The following is the formula for *Turlington's balsam* adopted by the Philadelphia College of Pharmacy. "Take of Alcohol Oviij, Benzoin ℥xij, Liquid Storax ℥iv, Socotrine Aloes ℥j, Peruvian Balsam ℥ij, Myrrh ℥j, Angelica Root ℥ss, Balsam of Tolu ℥iv, Extract of Liquorice Root ℥iv. Digest for ten days, and strain." (*Journ. of the Phil. Col. of Pharm.*, v. 28.)

riety of *court plaster* is made by applying to black silk, by means of a brush, first a solution of isinglass, and afterwards an alcoholic solution of benzoin. W.

TINCTURA BUCHU. *Br. Tincture of Buchu.*

This Tincture is directed, in the *British Pharmacopœia*, to be prepared from *two and a half avoirdupois ounces* of Buchu Leaves, in coarse powder, and *one Imperial pint* of Proof Spirit, in the same manner precisely as Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This tincture has the virtues of buchu leaves, and may be given in the dose of from one to four fluidrachms, either simply diluted with water, or as an addition to the infusion of the leaves. W.

TINCTURA CALUMBÆ. *U. S., Br. Tincture of Columbo. Tincture of Calumba Br.*

"Take of Columbo, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, transfer it to a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* directs this Tincture to be prepared from *two and a half avoirdupois ounces* of Calumba Root, cut small, and *one Imperial pint* of Proof Spirit, in the same manner precisely as directed for the Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

The tincture of columbo of the U. S. Pharmacopœia was, with great propriety, considerably increased in strength at the revision of 1840. The larger the proportion of the tonic is to the alcohol in these bitter tinctures, the better are they calculated to meet the indications for which they are usually prescribed. When the proportion is very small, the tonic power of the bitter is lost in the stimulant influence of the alcohol. Mr. Jos. Ince recommends that the tincture should be prepared from the root as found in the shops, without further slicing or powdering it. Made as he proposes, the tincture is clear and bright; while if the powdered root is used it will be very turbid, even after filtration. (*Pharm. Journ.*, xiv. 491.) The tincture of columbo may be added to tonic infusions or decoctions, to increase their stimulant power; but, like all the other bitter tinctures, should be used with caution. The dose is from one to four fluidrachms. W.

TINCTURA CANNABIS. *U. S.* TINCTURA CANNABIS INDICÆ. *Br. Tincture of Hemp. Tincture of Indian Hemp.*

"Take of Purified Extract of Hemp *three hundred and sixty grains;* Alcohol *a pint.* Dissolve the Extract in the Alcohol, and filter through paper." *U. S*

"Take of Extract of Indian Hemp *one ounce* [avoirdupois]; Rectified Spirit *one pint* [Imperial measure]. Dissolve the Extract of Hemp in the Spirit." *Br.*

The American reader must take care not to confound the Indian Hemp, here alluded to, with Apocynum Cannabinum, known by the same name in this country. The dose, equivalent to a grain of the extract, is twenty-two minims or about forty drops, to be gradually increased till its effects are experienced. W.

TINCTURA CANTHARIDIS. *U. S., Br. Tincture of Cantharides. Tincture of Spanish Flies.*

"Take of Cantharides, in fine powder, *a troyounce;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with half a fluidounce of Diluted Alcohol, pack it in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

"Take of Cantharides, in coarse powder, *one-quarter of an ounce* [avoirdupois]; Proof Spirit *one pint* [Imperial measure]. Macerate for seven days in a closed vessel, with occasional agitation, strain, press, filter, and add sufficient Proof Spirit to make one pint. [Imp. meas.]." *Br.*

This tincture is one of the most convenient forms for the internal use of Spanish flies, the virtues of which it possesses to their full extent. (See *Cantharis.*) When long kept it deposits fatty matter, cantharidin in rhomboidal tables, and other crystals of a quite different form. (Menière, *Journ. de Pharm.*,

Avril, 1861, p. 289.) It is occasionally employed externally as a rubefacient but its liability to vesicate should be taken into consideration. The British tincture is too feeble; containing the virtues of only 0·68 of a grain of cantharides in a fluidrachm. The dose of the U. S. tincture is from twenty drops to a fluidrachm, repeated three or four times a day. W.

TINCTURA CAPSICI. *U. S., Br. Tincture of Capsicum. Tincture of Cayenne Pepper.*

"Take of Capsicum, in fine powder, *a troyounce;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with half a fluidounce of Diluted Alcohol, pack it in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* directs this Tincture to be prepared from *three-quarters of an avoirdupois ounce* of bruised Capsicum Fruit, and *one Imperial pint* of Rectified Spirit, in the same manner precisely as directed for the Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This preparation of capsicum is a useful stimulant in very low states of the system with gastric insensibility, as in malignant scarlet and typhus fevers, and in the cases of drunkards. It may also be used as a gargle, diluted with rose-water or some mucilaginous fluid. (See *Capsicum.*) Applied by means of a camel's-hair pencil to the relaxed uvula, it sometimes produces contraction, and relieves prolapsus of that part. The dose is one or two fluidrachms. W.

TINCTURA CARDAMOMI. *U.S. Tincture of Cardamom.*

"Take of Cardamom, in fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

This tincture is an agreeable aromatic, and may be advantageously added to tonic and purgative infusions. The dose is one or two fluidrachms. W.

TINCTURA CARDAMOMI COMPOSITA. *U.S., Br. Compound Tincture of Cardamom.*

"Take of Cardamom, in moderately fine powder, *three hundred and sixty grains;* Caraway, in moderately fine powder, *one hundred and twenty grains;* Cinnamon, in moderately fine powder, *three hundred grains;* Cochineal, in moderately fine powder, *sixty grains;* Clarified Honey *two troyounces;* Diluted Alcohol *a sufficient quantity.* Mix the powders, and, having moistened the mixture with half a fluidounce of Diluted Alcohol, pack it in a cylindrical percolator, and gradually pour Diluted Alcohol upon it until two pints and six fluidounces of tincture are obtained. Lastly, mix this with the Clarified Honey, and filter through paper." *U. S.*

The *British Pharmacopœia* takes of Cardamom Seeds, freed from the pericarps and bruised, and Caraway Fruit, bruised, each, *a quarter of an avoirdupois ounce;* Raisins, freed from their seeds, *two avoirdupois ounces;* Cinnamon Bark, bruised, *half an avoirdupois ounce;* Cochineal, in powder, *sixty grains;* and Proof Spirit *one Imperial pint;* and directs that the tincture should be prepared in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This is a very agreeable aromatic tincture, occasionally used as a carminative in the dose of one or two fluidrachms, but more frequently as an addition to mixtures, infusions, &c., which it renders pleasant to the taste, and acceptable to the stomach. The substitution of honey in the present U. S. formula for the raisins in that of 1850, may be regarded as an improvement, at least in a pharmaceutical point of view, as it facilitates the process, and, considering the unequal quality of raisins, gives more precision to the result.

Off. Prep. Decoctum Aloes Compositum, *Br.;* Mistura Ferri Aromatica, *Br.;* Mistura Sennæ Composita, *Br.;* Tinctura Chloroformi Composita, *Br.* W.

TINCTURA CASCARILLÆ. *Br. Tincture of Cascarilla.*

The *British Pharmacopœia* directs this Tincture to be prepared from *two and a half avoirdupois ounces* of bruised Cascarilla, and *one Imperial pint* of Proof Spirit, in the same manner precisely as directed for the Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This tincture has the properties of cascarilla, but is seldom if ever used in this country. The dose is from thirty minims to two fluidrachms. W.

TINCTURA CASTOREI. *U. S., Br. Tincture of Castor.*

"Take of Castor, bruised, *two troyounces;* Alcohol *two pints.* Macerate for seven days, express, and filter through paper." *U. S.*

"Take of Castor, in coarse powder, *one ounce* [avoirdupois]; Rectified Spirit *one pint* [Imperial measure]. Macerate for seven days in a closed vessel, with occasional agitation; strain, press, filter, and add sufficient Rectified Spirit to make one pint [Imp. meas.]." *Br.*

As castor yields little if any of its virtues to water, alcohol is a better solvent than proof spirit. It is said also to form a more grateful preparation. The Russian castor should always be preferred when attainable. It deposits on standing a yellow organic substance, which, when moistened with water, exhibits animalcules under the microscope. (*Menière.*) This tincture is employed for the same purposes as castor in substance. The dose is from thirty minims to two fluidrachms. W.

TINCTURA CATECHU. *U. S., Br. Tincture of Catechu.*

"Take of Catechu, in moderately coarse powder, *three troyounces;* Cinnamon, in moderately coarse powder, *two troyounces;* Diluted Alcohol *a sufficient quantity.* Mix the powders, and, having moistened the mixture with a fluidounce of Diluted Alcohol, pack it in a conical glass percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

"Take of Pale Catechu, in coarse powder, *two and a half ounces* [avoirdupois]; Cinnamon Bark, bruised, *one ounce* [avoird.]; Proof Spirit *one pint* [Imperial measure]. Macerate for seven days in a closed vessel, with occasional agitation; strain, press, filter, and add sufficient proof spirit to make one pint [Imp. meas.]." *Br.*

This is a grateful astringent tincture, useful in all cases to which catechu is applicable, and in which small quantities of spirit are not objectionable. It may often be advantageously added to cretaceous mixtures in diarrhœa. The dose is from thirty minims to three fluidrachms, which may be given with sweetened water or some mucilaginous liquid, or in port wine when this is not contraindicated. Like the tincture of kino, this is said sometimes to gelatinize when kept. In this state it is unfit for use. W.

TINCTURA CHIRATÆ. *Br. Tincture of Chiretta.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Chiretta, cut small and bruised, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This is a tonic tincture, and may be given in the dose of one or two fluidrachms, three or four times a day. W.

TINCTURA CHLOROFORMI COMPOSITA. *Br. Compound Tincture of Chloroform.*

"Take of Chloroform *two fluidounces;* Rectified Spirit *eight fluidounces:* Compound Tincture of Cardamoms *ten fluidounces.* Mix." *Br.*

A convenient form for the internal use of chloroform. The dose is from twenty minims to a fluidrachm diluted with water. W.

TINCTURA CINCHONÆ. *U. S.* TINCTURA CINCHONÆ FLAVÆ. *Br. Tincture of Cinchona. Tincture of Yellow Cinchona. Tincture of Peruvian Bark.*

"Take of Yellow Cinchona, in moderately fine powder, *six troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces

of Diluted Alcohol, pack it firmly in a glass percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *four avoirdupois ounces* of Yellow Cinchona Bark, in moderately fine powder, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This tincture is very properly made with a large proportion of bark; as, in the bitter tinctures, it is important that the alcohol should bear as small a proportion to the tonic principle as possible. Even when strongest, however, it cannot, in ordinary cases, be given in doses sufficiently large to obtain the full effect of the bark, without stimulating too highly. A deposit is apt to form in the tincture when kept, consisting in chief of cinchonic red holding probably a portion of the alkaloids in combination. This was found by Mr. J. Adams to be perfectly dissolved by heat, though it uniformly reappeared on the cooling of the tincture. The addition of diluted sulphuric acid did not cause its solution; and, even though it was removed by filtering the tincture, the deposition was afterward renewed. (*Pharm. Journ.*, April, 1868, p. 470.) In reference to a mode of in some measure obviating this tendency to deposition, the reader is referred to the statements of M. Vauflart on the subject of deposition in the tinctures prepared by percolation (see *page* 1446). Mr. A. B. Taylor, in experimenting on this subject, prepared a tincture in which the menstruum consisted of two parts of alcohol, one part of water, and one of glycerin, and which was kept three months without undergoing deposition. (*Am. Journ. of Pharm.*, Jan. 1865, p. 50.) This suggests the addition of glycerin to the officinal formula, should further observation prove the action of this solvent to be permanent. Tincture of cinchona is used chiefly as an adjunct to the infusion or decoction of bark, or the solution of sulphate of quinia, to a dose of which it may be added in the quantity of from one to four fluidrachms. W.

TINCTURA CINCHONÆ COMPOSITA. *U. S.*, *Br.* *Compound Tincture of Cinchona.* *Compound Tincture of Peruvian Bark.*

"Take of Red Cinchona, in moderately fine powder, *four troyounces;* Bitter Orange Peel, in moderately fine powder, *three troyounces;* Serpentaria, in moderately fine powder, *three hundred and sixty grains;* Saffron, in moderately coarse powder, Red Saunders, in moderately fine powder, each, *one hundred and twenty grains;* Diluted Alcohol *a sufficient quantity.* Mix the powders, and, having moistened the mixture with four fluidounces of Diluted Alcohol, pack it firmly in a glass percolator, and gradually pour Diluted Alcohol upon it until two pints and a half of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes of Pale Cinchona Bark, in moderately fine powder, *two avoirdupois ounces*, Bitter-Orange Peel, cut small and bruised, *one avoirdupois ounce*, Serpentaria, bruised, *half an avoirdupois ounce*, Saffron *sixty grains*, Cochineal, in powder, *thirty grains*, and Proof Spirit *one Imperial pint;* and proceeds, with these ingredients, in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This is the preparation commonly known by the name of *Huxham's tincture of bark.* It is unfortunate that the British Council, following the London and Dublin Colleges, should have selected the feeblest of the officinal varieties of bark for this important tincture. The compound tincture of bark is an excellent stomachic cordial, and, though too feeble in the principles of cinchona to serve as a substitute for that tonic when its full effect is required, may be very usefully employed as an addition to the decoction or infusion, or to the salts of quinia, in low forms of fever, particularly in malignant intermittents and remittents. Huxham was in the habit of uniting with it the *elixir of vitriol*, the aromatic sulphuric acid of the Pharmacopœias. The dose is from one to four fluidrachms.

Under the name of *tinctura cinchonæ ferrata*, a preparation has been considerably employed in Philadelphia, for which the following formula is given by Mr. Samuel Simes, in the *Am. Journ. of Pharm.* (xxv. 402). With *one gallon* of the compound tincture of bark, *one ounce* of hydrated sesquioxide of

iron, dried at a temperature not exceeding 130° F., is digested, and the liquor filtered. The tannic acid is removed by the iron forming an insoluble tannate, which with the excess of oxide is separated by the filtration. In order not to lose any portion of the alkaloids which may adhere to the precipitate, this is to be well washed with boiling alcohol, the solution evaporated to dryness, the product dissolved in a little water acidulated with citric acid, and added to the filtered liquor. Lastly, *sixteen grains* of ammonio-citrate of iron are to be added to each fluidounce of the tincture. The doses is a fluidrachm.* W.

TINCTURA CINNAMOMI. *U. S.*, *Br.* *Tincture of Cinnamon.*

"Take of Cinnamon, in fine powder, *three troyounces;* Alcohol, Water, each, *a sufficient quantity.* Mix the Alcohol and Water in the proportion of two measures of the former to one of the latter. Then moisten the powder with a fluidounce of the mixture, pack it moderately in a conical percolator, and gradually pour the mixture upon it until two pints of filtered liquor are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Cinnamon Bark, in coarse powder, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This tincture has the aromatic and astringent properties of cinnamon, and may be used as an adjuvant to cretaceous mixtures, and astringent infusions or decoctions. The dose is from one to three or four fluidrachms.

Off. Prep. Infusum Digitalis, *U. S.* W.

TINCTURA COCCI. *Br.* *Tincture of Cochineal.*

"Take of Cochineal, in powder, *two ounces and a half* [avoirdupois]; Proof Spirit *one pint* [Imperial measure]. Macerate for seven days in a closed vessel, with occasional agitation; strain, press, filter, and add sufficient Proof Spirit to make one pint [Imp. meas.]." *Br.*

This is valued chiefly for imparting colour to liquid preparations. It may, however, be given internally in nervous affections in doses varying from twenty drops to a fluidrachm. W.

TINCTURA COLCHICI. *U. S.* TINCTURA COLCHICI SEMINUM, *Br.* *Tincture of Colchicum.* *Tincture of Colchicum Seeds.*

"Take of Colchicum Seed, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a cylindrical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of bruised Colchicum Seeds, and *one Imperial pint* of Proof Spirit, and proceeds

* Prof. Procter observes of this preparation that, in consequence of the cincho-tannic acid not being entirely removed by the dry sesquioxide, the preparation blackens upon standing. He proposes to substitute for the sesquioxide in a dried state, the same freshly precipitated, washed, and pressed strongly between folds of bibulous paper. (*Note to the eleventh edition.*)

Ferrated Elixir of Cinchona. A formula, by Mr. J. T. Shinn, for a preparation under this name, said to be in considerable use, will be found in the *American Journal of Pharmacy* for May, 1862 (p. 204).

Elixir Cinchonæ Flavæ. The following preparation has been much used in this city, and other parts of the U. States. The formula is that of Mr. A. B. Taylor, and is taken from the *Am. Journ. of Pharm.* (Jan. 1859, p. 18). "Take of Yellow Cinchona 4 *ounces;* Orange peel, recently dried, 2 *ounces;* Ceylon Cinnamon, Coriander seeds, each, *an ounce;* Anise, Caraway, Cardamom, Cochineal, each, 120 *grains;* Brandy *two pints and a half;* Syrup *two pints and a half;* Alcohol and Water, each, *a sufficient quantity.* Reduce the dry substances to moderately fine powder; mix the Brandy with its bulk of water; moisten the powder with four fluidounces of the mixture; and pack it in a conical percolator. Pour on the remainder of the liquid, and continue the percolation with a mixture of one part of alcohol to three parts of water, until six and a half pints of tincture are obtained; then add the syrup and mix them." This is an elegant aromatic tonic, extensively used as an adjuvant of other medicines, and alone as a mild stimulant aromatic tonic. The dose is from one to three fluidounces. (*Note to the twelfth edition.*)

in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

It was at one time supposed that the tincture was quite as effective made from the unbruised as the bruised seeds, and corresponding advice was given under Colchici Semen, in the first part of this work; but the opinion has been shown to be erroneous. (*Am. Journ. of Pharm.*, xxvi. 120.) Mr. Maisch recommends, as a convenient method of comminuting the seeds, to macerate them for two or three days in a portion of the menstruum, then to remove them and bruise them in a clean iron mortar; taking care that none of the menstruum or the seeds should be wasted. (*Ibid.*, xxviii. 514.)

This tincture possesses the active properties of colchicum, and may be given whenever that medicine is indicated; but the wine, which contains less alcohol, is generally preferred. The dose is from half a fluidrachm to two fluidrachms. The tincture is sometimes used as an embrocation in rheumatic, gouty, and neuralgic pains. W.

TINCTURA CONII. *U. S.*, *Br.* Tinctura Conii Fructus. *Br.* 1864. *Tincture of Hemlock. Tincture of Hemlock Fruit. Tincture of Conium.*

"Take of Hemlock [leaves], recently dried and in fine powder, *four troy-ounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it firmly in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of bruised Hemlock Fruit, and *one Imperial pint* of Proof Spirit, and proceeds as directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

The tincture of hemlock necessarily partakes of the uncertainty of the dried leaves from which it is prepared. There can be little doubt that the tincture of the British Pharmacopœia, made from the recent fruit, is the more efficient. A preparation, made by adding one measure of alcohol to three of the expressed juice, has been used in England under the name of *preserved juice of hemlock*, and has been adopted in the British Pharmacopœia with the title of *Succus Conii* or *Juice of Hemlock.* (See *page* 1420.) The Pharmacopœias have very properly excluded cardamom from the preparation; as it can have little influence upon its medical effects, and tends to obscure the odour which is an indication of the activity of the tincture. A strong odour of conia should be emitted by the tincture upon the addition of potassa. M. Menière states that it lets fall, on standing, a yellow miliary deposit, resembling drops of oil, the form of which is modified under pressure. The dose is from thirty minims to a fluidrachm.

From recent experiments by Dr. John Harley, of London, there is reason to think that the tincture is nearly inert, or at least not to be relied on as a remedial means in any ordinary dose. Of a tincture carefully prepared from the seeds, according to the British officinal directions, Dr. Harley took himself at different times quantities varying from half a fluidrachm to two fluidounces, beginning with the smaller and gradually increasing to the larger dose, without any observable effect except a stimulant action from the large quantities of alcohol. (*Pharm. Journ.*, Jan. 1867, p. 414.) As the same experimenter obtained very decided sedative effect from the juice of hemlock in comparatively small doses, and as the tincture gave decided evidences of containing conia, the only inference to be drawn from these experiments is that the sedative action of the conium is neutralized by the stimulation of the alcohol; and consequently that the tincture is not an eligible preparation. W.

TINCTURA CROCI. *Br. Tincture of Saffron.*

The *British Pharmacopœia* takes *one avoirdupois ounce* of Saffron, and *one Imperial pint* of Proof Spirit, and proceeds as directed for the Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This tincture possesses all the properties of saffron; but is of little other

use than to give colour to mixtures. The dose is from one to three fluidrachms. W.

TINCTURA CUBEBÆ. *U.S., Br. Tincture of Cubeb. Tincture of Cubebs.*

"Take of Cubeb, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Cubebs, in powder, and *one Imperial pint* of Rectified Spirit, and proceeds as directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This may be used as a carminative, and has been given with advantage in gonorrhœa in the advanced stages. The late London tincture was nearly three times as strong as the Dublin, and more than twice as strong as the U. S. tincture; but the preparation was dropped in the British Pharmacopœia; and being resumed in the present edition, was greatly reduced in strength, so as at present to be about equal in this respect with our own. The dose is from half a fluidrachm to two fluidrachms or more, the larger doses being used in gonorrhœal affections. W.

TINCTURA DIGITALIS. *U.S., Br. Tincture of Digitalis. Tincture of Foxglove.*

"Take of Digitalis, recently dried and in fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it firmly in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Digitalis Leaves, in coarse powder, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, p. 1448.)

In preparing this tincture, great attention should be paid to the selection of the leaves, according to the rules laid down under the head of Digitalis. From a neglect of these, it is apt to be weak or inefficient. The expressed juice of the leaves, preserved by means of alcohol, prepared as the British Succi, would probably be found a powerful preparation. (See *page* 1420.) The tincture of foxglove possesses all the virtues of that narcotic, and affords a convenient method of administering it, especially in mixtures. It is said by M. Menière to deposit on standing a green oily matter, and some white lance-shaped crystals soluble in an excess of acid. (*Journ. de Pharm.*, Avril, 1861, p. 289.) The dose is from ten to twenty drops, repeated two or three times a day, and increased if necessary, but with caution. W.

TINCTURA ERGOTÆ. *Br. Tincture of Ergot.*

The *British Pharmacopœia* takes *five avoirdupois ounces* of Ergot, in coarse powder, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

The dose of this tincture is from thirty minims to two fluidrachms. W.

TINCTURA FERRI ACETATIS. *Br. Tincture of Acetate of Iron.*

"Take of Solution of Persulphate of Iron *two and a half fluidounces* [Imperial measure]; Acetate of Potash *two ounces* [avoirdupois]; Rectified Spirit *a sufficiency.* Dissolve the Acetate of Potash in ten fluidounces, and add the [Solution of] Persulphate of Iron to eight fluidounces of the Spirit, then mix the two solutions in a two-pint bottle and shake them well together, repeating the agitation several times during an hour. Put the tincture, with the precipitated salt contained in it, upon a filter, and when the liquid has ceased to run through, put as much Rectified Spirit upon the filter as will make the filtered product measure one pint." *Br.*

This is an old formula of the Dublin College, omitted at the original forma-

tion of the British Pharmacopœia, but resumed in the present edition. As in the Dublin Pharmacopœia there was no Solution of Persulphate of Iron, it was necessary to direct the preparation of this salt as a part of the formula; otherwise the process did not essentially differ from the one now officinal.

The preparation is a tincture of the teracetate of sesquioxide of iron. The first step in making it is to dissolve the two salts in rectified spirit, and to mix the solutions. A double decomposition of the salts takes place, resulting in the formation of teracetate of sesquioxide of iron which dissolves in the spirit, and sulphate of potassa which precipitates, being insoluble in that menstruum. By filtration, therefore, the sulphate of potassa is removed, and the clear liquid constitutes the tincture under notice. This tincture is a transparent liquid, of a deep-red colour, and strong ferruginous taste. It is said to be an agreeable chalybeate. The dose is from twenty drops to a teaspoonful, sufficiently diluted with water. B.

TINCTURA FERRI CHLORIDI. *U. S.* TINCTURA FERRI PERCHLORIDI. *Br.* FERRI MURIATIS TINCTURA. *Ed.* *Tincture of Chloride of Iron. Tincture of Perchloride of Iron. Tincture of Muriate of Iron.*

"Take of Iron, in the form of wire and cut in pieces, *three troyounces;* Muriatic Acid *seventeen troyounces and a half;* Alcohol *three pints;* Nitric Acid, Distilled Water, each, *a sufficient quantity.* Introduce the Iron into a flask of the capacity of two pints, pour upon it eleven troyounces of the Muriatic Acid, and allow the mixture to stand until effervescence has ceased. Then heat it to the boiling point, decant the liquid from the undissolved Iron, filter it through paper, and, having rinsed the flask with a little boiling Distilled Water, add this to it through the filter. Pour the filtered liquid into a capsule of the capacity of four pints, add the remainder of the Muriatic Acid, and, having heated the mixture nearly to the boiling point, add a troyounce and a half of Nitric Acid. When effervescence has ceased, drop in Nitric Acid, constantly stirring, until it no longer produces effervescence. Lastly, when the liquid is cold, add sufficient Distilled Water to make it measure a pint, and mix it with the Alcohol." *U. S.*

"Take of Strong Solution of Perchloride of Iron *five fluidounces;* Rectified Spirit *fifteen fluidounces.* Mix, and preserve in a stoppered bottle. Sp. gr. 0·992. This Tincture has about one-third the strength of Tinctura Ferri Sesquichloridi, *Dub.*" *Br.*

As directed in the U. S. Pharmacopœia of 1850, this preparation was made with the subcarbonate of iron of the Pharmacopœia, which is a hydrated sesquioxide, containing a small but uncertain proportion of carbonate of the protoxide. This was treated with muriatic acid, which caused some effervescence in consequence of the escape of the carbonic acid of the carbonate, and the result was a solution of the sesquichloride of iron with a little protochloride. As the proportions of subcarbonate and of acid were so arranged in the formula as to leave a slight excess of the former, provided that the acid were duly saturated, there could of course be no excess of acid in the tincture, when completed by the addition of the alcohol. But, in consequence of the presence of a small proportion of protochloride, absorption of oxygen from the air took place, and this protochloride was converted into sesquichloride and sesquioxide of iron, the latter of which, not finding any free muriatic acid to dissolve it, was precipitated. Hence the officinal tincture was apt to deposit a little sesquioxide, with the effect of losing somewhat of its chalybeate strength; and this was an objection to the U. S. formula, though a slight one, as it was easily obviated, if thought advisable, by the addition of a little more of the acid. But there were other difficulties incident to the formula, which led to its frequent partial failure, not only in incompetent hands, but even with skilful pharmaceutists. In the first place, the muriatic acid could not always be obtained of the due officinal strength (sp. gr. 1·16), and this often proved the cause of a comparatively feeble preparation. In the second place, difficulty was often experienced in effecting the solution of

the subcarbonate of iron. Properly prepared, and in its recent state, this is easily dissolved in muriatic acid; but it is exceedingly liable to undergo changes, either in its molecular condition, or state of hydration, which impair its solubility, or even render it partially insoluble. The use of heat in preparing or drying it, and the simple influence of time and exposure, have this effect in a greater or less degree; and hence the operator often found great difficulty in dissolving it in the muriatic acid. The consequence was incessant complaints of the imperfection of the formula; and, though these might not be theoretically well founded, as the formula properly executed might yield the due result, yet practically they were so, and it was certainly desirable to have a formula which would be less liable to miscarriage. Accordingly, at the late revision of the U. S. Pharmacopœia, a new process was introduced, in which the objections to the old one appear to be in great measure obviated, though nothing will secure the operator against failure, who does not take care that the materials he employs are of the proper character.*

The present U. S. formula so far imitates that of the late Dublin Pharmacopœia as to prepare directly the necessary sesquichloride by the reaction between muriatic acid and metallic iron; and the proportion of acid and iron is almost the same in both; yet they differ somewhat in the manipulations; and the U. S. formula appears, in respect to the precise method of proceeding, to be copied from that of Dr. Squibb, published in the *Am. Journ. of Pharm.* (July, 1857, p. 290).† Iron wire is chosen as the form of iron to be used because it is generally the purest. This, which is in very slight excess, is first treated with a portion of the muriatic acid which forms with it the protochloride of iron, with the escape of hydrogen, producing effervescence. The action is allowed to go on spontaneously until effervescence ceases, and is then aided by heat, which causes the saturation of the acid used. The solution being filtered, the remainder of the muriatic acid is added, and afterwards the nitric acid gradually, the liquid having been heated to the boiling point before the latter addition. The nitric acid is decomposed, with the escape of nitrous fumes producing effervescence, while, through the influence of a portion of its oxygen and the additional portion of muriatic acid, the protochloride is converted into the sesquichloride; the conversion being completed when the effervescence ceases, and the previously green colour has been changed to a reddish-brown. The precise reactions by which these changes are effected have been explained elsewhere. (See *Ferri Chloridum*, page 1170.) The process is completed by adding first enough water to make the measure of a pint, and afterwards the alcohol; thus giving precision to the product. The alcohol reacts gradually with the acid, producing a small proportion of muriatic ether, which gives a peculiar flavour to the tincture, and probably modifies in some degree its influence on the system. As the additional quantity of muriatic acid necessary to sesquichloridize the protochloride of iron first formed is just one-half of the quantity of acid first used, that is 5·5 troyounces, and as the amount added is 6·5 ounces, a slight excess of acid must be contemplated in the preparation, which may be useful in preventing precipitation, and in reacting with the alcohol to produce ether.

Mr. J. C. Wharton, of Nashville, Tenn., in commenting on the U. S. formula,

* One of the prominent difficulties in preparing this, as well as all other soluble salts of peroxide of iron, is the occasional insolubility or difficult solubility in acids of the peroxide used. This has been ascribed to some peculiar molecular condition or state of hydration, opposing itself to the action of the acid; but M. Jeannel seems to have determined that the cause of the difficulty is the presence in the peroxide of a trace of sulphuric acid in one or another mode of combination; and that, if this impurity be very carefully avoided by providing that the materials from which the oxide is prepared should be rigorously exempt from all mixture of sulphate, and that the vessels used should be washed with distilled water, the resulting peroxide will be completely soluble in acids, even diluted, and especially in muriatic acid. (*Journ. de Pharm.*, Août, 1868, p. 106.)—*Note to the thirteenth edition.*

† This process of Dr. Squibb was given in a note in the eleventh edition of the U. S. Dispensatory, page 1052.

suggests that the second portion of muriatic acid added with the object of dissolving the excess of sesquioxide produced by the nitric acid beyond the saturating power of that already combined with the protoxide, instead of being introduced before the nitric acid, so as necessarily to be in some degree evaporated with the subsequent heat and effervescence, and thus become insufficient for the object designed, should not be added until the liquid has become nearly cool, and the nitric acid has ceased to act, after which enough of it should be used to dissolve the sesquioxide produced. (*Am. Journ. of Pharm.*, Nov. 1865, p. 446.)

The British formula consists simply in the mixture of a previously prepared solution of the sesquichloride (*Liquor Ferri Perchloridi*, Br.) with three times its bulk of rectified spirit or alcohol. It is intended to make a tincture which shall have the sp. gr. 0·992.

Properties. Tincture of chloride of iron is of a reddish-brown, somewhat yellowish colour, a sour and very styptic taste, and an odour resembling that of muriatic ether. The sesquichloride of iron which it holds in solution, and on which its properties mainly depend, has been described among the preparations of iron. (See *Ferri Chloridum*, page 1170.) According to the U. S. Pharmacopœia, it has the sp. gr. 0·990; and the quantity of sesquioxide of iron which a fluidounce of it will yield, when the precipitate obtained by diluting it with water, and adding ammonia in excess, is washed, dried, and ignited, is 29 grains. The tincture is decomposed by the alkalies, alkaline earths and their carbonates, astringent vegetable infusions, and the mucilage of gum arabic, which produces with it a brown semi-transparent jelly. All these substances are, therefore, incompatible with it in prescriptions.*

Medical Properties and Uses. This is one of the most active and certain preparations of iron, usually acceptable to the stomach, and much employed for the purposes to which the chalybeates generally are applied. It has been particularly commended as a tonic in scrofula, in which it was formerly often given, jointly with the solution of chloride of calcium, or chloride of barium. It is supposed to be diuretic, and to have a peculiar influence on the urinary passages. Hence it has been employed in gleet, old gonorrhœa, and leucorrhœa; and is said to be useful in dysury dependent on spasmodic stricture of the urethra, in the dose of ten drops repeated every ten minutes, till some effect is experienced. In hemorrhages from the uterus, kidneys, and bladder, it is thought to act advantageously, but should be confined to those of a passive character, or employed only after sufficient depletion. Upon the recommendation of Dr. Bell, of Edinburgh, it has recently been much employed in erysipelas, with great supposed advantage; and, upon the same principle, that of improving the condition of the blood, has been used in various other diseases, as scarlatina, diphtheria,

**Bestuchef's tincture*, which is much used in Europe, is simply a solution of sesquichloride of iron in a mixture of one measure of ether and three or four measures of alcohol. Fr. Mayer recommends that the sesquichloride should be prepared by passing chlorine through a solution of the protochloride, until a solution of the ferridcyanide of potassium no longer produces a blue precipitate, and then evaporating by a water-bath. In this mode crystals of the sesquichloride are obtained, one ounce of which is to be dissolved in twelve ounces of ether, mixed with four times its bulk of alcohol. The solution may be rendered colourless, if desired, by exposure to the direct rays of the sun. (*N. Y. Journ. of Pharm.*, i. 233.) This decolorization, however, is effected by a chemical change which somewhat alters the character of the preparation. The sesquichloride becomes protochloride by the loss of a portion of its chlorine, which, by abstracting hydrogen from the alcohol, becomes muriatic acid; and this reacts with unaltered alcohol to form muriatic ether.

Mr. A. Cushman recommends the following process for the above tincture. He first prepares the crystals of the sesquichloride by dissolving two ounces of iron filings in a mixture of eight fluidounces of muriatic acid and four of distilled water, then adding four fluidrachms of nitric acid, evaporating to a pellicle, and setting aside to crystallize. The crystals, having been washed in alcohol, and afterwards redissolved and crystallized, are to be dissolved in a mixture of two parts of alcohol and one of ether; the proportion being an ounce of the crystals to twelve fluidounces of the mixture. After solution, the liquid is to be filtered, and exposed for 48 hours to the direct rays of the sun. (*Am. Journ. of Pharm.*, xxix. 461; from *Am. Med. Gaz.*)—*Note to the eleventh edition.*

and purulent infection of the blood. Externally it is sometimes used for the destruction of venereal warts, and as a styptic in cancerous and fungous ulcers. It has recently been employed, with success, as an injection in aneurismal tumours. (See *Ranking's Abstract*, xviii. 120.) A case of traumatic hemorrhage from the lungs is reported by Dr. Geo. W. Sternberg, in which the bleeding was promptly arrested by the inhalation of the spray of tincture of chloride of iron, by means of the atomizer; half an ounce of the tincture being diluted with five ounces of water, and the end of the tube from which the spray proceeded being placed "well back in the mouth." (*Med. Record*, Feb. 1, 1868, p. 534.) The dose of the U. S. tincture is from ten to thirty minims, which may be gradually increased to one or even two fluidrachms, two or three times a day. In acute febrile diseases, as erysipelas, the dose should be repeated every two hours. It is given diluted with water. W.

TINCTURA GALLÆ. *U. S, Br. Tincture of Nutgall. Tincture of Galls.*

"Take of Nutgall, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a glass percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Galls, in coarse powder, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

The tincture of galls is powerfully astringent; but is more used as a test than as a medicine. When long kept it ceases to evince the reactions of tannic acid, in consequence of the conversion of this into gallic acid. The dose is from one to three fluidrachms. W.

TINCTURA GENTIANÆ COMPOSITA. *U.S., Br. Compound Tincture of Gentian.*

"Take of Gentian, in moderately fine powder, *two troyounces;* Bitter Orange Peel, in moderately fine powder, *a troyounce;* Cardamom, in moderately fine powder, *half a troyounce;* Diluted Alcohol *a sufficient quantity.* Mix the powders, and, having moistened the mixture with a fluidounce and a half of Diluted Alcohol, pack it in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *one and a half avoirdupois ounces* of Gentian Root, cut small and bruised, *three-quarters of an avoirdupois ounce* of Bitter Orange Peel, cut small and bruised, *a quarter of an avoirdupois ounce* of Cardamom Seeds, freed from the pericarps and bruised, and *one Imperial pint* of Proof Spirit, and proceeds with these ingredients in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This is an elegant bitter, much used in dyspepsia, and as an addition to tonic mixtures in debilitated states of the digestive organs, or of the system generally. There is, however, much danger of its abuse, especially in chronic cases. The dose is one or two fluidrachms. W.

TINCTURA GUAIACI. *U.S. Tincture of Guaiac.*

"Take of Guaiac, in moderately coarse powder, *six troyounces;* Alcohol *a sufficient quantity.* Mix the powder thoroughly with an equal bulk of dry sand, pack the mixture moderately in a conical percolator, and, having covered it with a layer of sand, gradually pour Alcohol upon it until two pints of tincture are obtained." *U. S.*

This tincture is given in chronic rheumatism and gout, in the dose of from one to three fluidrachms three or four times a day. As it is decomposed by water, it is most conveniently administered in mucilage, sweetened water, or milk, by which the separated guaiac is held in temporary suspension. The following is a form of tincture of guaiac which the late Dr. Dewees found very efficient in the

cure of suppression of the menses and dysmenorrhœa. "Take of the best Guaiac, in powder, *four ounces;* Carbonate of Soda or of Potassa *one drachm and a half;* Pimento, in powder, *an ounce;* Diluted Alcohol *a pound.* Digest for a few days." Dr. Dewees directed a drachm or two of the spirit of ammonia to be added, "*pro re nata*," to four fluidounces of the tincture. (*Treat. on Diseases of Females*, A. D. 1826, p. 81.) The dose is a teaspoonful three times a day, to be gradually increased if necessary. Within our own experience, this remedy has seemed highly useful in painful menstruation, given in the intervals of the attacks. The quantity of alkaline addition is too small to produce any sensible effect, and the pimento can act only as a spice; so that the virtues of the tincture reside in the guaiac, and the officinal tincture would probably be found equally effectual. W.

TINCTURA GUAIACI AMMONIATA. *U. S., Br.* Tinctura Guaiaci Composita. *Lond. Ammoniated Tincture of Guaiac.*

"Take of Guaiac, in moderately coarse powder, *six troyounces;* Aromatic Spirit of Ammonia *two pints.* Macerate for seven days, and filter through paper." *U. S.*

"Take of Guaiacum Resin, in powder, *four ounces* [avoirdupois]; Aromatic Spirit of Ammonia *a sufficiency.* Macerate the Guaiacum in fifteen fluidounces [Imperial measure] of the Aromatic Spirit of Ammonia for seven days in a well-closed vessel, with occasional agitation, and filter, then add sufficient Aromatic Spirit of Ammonia to make one pint [Imp. meas.]." *Br.*

This tincture is celebrated in the treatment of chronic rheumatism, and is frequently also used in amenorrhœa. It is more stimulating, and is thought to be more effectual, than the preceding. Like that, it is decomposed by water, and should be administered in some viscid or tenacious vehicle which may hold the guaiac in suspension. The dose is one or two fluidrachms. W.

TINCTURA HELLEBORI. *U. S. Tincture of Black Hellebore.*

"Take of Black Hellebore, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a cylindrical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

This tincture, formerly called *tinctura Melampodii*, possesses the properties of black hellebore, and, upon the recommendation of Dr. Mead, has been much used in suppression of the menses. It is said to be peculiarly applicable to cases in which the grade of action is too high for the use of chalybeates. At best, however, it is an uncertain remedy, and, though frequently almost inert from the bad quality of the root, should always be administered with caution, as it is sometimes violent in its action. The dose is from thirty minims to a fluidrachm, to be taken night and morning. W.

TINCTURA HUMULI. *U. S.* Tinctura Lupuli. *Br. Tincture of Hops.*

"Take of Hops, in moderately coarse powder, *five troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it very firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Hops, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

Hops are so light and bulky that, in the proportion directed, and as prepared by the U. S. process of 1850, they absorbed almost all the spirit, which, after the requisite maceration, could be separated only by strong pressure. As this absorption of the spirit obstructed its proper action on the hops, it was necessary that the mixture should be frequently stirred during the maceration. This remark is not applicable to the present U. S. process, but continues so to that of the Br. Pharmacopœia. By thoroughly drying the hops and rubbing

them between the hands, or by cutting and bruising them, they may be brought to a state of division which will in a great measure obviate the disadvantages alluded to. As the virtues of hops depend chiefly on the lupulin, and as the quantity of this substance is different in different parcels, the tincture is necessarily unequal in strength; and the tincture of lupulin itself is preferable. (See *Tinctura Lupulinæ.*) According to M. Menière, tincture of hops deposits, on standing, a yellow precipitate, and a large quantity of a white crystalline substance, which he thinks may be malate of lime.

Tincture of hops is tonic and narcotic, and has been proposed as a substitute for laudanum when the latter disagrees with the patient; but little reliance can be placed upon it. The condition of disease to which it appears to be best adapted, is the wakefulness, attended with tremors and general nervous derangement, to which habitual drunkards are liable, and which frequently precedes an attack of delirium tremens. The dose is from one to three fluidrachms. W.

TINCTURA HYOSCYAMI. *U. S., Br. Tincture of Henbane. Tincture of Hyoscyamus.*

"Take of Henbane Leaf, in fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it firmly in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Hyoscyamus Leaves, in coarse powder, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This tincture may be advantageously substituted, as an anodyne and soporific, for that of opium, when the latter disagrees with the patient, or is objectionable on account of its property of inducing constipation. When the tincture of henbane purges, as it sometimes does, it may be united with a very small proportion of laudanum. The dose is a fluidrachm. The expressed juice preserved by means of alcohol may be used for the same purposes as the tincture. W.

TINCTURA IODINII. *U. S. Tincture of Iodine.*

"Take of Iodine *a troyounce;* Alcohol *a pint.* Dissolve the Iodine in the Alcohol." *U. S.*

This tincture has very nearly the strength of the tincture of Coindet, which contained one part of iodine to twelve of alcohol by weight; while the U. S. tincture contains one part of the former to about 12·7 parts of the latter. It is best to prepare the tincture in small quantities at a time; as the iodine reacts with the alcohol, especially when exposed to solar light, giving rise to chemical changes. The iodine should be thoroughly dried before being weighed out. The tincture should be kept in well-stopped bottles, in order to prevent the evaporation of the alcohol, and the consequent crystallization of the iodine.

The tincture of iodine has a deep-brown colour. Sixteen minims, equal to about thirty-five drops, contain one grain of iodine. It is at present less used internally than it formerly was, in consequence of an impression that it is apt to irritate the stomach. Water decomposes the tincture, and, when this is swallowed, it is supposed that the iodine is precipitated upon the mucous membrane. Besides, the tincture undergoes a gradual change when kept, owing, according to Guibourt, to a reaction between the alcohol and iodine. A portion of the latter is supposed to take hydrogen from the former, producing hydriodic acid, which combines with another portion of the iodine to form ioduretted hydriodic acid; while the place of the hydrogen in the alcohol is thought to be supplied by iodine, giving rise to another ioduretted compound. The new products are soluble in water; and consequently the tincture gradually loses by time the property of being precipitated on dilution. (*Journ. de Pharm.*, 3e sér., x. 113.) Yet, from the experiments of Dr. A. Göpel, it would appear that the change is slow if the tincture is kept in the dark and at a low temperature; for in three months a specimen thus treated had lost but one per cent. of iodine. (*Pharm. Central*

Blatt, no. 13, A.D. 1850.) On account of its liability to precipitation in the stomach, the tincture of iodine is now almost exclusively employed locally. Nevertheless, it has been prescribed with supposed advantage by M. Bérenger Féraud in the treatment of diabetes; the tincture being given in three or four fluidounces of water, in the dose of five drops, taken before a meal, at first once daily, afterwards twice, and afterwards gradually increased to twenty drops a day. (*Ann. de Thérap.*, 1866, p. 243.) Locally used, if undiluted, it acts as a powerful irritant to the skin, producing inflammation, desquamation of the cuticle, &c. Nevertheless, it is much used in this state in erysipelas, chilblains, and other cases of cutaneous and subcutaneous inflammation, and with happy effects. But its application requires some caution; and, in erysipelas, we are in the habit rather of surrounding the inflamed surface with a border of the tincture, embracing a portion of both the sound and the diseased skin, so as to prevent the progress of the inflammation, than of attempting a complete cure by covering the whole surface affected. It has been found useful in rendering the variolous eruption abortive. It has also been employed externally in croup, the bites of serpents, and local rheumatism. It is most conveniently applied by means of a camel's-hair pencil. Diluted with camphorated tincture of soap, or other alcoholic liquid, it is sometimes employed as an embrocation in scrofulous tumours and other affections requiring the use of iodine. It is much used in the radical cure of hydrocele, as an injection into the sac; and a similar employment of it has been extended to other serous cavities morbidly distended with fluid, as in ovarian dropsy, ascites, and empyema; but in these latter affections it should be resorted to, if at all, with great caution. In hydrocele, M. Velpeau employed it diluted with double its volume of water. In the other cases referred to, it has been variously diluted with from three to ten times its bulk of water, or some demulcent liquid. To prevent the precipitation of the iodine, iodide of potassium is generally added in the proportion of from two scruples to a drachm to each fluidounce of the tincture. M. Luc, an officer in the French army, having been attacked with a very violent coryza, was induced to try the effect of the local application of the vapour of the tincture, and accordingly held to his nostrils a bottle of the tincture, which he kept warm by the heat of the hand. Repeating this inhalation, which lasted nearly a minute, every three minutes for about an hour, he immediately experienced relief; and the affection went on diminishing, until, in the course of three hours, it had entirely disappeared. He afterwards tried the remedy on others, and uniformly with the same success. (*Ann. de Thérap.*, 1866, p. 236.)

The dose of the tincture is from ten to twenty drops, which may be gradually increased to thirty or forty drops, three times a day. It may be given in sweetened water, and still better in wine, when this is not contraindicated. M. Debauque, an apothecary of Mons, has ascertained that tannic acid has the property of rendering iodine soluble in water, and states that an ounce of syrup of orange-peel, in four or six ounces of water, will form a clear solution with a quantity of tincture of iodine containing five or six grains of the medicine. (*Journ. de Pharm.*, 3e sér., xx. 34.) — — — W.

TINCTURA IODINII COMPOSITA. *U. S.* Tinctura Iodi. *Br. Compound Tincture of Iodine.*

"Take of Iodine *half a troyounce;* Iodide of Potassium *a troyounce;* Alcohol *a pint.* Dissolve the Iodine and Iodide of Potassium in the Alcohol." *U. S.*

"Take of Iodine *half an ounce* [avoirdupois]; Iodide of Potassium *a quarter of an ounce* [avoird.]; Rectified Spirit *one pint* [Imperial measure]. Dissolve the Iodine and the Iodide of Potassium in the Spirit." *Br.*

The U. S. tincture is rather stronger than the British, the troyounce being heavier than the avoirdupois; while the wine pint employed in the former contains about one-fifth less than the Imperial pint employed in the latter. The difference, however, is of no great practical importance. The advantage of this tincture over the simple tincture above described is, that the former may be diluted with water without decomposition; so that, when it is swallowed, iodine is not

precipitated upon the mucous coat of the stomach, and will not, therefore, be so likely to produce gastric irritation. This is a good theoretical recommendation; but we are by no means confident that the difference of the two preparations in irritating properties will be found very striking in practice. The compound tincture of iodine may be given internally for all the purposes which iodine is capable of answering. The dose is from fifteen to thirty drops, to be gradually increased if necessary.*

Off. Prep. Vapor Iodi. W.

TINCTURA JALAPÆ. *U. S., Br.* *Tincture of Jalap.*

"Take of Jalap, in fine powder, *six troyounces;* Alcohol, Water, each, *a sufficient quantity.* Mix two measures of Alcohol with one of Water. Then moisten the powder with *two fluidounces* of the mixture, pack it moderately in a cylindrical percolator, and gradually pour the mixture upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Jalap, in coarse powder, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, p. 1448.)

In the present U. S. process the alcoholic strength of the menstruum has been considerably increased, which is an improvement in view of the resinous character of the purgative principle of jalap. The tincture possesses the medical virtues of jalap, and is sometimes added to cathartic mixtures in the quantity of one or two fluidrachms, to increase their activity. W.

TINCTURA KINO. *U. S., Br.* *Tincture of Kino.*

"Take of Kino, in fine powder, *three hundred and sixty grains;* Alcohol, Water, each, *a sufficient quantity.* Mix two measures of Alcohol with one of Water. Then mix the powder thoroughly with an equal bulk of dry sand, and, having introduced the mixture into a conical glass percolator, gradually pour the menstruum upon it until half a pint of tincture is obtained." *U. S.*

"Take of Kino, in coarse powder, *two ounces* [avoirdupois]; Rectified Spirit *one pint* [Imperial measure]. Macerate for seven days in a closed vessel, with occasional agitation, filter, and add sufficient Rectified Spirit to make one pint [Imp. meas.]." *Br.*

When maceration is employed, a good plan is to suspend the kino, confined in a bag, in the menstruum; as, when allowed to stand, in the ordinary method, the powder is apt to agglutinate, and adhere to the sides and bottom of the bottle. The tincture very frequently becomes gelatinous if kept, and at length almost entirely loses its astringency. The character of the chemical reaction which takes place remains to be investigated. The air has some effect; for if this is entirely excluded the tincture keeps for a long time without undergoing the change. The apothecary should introduce it, when prepared, into very small bottles, which should be kept well corked, and only opened when wanted for use. It is in consequence of its tendency to gelatinize, that the U. S. Pharmacopœia directs it to be frequently renewed. The dose is one or two fluidrachms. It is used

* *Tinctura Iodinii Decolorata. Colourless Iodine.* Under this name a preparation is described by Dr. N. J. Aikin, of St. Louis, Mo., which is made by mixing equal measures of Compound Tincture of Iodine and Strong Water of Ammonia. The mixture in time becomes colourless, and, if not at the end of 24 hours, more ammonia may be added, even to the extent of one-fourth if necessary. When wanted weak, it may be diluted to any desired extent by water or glycerin. In consequence of the chemical changes which take place, it is no longer tincture of iodine, but a hydro-alcoholic solution of iodides of potassium and ammonium, with more or less ammonia. It is recommended for external use whenever a discutient is required, and has also been used for its revulsive effects in inflammatory diseases, as pneumonia and rheumatism. It is recommended also topically in erysipelas, furuncles, sprains, bruises, and neuralgic affections. (*Am. J. Med. Sci.*, Oct. 1865, p. 398.) It is stated that, on the addition of ammonia, some iodide of nitrogen is generally precipitated; and, as this is an explosive compound, some caution is necessary. The deposit, however, disappears upon the completion of the decolorization. (*Am. Journ. of Pharm.*, July, 1869.)—*Note to the thirteenth edition.*

chiefly as an addition to cretaceous and other astringent mixtures in diarrhœa.* W.

TINCTURA KRAMERIÆ. *U. S., Br. Tincture of Rhatany.*

"Take of Rhatany, in moderately fine powder, *six troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it in a cylindrical glass percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Rhatany Root, in coarse powder, and *one Imperial pint* of Proof Spirit, and proceeds as directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

According to F. Boudet, the tincture of rhatany sometimes gelatinizes like that of kino (*Journ. de Pharm.*, 3e sér., i. 338); and the same observation has been made by others. The same precaution, therefore, should be observed, in relation to the mode of keeping it, as recommended in reference to tincture of kino. This is a good preparation of rhatany in cases which admit of the use of small quantities of alcohol. The dose is one or two fluidrachms.† W.

TINCTURA LIMONIS. *Br. Tincture of Lemon Peel.*

"Take of Fresh Lemon Peel, sliced thin, *two and a half ounces* [avoirdupois]; Proof Spirit, *one pint* [Imperial measure]. Macerate for seven days in a closed vessel, with occasional agitation; strain, press, and filter; then add sufficient Proof Spirit to make one pint [Imp. meas.]." *Br.*

This tincture forms a grateful aromatic addition to tonic and purgative infusions, mixtures, &c. It may be used in the dose of one or two fluidrachms. W.

TINCTURA LOBELIÆ. *U. S., Br. Tincture of Lobelia.*

"Take of Lobelia, in fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it firmly in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* prepares this Tincture from *two and a half avoirdupois ounces* of Lobelia, in coarse powder, and *one Imperial pint* of Proof Spirit, in the same manner as Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This tincture possesses the emetic and narcotic properties of lobelia, and is much used in asthma, in the dose of one or two fluidrachms, repeated every two or three hours till its effects are experienced. The emetic dose is half a fluidounce. A saturated tincture is strongly recommended by Dr. A. Livezey, as a local application in erysipelas, and the external poisonous effect of Rhus Toxicodendron. (*Bost. Med. and Surg. Journ.*, lv. 262.) W.

TINCTURA LOBELIÆ ÆTHEREA. *Br. Ethereal Tincture of Lobelia.*

"Take of Lobelia, in coarse powder, *two ounces and a half* [avoirdupois]; Spirit of Ether *one pint* [Imperial measure]. Macerate for seven days in a closed vessel, with occasional agitation; then strain, press, filter, and add sufficient Spirit of Ether to make one pint [Imp. meas.]." *Br.*

* We have received the following letter, which speaks for itself, and for which we owe our thanks to the writer.

"Louisville, Ky., June 14, 1864. *Dear Sir*,—I transmit you herewith a process for preparing Tr. Kino, which will not gelatinize, and appears to retain its qualities unimpaired. Take of Kino *one ounce and a half;* Ground Logwood *half an ounce;* Diluted Alcohol *a sufficient quantity.* Moisten the Logwood with a portion of the Diluted Alcohol, and introduce it into a displacement apparatus. Dissolve the Kino by triturating with successive portions of Dil. Alcohol, and percolate the solution through the Logwood until a pint of tincture is obtained. Yours, &c., P. F. Smith."

† In the *Pharm. Journ.* for October, 1868 (page 245), is a table prepared by Mr. W. G. Smith, of Dublin, giving the distinguishing properties of the Tinctures of Catechu, Kino, and Krameria, prepared according to the directions of the Br. Pharmacopœia. (*Note to the thirteenth edition.*)

The stimulant operation of the ether in this preparation can scarcely favour the relaxing and nauseating action for which lobelia is usually employed. The dose is the same as that of the alcoholic tincture. W.

TINCTURA LUPULINÆ. *U. S. Tincture of Lupulin.*

"Take of Lupulin *four troyounces;* Alcohol *a sufficient quantity.* Pack the Lupulin in a narrow cylindrical percolator, and gradually pour Alcohol upon it until two pints of tincture are obtained." *U. S.*

This is much superior to the tincture of hops of the first U. S. Pharmacopœia, in the place of which it was introduced into the second edition. In the original preparation, a certain quantity of hops was directed, from which the lupulin was to be separated by beating, and then digested in alcohol. As hops contain a variable proportion of lupulin, the tincture thus made must be of unequal strength; an objection to which the tincture of hops, even as now prepared, is in some measure liable. Besides, the amount of lupulin, contained in any quantity of hops upon which alcohol can conveniently act, is too small in proportion to the alcohol, to afford a tincture of the due strength. The tincture of lupulin is, therefore, greatly preferable. The dose is one or two fluidrachms, to be given in sweetened water or some mucilaginous fluid. W.

TINCTURA MYRRHÆ. *U. S., Br. Tincture of Myrrh.*

"Take of Myrrh, in moderately coarse powder, *three troyounces;* Alcohol *a sufficient quantity.* Introduce the powder into a conical percolator, press it moderately, and gradually pour Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Myrrh, in coarse powder, and *one Imperial pint* of Rectified Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

Officinal alcohol is preferable, as a solvent of myrrh, to that fluid mixed with water; because it forms a perfectly clear solution, which is not attainable with the latter menstruum. The addition of water to the tincture renders it turbid. The tincture of myrrh is scarcely ever used internally. As a local application it is employed to stimulate indolent and foul ulcers, and promote the exfoliation of bones, and, diluted with water, is applied to spongy gums, aphthous sore-mouth, and ulcerations of the throat. The dose, as a stimulant expectorant and emmenagogue, is from thirty minims to a fluidrachm. W.

TINCTURA NUCIS VOMICÆ. *U. S., Br. Tincture of Nux Vomica.*

"Take of Nux Vomica, in fine powder, *eight troyounces;* Alcohol *a sufficient quantity.* Mix the powder with a pint of Alcohol, and digest for twenty-four hours, in a close vessel, with a gentle heat; then transfer the mixture to a cylindrical percolator, and gradually pour Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two avoirdupois ounces* of Nux Vomica, and *one Imperial pint* of Rectified Spirit, and, having softened by steam, quickly dried, and then powdered the Nux Vomica, proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

It is of the greatest importance, in this process, that the nux vomica should be well powdered; and, in consequence of the difficult action of solvents on this substance, probably from the presence of bassorin, a preliminary digestion is desirable. The tincture is not an eligible form for administering nux vomica; as it is equally uncertain with the medicine in substance, and has the disadvantage of excessive bitterness. The alcoholic extract, or strychnia, is preferable. The dose of the tincture is twenty minims, to be increased if necessary. It is sometimes employed externally, in cases of local paralysis. W.

TINCTURA OPII. *U. S., Br. Tincture of Opium. Laudanum.*

"Take of Opium, dried, and in moderately fine powder, *two troyounces and a half;* Water, Alcohol, each, *a pint;* Diluted Alcohol *a sufficient quantity.*

Macerate the Opium with the Water for three days, with frequent agitation; then add the Alcohol, and continue the maceration for three days longer. Introduce the mixture into a percolator, and, when the liquid has ceased to pass, pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

"Take of Opium, in coarse powder, *one ounce and a half* [avoirdupois]; Proof Spirit *one pint* [Imperial measure]. Macerate for seven days in a closed vessel, with occasional agitation, then strain, press, filter, and add sufficient Proof Spirit to make one pint [Imp. meas.]. It contains the soluble matter of 33 grains of opium, nearly, in one fluidounce." *Br.*

The proportion of opium in these formulas is so nearly the same that the resulting tinctures may be considered identical. The apparent difference between the British formula and ours will vanish, when the relative value of the avoirdupois weight and Imperial measure, which they employ, and of the troy weight and wine measure of our Pharmacopœia, is estimated. The drying and powdering of the opium is clearly a useful provision; as it ensures greater uniformity in the strength of the tincture. Crude opium contains variable proportions of water; and laudanum prepared from a moist specimen will be weaker than that from an equal weight of the dried. The pulverization ensures the previous drying of the drug, and is thus useful independently of the greater facility which it gives to the action of the menstruum. It is troublesome, however, and is often neglected. Innovation in so important a preparation, and one in which uniformity is so desirable, should be avoided, unless shown to be necessary. There can be little doubt, we think, that the present somewhat elaborate method of the U. S. formula ensures a more complete exhaustion of the opium than the former simple procedure of maceration for two weeks, and still more so than the British process, which macerates for only one week.

In the United States and Great Britain, this tincture is universally known by the name of *laudanum*. As this term was formerly applied to other preparations of opium, and still continues to be so on the continent of Europe, the tincture is sometimes distinguished by the epithet *liquidum*, which, however, is seldom used in this country. *Tinctura Thebaica* is another title by which the preparation is known.

About two-thirds of the opium used in the preparation of the tincture are dissolved, the residue consisting chiefly of inert matter. Allowing the opium to be wholly exhausted of its active principles, one grain would be represented by 12·8 minims, according to the U. S. formula; but a minute quantity of morphia has been detected in the residuary matter, so that the tincture is rather weaker than the proportion of opium employed would indicate. The difference, however, is insufficient to be of any practical importance.

The tincture of opium is used for all the purposes to which opium itself is applied. (See *Opium.*) The dose, equivalent to a grain of opium, is about thirteen minims, or twenty-five drops. Mr. Phillips, in his translation of the London Pharmacopœia of 1836, states that, by evaporating the tincture, and also by determining the quantity of opium left undissolved, he found the preparation to contain one grain of opium in 19 minims; and this quantity, therefore, is given as the dose equivalent to a grain of opium. But this mode of calculation is obviously fallacious; as the portion of the drug dissolved is much more active than that left behind by the menstruum. Indeed, so feeble is the latter, that Dr. Garrod gave thirty grains of the residue to a healthy adult without effect. (*Pharm. Journ.*, xi. 252.) It should be recollected that a fluidrachm or teaspoonful of laudanum (60 minims) will yield, on an average, about 120 drops. Laudanum when long kept, with occasional exposure to the air, becomes thick from the evaporation of a portion of the alcohol, and the deposition of opium. If given in this state, it often acts with unexpected energy; and death has resulted in infants from its use in doses which would have been entirely safe if the tincture had been clear.

Denarcotized laudanum may be prepared by substituting the extract of

opium in half the quantity for the opium itself, and, previously to the maceration in diluted alcohol, exhausting it of the narcotina by ether.*

Off. Prep. Enema Opii, *Br.*; Linimentum Opii, *Br.* W.

TINCTURA OPII ACETATA. *U. S. Acetated Tincture of Opium.*

"Take of Opium, dried, and in moderately fine powder, *two troyounces*; Vinegar *twelve fluidounces*; Alcohol *half a pint*. Rub the Opium with the Vinegar; then add the Alcohol, and, having macerated for seven days, express, and filter through paper." *U. S.*

This preparation was introduced into the second edition of our Pharmacopœia as a substitute for the *Acetum Opii* or *black drop* of the original work, the advantages of which it was supposed to possess, without being liable to the same objection of uncertainty of strength. The Acetum Opii, however, having maintained its standing in the estimation of the profession, and of the public, was restored, in the edition of 1840, to its officinal rank, but so modified as to ensure a preparation as uniform as is consistent with the variable quality of the opium used. (See *page* 950.) At the same time the formula for the acetated tincture was retained, as affording a useful preparation. It was originally employed by the late Dr. Joseph Hartshorne, of Philadelphia.

The acetated tincture of opium may often be advantageously used in cases in which laudanum or opium itself produces unpleasant effects, such as nausea and vomiting, intense headache, great nervous disorder, &c.; but the introduction of the salts of morphia into use has in a great measure superseded the necessity of

* *Elixir of Opium.* Under this name have been sold different liquid preparations of opium, consisting mainly, in all probability, of an aqueous solution, with sufficient alcohol to preserve it. A formula of this kind was published by Mr. Eugene Dupuy, of New York, in the *Am. Journ. of Pharm.* (xxiii. 211). Professor Procter in the same place gave a formula, differing from that of Mr. Dupuy in the employment of ether, so as to obtain at one operation a preparation analogous to the denarcotized laudanum mentioned in the text. This formula of Prof. Procter has been adopted, with some slight change, in the present edition of the U. S. Pharmacopœia, under the title of *Tinctura Opii Deodorata*, which will be found in the text.

Since the publication of the eleventh edition of the U. S. Dispensatory, the supposed composition of the nostrum, long noted and much used under the name of *McMunn's Elixir of Opium*, has been published in the *Medical and Surgical Reporter* of this city; the formula having been furnished to that journal as found among the papers of the late Dr. Chilton, of New York, who is supposed to have received it from the proprietor. The following is an abstract of the formula. Five pounds of opium were first exhausted by ether of everything soluble in that menstruum, including the narcotina and the odorous principle. The drug was then introduced into water heated short of the boiling point, which caused a strong ebullition through the escape of the ether remaining in the mass. After the expulsion of the ether, it was macerated to exhaustion with water sufficient to make, when strained, four gallons of infusion; and if the quantity fell short of this, enough boiling water was added to complete the measure. After standing for five or six days in a cool cellar, the clear liquor was removed, and, the residue having been filtered, was mixed with the filtrate. To the four gallons of watery infusion thus prepared five and a half gallons of alcohol were added, and the mixture set aside for a few days, when the clear part was ladled out and the dregs filtered as before. The strength was intended to be the same as that of laudanum. (See *Am. Journ. of Pharm.*, May, 1864, p. 262.)

In the same journal (March, 1860, p. 129) Dr. Squibb published the formula of what he denominates "*Liquor Opii Compositus*," of which the outline is, *first*, the exhaustion of the opium with water; *secondly*, after concentration of the infusion, the addition of alcohol so as to dissolve everything soluble in that liquid; *thirdly*, after concentration of the clear alcoholic solution, the washing of the residue with ether, the ethereal washings being rejected; *fourthly*, the solution of the washed extract in water, with subsequent filtration; *fifthly*, the assaying of the watery solution to ascertain the proportion of morphia; and *lastly*, adding to the solution so much compound spirit of ether (Hoffmann's anodyne) as to make each fluidounce of the resulting compound solution of opium contain four grains of morphia and fifty-six grains of the compound spirit of ether, representing the average morphia strength of the officinal tincture of opium. For particulars the reader is referred to the communication of Dr. Squibb, in the above-mentioned journal. Most of these extra-officinal preparations of opium will probably be superseded by the excellent officinal introduced into the present edition of our Pharmacopœia, under the name of *Tinctura Opii Deodorata*. (*Note to the twelfth edition.*)

this preparation. The dose is ten minims, or about twenty drops, equivalent to a grain of opium. W.

TINCTURA OPII AMMONIATA. *Br. Ammoniated Tincture of Opium.*

"Take of Opium, in coarse powder, *one hundred grains;* Saffron, cut small, Benzoic Acid, of each, *one hundred and eighty grains;* Oil of Anise *one fluidrachm;* Strong Solution of Ammonia *four fluidounces* [Imperial measure]; Rectified Spirit *sixteen fluidounces* [Imp. meas.]. Macerate for seven days, in a well-closed vessel, with occasional agitation, then strain, press, filter, and add sufficient Rectified Spirit to make one pint." *Br.*

This is an old preparation of the Edinburgh Pharmacopœia, formerly used in Scotland under the name of Paregoric Elixir. It differs, however, both in composition and strength, from the very popular preparation known by the same common name in the United States. As ammonia precipitates morphia from its solutions, it was doubted whether the tincture contained any of that alkaloid; and to decide the question, Mr. Gilbert, of Nottingham, England, submitted portions of the tincture to chemical examination, and was unable to detect morphia. (*Med. Examiner*, iv. 493.) But, while ammonia precipitates morphia, a great excess of it redissolves the precipitate, and, according to Dr. Christison, if prepared according to the Edinburgh formula, in which a strong alcoholic solution is employed, there is a sufficient excess of ammonia to produce this effect; while we are not informed whether the tincture examined by Dr. Gilbert was made with this spirit of ammonia, or the much weaker spirit of the London College; so that his experiments cannot be admitted as conclusive. At best, however, the preparation is of doubtful propriety; as, if the ammoniacal addition should not happen to have the requisite strength, or if the ammonia should escape or become carbonated by exposure, the strength of the tincture might be affected. Influenced, we presume, by considerations of this kind, the editors of the first British Pharmacopœia rejected the preparation altogether. But popular preference, though local, seems to have led to its readmission into the Br. Pharmacopœia at its late revision, though in a slightly modified form; strong solution of ammonia and rectified spirit being substituted for the Edinburgh spirit of ammonia, which is not officinal in the Br. Pharmacopœia. The dose is stated at from thirty minims to a fluidrachm. W.

TINCTURA OPII CAMPHORATA. *U. S.* Tinctura Camphoræ Composita. *Br. Camphorated Tincture of Opium. Compound Tincture of Camphor. Paregoric Elixir.*

"Take of Opium, dried, and in moderately fine powder, Benzoic Acid, each, *sixty grains;* Camphor *forty grains;* Oil of Anise *a fluidrachm;* Clarified Honey *two troyounces;* Diluted Alcohol *two pints.* Macerate for seven days, and filter through paper." *U. S.*

"Take of Opium, in coarse powder, Benzoic Acid, of each, *forty grains;* Camphor *thirty grains;* Oil of Anise *half a fluidrachm;* Proof Spirit *one pint* [Imperial measure]. Macerate for seven days in a closed vessel, with occasional agitation, then filter, and add sufficient Proof Spirit to make one pint [Imp. meas.]." *Br.*

This is the well-known *paregoric elixir.* It is a very pleasant anodyne and antispasmodic, much used to allay cough in chronic catarrh, asthma, consumption, pertussis, &c.; to relieve nausea and slight pains in the stomach and bowels; to check diarrhœa; and, in infantile cases, to procure sleep. Half a fluidounce of the U. S. and British tincture contains rather less than a grain of opium. Liquorice, which was directed in a former edition of the U. S. Pharmacopœia, was omitted in that of 1840, in consequence of giving to the preparation the dark colour of laudanum, and thus leading to mistake. The dose for an infant is from five to twenty drops, for an adult from one to two fluidrachms.*

Off. Prep. Mistura Glycyrrhizæ Composita, *U. S.* W.

* The following formulas have been adopted by the Philadelphia College of Pharmacy for the preparation of the two compound tinctures of opium, so much used under the

TINCTURA OPII DEODORATA. *U. S.* *Deodorized Tincture of Opium.*

"Take of Opium, dried, and in moderately fine powder, *two troyounces and a half;* Ether, Alcohol, each, *half a pint;* Water *a sufficient quantity.* Macerate the Opium with half a pint of Water for twenty-four hours, and express; then repeat the operation twice with the same quantity of Water. Mix the expressed liquids, and, having evaporated the mixture to four fluidounces, shake it when cold, in a bottle, repeatedly with the Ether. Pour off the ethereal solution when it has separated by standing, and evaporate the remaining liquid until all traces of ether have disappeared. Mix this with twenty fluidounces of Water, and filter the mixture through paper. When the liquid has ceased to pass, add sufficient Water, through the filter, to make the filtered liquid measure a pint and a half. Lastly, add the Alcohol, and mix them together." *U. S.*

This is an excellent preparation of opium, calculated to supersede various extra-officinal *elixirs* or *solutions*, which have had more or less vogue, based upon the real advantages they afforded, in offering liquid preparations of opium exempt from certain noxious ingredients in the crude drug and in the officinal tinctures, which rendered them so offensive to some constitutions, and in some conditions of disease, as almost to forbid their use. A liquid watery extract is first made, in which are left behind all the ingredients of opium soluble in alcohol and not in water; and this being well shaken with ether, is further deprived of all the principles soluble in this fluid, including narcotina, and the noxious odorous matter, which is probably one of the most offensive and least useful constituents of opium. The ether is then entirely separated, and the residue having been dissolved in water, the solution is filtered, and mixed with enough alcohol to preserve it. The name is, we think, unfortunate, as the preparation is really not a tincture; the alcohol being used in no degree as a menstruum, but only in reference to its preservative influence. We should have preferred *Infusum Opii Deodoratum*, or some other title expressive of the fact that it is effectively a watery solution of an extract of opium, deprived of the odorous and other injurious ingredients of that drug. It may be used in all cases in which laudanum is indicated, but in which it cannot be used in consequence of idiosyncrasy of the patient, or peculiarity in the disease. The dose is the same as that of the officinal tincture of opium. W.

TINCTURA PYRETHRI. *Br.* *Tincture of Pellitory.*

The *British Pharmacopœia* takes *four avoirdupois ounces* of Pellitory Root, in coarse powder, and *one Imperial pint* of Rectified Spirit, and proceeds in the manner directed for Tincture of Aconite. (See *Tinctura Aconiti*, page 1448.)

This is a new officinal of the Br. Pharmacopœia, intended exclusively for external use. It is a powerful local irritant. For its uses, the reader is referred to the article on Pellitory in *Part* I. of this work. W.

names of *Bateman's drops* and *Godfrey's cordial*. So long as these nostrums are employed, it is important that they should be prepared in a uniform manner, and of a certain strength; as serious consequences may happen from diversity in the formulas, when so active a substance as opium is the chief ingredient. Such diversity has existed to a very great extent; so much so that in one formula for Bateman's drops the quantity of opium was seven and a half grains to the pint, while in another it exceeded one hundred grains. It was in order to remedy this evil that the College was induced to adopt the formulas here presented.

"*Bateman's pectoral drops.* Take of Diluted Alcohol Cong. iv, Red Saunders, rasped, ℥ij. Digest for twenty-four hours, filter, and add of Opium, in powder, ℥ij, Catechu, in powder, ℥ij, Camphor ℥ij, Oil of Anise f℥iv. Digest for ten days." This preparation is about equal in strength to the camphorated tincture of opium or paregoric elixir of the U. S. Pharmacopœia, containing about two grains of opium to the fluidounce.

"*Godfrey's cordial.* Take of Tincture of Opium Oiss, Molasses (from the sugar refiners) Oxvj, Alcohol Oij, Water Oxxvj, Carbonate of Potassa ℥iiss, Oil of Sassafras f℥iv. Dissolve the Carbonate of Potassa in the Water, add the Molasses, and heat over a gentle fire till they simmer; take off the scum which rises, and add the Laudanum, Alcohol, and Oil of Sassafras, having previously mixed them well together." This preparation contains the strength of rather more than one grain of opium in a fluidounce. (*Journ. of the Phil. Col. of Pharm.*, v. 26 and 27.)

TINCTURA QUASSIÆ. *U. S., Br. Tincture of Quassia.*

"Take of Quassia, in moderately fine powder, *two troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

"Take of Quassia Wood, in chips, *three-quarters of an ounce* [avoirdupois]; Proof Spirit *one pint* [Imperial measure]. Macerate for seven days in a closed vessel, with occasional agitation, then strain, press, filter, and add sufficient Proof Spirit to make one pint [Imp. meas.]." *Br.*

This tincture was omitted in the first British Pharmacopœia, but has been resumed in the present. The proportion of the quassia, though somewhat greater than in the old Edinburgh formula, is still much too small. A fluidrachm, which is the medium dose, represents only about two grains of the wood.

In the edition of the U. S. Pharmacopœia of 1840, the proportion of the quassia to the menstruum was very judiciously doubled. A tonic tincture can scarcely contain too large a proportion of the active ingredient. The tincture may be employed as an addition to tonic infusions or mixtures in the dose of one or two fluidrachms. It is a pure and intense bitter. W.

TINCTURA QUINIÆ. *Br. Tincture of Quinia.*

"Take of Sulphate of Quinia *one hundred and sixty grains;* Tincture of Orange Peel *one pint* [Imperial measure]. Dissolve the Sulphate of Quinia in the Tincture with the aid of a gentle heat; then allow the solution to remain for three days in a closed vessel, shaking it occasionally; and afterwards filter." *Br.*

A fluidrachm of this preparation, containing a grain of sulphate of quinia, may be given for a dose. W.

TINCTURA RHEI. *U. S., Br. Tincture of Rhubarb.*

"Take of Rhubarb, in moderately coarse powder, *three troyounces;* Cardamom, in moderately fine powder, *half a troyounce;* Diluted Alcohol *a sufficient quantity.* Mix the powders, and, having moistened the mixture with a fluidounce of Diluted Alcohol, pack it moderately in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes of Rhubarb Root, in coarse powder, *two avoirdupois ounces;* of Cardamom Seeds, freed from their pericarps, and bruised, Coriander Fruit, bruised, and Saffron, of each, *a quarter of an avoirdupois ounce,* and *one Imperial pint* of Proof Spirit; and with these ingredients proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti,* page 1448.)

TINCTURA RHEI ET ALOËS. *U. S.* 1850, *Ed.* Elixir Sacrum. *Tincture of Rhubarb and Aloes. Sacred Elixir.*

"Take of Rhubarb, bruised, *ten drachms;* Aloes, in powder, *six drachms;* Cardamom [seeds], bruised, *half an ounce;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper." *U. S.* 1850.

The *Ed. College* took *a troyounce and a half* of Rhubarb, *six drachms* of Socotrine or E. India Aloes, both in moderately fine powder, *five drachms* of bruised Cardamom seeds, and *two Imperial pints* of Proof Spirit, moistened the solid materials with a little of the Spirit, and, having allowed the mass to stand for ten or twelve hours, packed it in a percolator, and poured on the remainder of the Spirit.

TINCTURA RHEI ET GENTIANÆ. *U. S.* 1850, *Ed. Tincture of Rhubarb and Gentian.*

"Take of Rhubarb, bruised, *two* [*troy*]*ounces;* Gentian, bruised, *half a* [*troy*] *ounce;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper." *U. S.* 1850.

The *Ed. College* took *two troyounces* of Rhubarb, in moderately fine powder,

half a troyounce of Gentian, finely cut or in coarse powder, and *two Imperial pints* of Proof Spirit, and proceeded in the same manner as above indicated for Tincture of Rhubarb and Aloes.

The foregoing tinctures of Rhubarb, of which the first only is now officinal, are all in a greater or less degree purgative, stomachic, and tonic; but, except in low states of the system, or in cases of individuals accustomed to the use of ardent spirits, they are too feebly cathartic in proportion to their stimulant power, to be advantageously employed, unless as adjuvants to other medicines. Combined with the neutral salts or other laxatives, or with tonic and stomachic infusions, mixtures, &c., they serve to render them warmer and more cordial to the stomach, and often prove beneficial in flatulent colic, dyspepsia, the costiveness of cold and irritable habits, diarrhœa, and other analogous complaints. One of them is to be preferred to another, according as its peculiar composition may, in the judgment of the practitioner, appear to adapt it to the circumstances of the case under treatment. In low forms of fever, when the indication is to evacuate the bowels, and at the same time stimulate the patient, the simple tincture (*Tinctura Rhei*) may be advantageously used in doses of two or three fluidrachms, repeated at proper intervals till it operates. The ordinary dose of these tinctures, as purgatives, is from half a fluidounce to a fluidounce; as stomachics, from one to two or three fluidrachms. According to Menière, the tincture of rhubarb yields on standing an abundant greenish precipitate, containing starch,* and consisting of two parts, one soluble and the other insoluble in alcohol, the latter having the form of long needles. (*Journ. de Pharm.*, Avril, 1861, p. 290.) From the statements of De la Rue and Muller it appears that much of the deposit in tincture of rhubarb consists of chrysophanic acid, suggesting the propriety, at least in a pharmaceutical point of view, of increasing the alcoholic strength of the menstruum. W.

TINCTURA RHEI ET SENNÆ. *U. S.* *Tincture of Rhubarb and Senna.*

"Take of Rhubarb, in moderately coarse powder, *a troyounce;* Senna, in moderately coarse powder, Red Saunders, in moderately coarse powder, each, *one hundred and twenty grains;* Coriander, in moderately coarse powder, Fennel, in moderately coarse powder, Liquorice [extract], in moderately coarse powder, each, *thirty grains;* Raisins, deprived of their seeds, *six troyounces;* Diluted Alcohol *three pints.* Macerate for fourteen days, express, and filter through paper." *U. S.*

This is the stomachic so well known, and so much used in this country, under the name of *Warner's gout cordial.* It is a feeble purgative, usually acceptable to the stomach, and well adapted to cases of costiveness, with gastric uneasiness, in persons of a gouty habit, and accustomed to the free use of alcoholic drink. The dose is from half a fluidounce to two fluidounces. W.

TINCTURA SABINÆ. *Br.* *Tincture of Savin.*

The *British Pharmacopœia* directs this Tincture to be prepared from *two and a half avoirdupois ounces* of Savin Tops, dried and coarsely powdered, and *one Imperial pint* of Proof Spirit, in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This is a new officinal of the original British Pharmacopœia. It is a convenient form for the exhibition of savin. The dose is from twenty minims to a fluidrachm. W.

* How starch should have found its way into the tincture it is difficult to understand. The observations of M. Menière were made with the microscope. He states that the deposits are made generally with extreme slowness. Whenever he noticed starch or gum, these substances were never deposited alone. In the midst of the deposits, he has often found a white pearly matter, uncrystallized, insoluble in water, which he believes to be hydrated silica, and certain salts, such as the sulphate and carbonate of lime, proceeding probably, as well as the silica, from the water used in diluting the alcohol. (*Journ. de Pharm.*, Avril, 1861, p. 288.)—*Note to the twelfth edition.*

TINCTURA SANGUINARIÆ. *U. S.* *Tincture of Bloodroot.*

"Take of Bloodroot, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

This will prove emetic in the dose of three or four fluidrachms; but it is rather intended to act as a stimulant to the stomach, expectorant, or alterative, for which purpose from thirty to sixty drops may be given. W.

TINCTURA SCILLÆ. *U. S.*, *Br.* *Tincture of Squill.*

"Take of Squill, in moderately coarse powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* directs this Tincture to be prepared from *two and a half avoirdupois ounces* of bruised Squill, and *one Imperial pint* of Proof Spirit, in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This tincture yields a grayish, rose-coloured, very bitter, and acrid deposit, consisting of silky tufts (*Menière*), possesses all the virtues of squill, and may be given for the same purposes, whenever the spirituous menstruum is not objectionable. The dose as an expectorant or diuretic is from ten to twenty minims (twenty to forty drops), and the latter quantity frequently nauseates. W.

TINCTURA SENEGÆ. *Br.* *Tincture of Senega.*

The *British Pharmacopœia* prepares this Tincture from *two and a half avoirdupois ounces* of Senega Root, in coarse powder, and *one Imperial pint* of Proof Spirit, in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

The tincture of seneka has been newly introduced into the British Pharmacopœia. It is no doubt an efficient preparation, but hardly needed while recourse can be had to the extract, syrup, and decoction. The dose is from thirty minims to two fluidrachms. W.

TINCTURA SENNÆ. *Br.* TINCTURA SENNÆ COMPOSITA. *Lond.* *Tincture of Senna.* *Compound Tincture of Senna.*

"Take of Senna, broken small, *two and a half ounces* [avoirdupois]; Raisins, freed from seeds, *two ounces* [avoird.]; Caraway Fruit, bruised, Coriander Fruit, bruised, of each, *half an ounce* [avoird.]; Proof Spirit *one pint* [Imperial measure]." With these ingredients the British Pharmacopœia prepares the tincture in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This tincture is the *elixir salutis* of the old Pharmacopœias. It is a warm cordial purgative, useful in costiveness attended with flatulence, and in atonic gout, especially when occurring in intemperate persons. It is also added to cathartic infusions and mixtures. The dose is from two fluidrachms to a fluidounce or more. Tincture of senna gives a yellow deposit, disposed in plates, containing starch and white crystals of calcareous salts. (*Menière.*)

Off. Prep. Mistura Sennæ Composita, *Br.* W.

TINCTURA SERPENTARIÆ. *U. S.*, *Br.* *Tincture of Serpentaria.* *Tincture of Virginia Snakeroot.*

"Take of Serpentaria, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Serpentary Root, in coarse powder, and *one Imperial pint* of Proof Spirit, and prepares the Tincture in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This tincture possesses the tonic and cordial properties of the root, and may be advantageously added to the infusion of Peruvian bark in low states of the system. The dose is one or two fluidrachms. W.

TINCTURA STRAMONII. *U. S., Br. Tincture of Stramonium.*

"Take of Stramonium Seed, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of bruised Stramonium Seeds, and *one Imperial pint* of Proof Spirit, and prepares the tincture as directed for the Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This tincture may be used for all the purposes for which stramonium is given, in the dose of from ten to twenty minims (twenty to forty drops), repeated twice or thrice a day, and gradually increased till it affects the system. W.

TINCTURA SUMBUL. *Br. Tincture of Sumbul.*

The *British Pharmacopœia* directs this Tincture to be prepared from *two and a half avoirdupois ounces* of Sumbul Root, in coarse powder, and *an Imperial pint* of Proof Spirit, in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This is a new officinal, very little if at all employed in this country. An account of its medical properties will be found under Sumbul, in *Part* I. of this work. The dose is from ten to thirty minims. W.

TINCTURA TOLUTANA. *U. S., Br. Tincture of Tolu.*

"Take of Balsam of Tolu *three troyounces;* Alcohol *two pints.* Macerate the Balsam with the Alcohol until it is dissolved; then filter through paper." *U. S.*

"Take of Balsam of Tolu *two ounces and a half* [avoirdupois]; Rectified Spirit *a sufficiency.* Macerate the Balsam of Tolu in fifteen fluidounces of the Spirit, in a closed vessel, with occasional agitation, for six hours, or until the Balsam is dissolved, then filter, and add sufficient Rectified Spirit to make one pint [Imperial measure]." *Br.*

The tincture of tolu has the properties of the balsam, and may be employed as an addition to expectorant mixtures in chronic catarrhal affections; but the proportion of alcohol is too large to allow of its advantageous use in ordinary cases. The dose is one or two fluidrachms. In smaller quantities it is often employed to flavour cough mixtures. It is decomposed by water.

Off. Prep. Syrupus Tolutanus, *U. S.;* Trochisci Acidi Tannici, *Br.;* Trochisci Morphiæ, *Br.;* Trochisci Morphiæ et Ipecacuanhæ, *Br.;* Trochisci Opii, *Br.* W.

TINCTURA VALERIANÆ. *U. S., Br. Tincture of Valerian.*

"Take of Valerian, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Valerian Root, in coarse powder, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

This tincture possesses the properties of Valerian, but cannot be given in ordinary cases, so as to produce the full effects of the root, without stimulating too highly, in consequence of the large proportion of spirit. The dose is from one to four fluidrachms. It deposits on standing a black, very cohesive precipitate, with starch, and a yellow extractive matter. (*Menière.*) W.

TINCTURA VALERIANÆ AMMONIATA. *U. S., Br.* TINCTURA VALERIANÆ COMPOSITA. *Lond. Ammoniated Tincture of Valerian.*

"Take of Valerian, in moderately fine powder, *four troyounces;* Aromatic

Spirit of Ammonia *two pints*. Macerate for seven days, express, and filter through paper." *U. S.*

"Take of Valerian Root, in coarse powder, *two ounces and a half* [avoirdupois]; Aromatic Spirit of Ammonia *one pint* [Imperial measure]. Macerate for seven days in a well-closed vessel, with occasional agitation, then strain, press, filter, and add sufficient Aromatic Spirit of Ammonia to make one pint [Imp. meas.]." *Br.*

The ammonia in this preparation is thought to assist the solvent powers of the alcohol, while it co-operates with the valerian in medical action. The tincture is employed as an antispasmodic in hysteria and other nervous affections. The dose is from thirty minims to a fluidrachm, and should be given in sweetened water, milk, or some mucilaginous fluid. W.

TINCTURA VERATRI VIRIDIS. *U. S., Br. Tincture of American Hellebore. Tincture of Green Hellebore.*

"Take of American Hellebore, in moderately fine powder, *sixteeen troyounces;* Alcohol *a sufficient quantity*. Moisten the powder with four fluidounces of Alcohol, pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes of Green Hellebore Root, in coarse powder, *four ounces* (avoirdupois), and of Rectified Spirit *one pint* (Imperial measure), and prepares the Tincture in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

The U. S. tincture of American hellebore is of the same strength as Dr. Norwood's tincture, which, when prepared by its author, was supposed to be saturated. This may be true of certain ingredients of the root, though probably not in reference to the active principle or principles which it may contain. The commencing dose should not exceed from three to eight drops. The British tincture is much weaker; the proportion of the root to the menstruum being, in the American tincture about as one to two, in the British as one to five. W.

TINCTURA ZINGIBERIS. *U. S., Br. Tincture of Ginger.*

"Take of Ginger, in fine powder, *eight troyounces;* Alcohol *a sufficient quantity*. Moisten the powder with two fluidounces of Alcohol, pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* prepares this Tincture from *two and a half avoirdupois ounces* of Ginger, in coarse powder, and *one Imperial pint* of Rectified Spirit, in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1448.)

The tincture of the British Pharmacopœia, though more than twice as strong as was that of the London and Edinburgh Colleges, is still too weak with ginger to be used advantageously for other purposes than to impart flavour. We greatly prefer the U. S. process, which yields a preparation in which the virtues of the ginger are not completely swallowed up in the menstruum. In consequence of the mucilaginous matter contained in ginger, the tincture made with diluted alcohol or proof spirit is apt to be turbid. Alcohol or rectified spirit is, therefore, properly preferred. Good Jamaica ginger should be used.

The tincture of ginger is a useful carminative, and may often be beneficially added to tonic and purgative infusions or mixtures, in debilitated states of the alimentary canal. The dose is from seven or eight to twenty minims. It is, however, in this country, chiefly used for the preparation of syrup of ginger, for which purpose it is necessary to employ the strong tincture of the U. S. Pharmacopœia.

Off. Prep. Syrupus Zingiberis, *U. S.* W.

TINCTURA ZINGIBERIS FORTIOR. *Br. Strong Tincture of Ginger. Essence of Ginger.*

"Take of Ginger, in fine powder, *ten ounces* [avoirdupois]; Rectified Spirit

a sufficiency. Pack the Ginger tightly in a percolator, and pour over it carefully *half a pint* [Imperial measure] of the Spirit. At the expiration of two hours add more Spirit, and let it percolate slowly until one pint [Imp. meas.] has been collected." *Br.*

This is a new officinal of the Br. Pharmacopœia, much stronger than the foregoing tincture of the same authority, and considerably more so than the American. The dose is from five to twenty minims. It is, however, chiefly used in the preparation of the Syrup.

Off. Prep. Syrupus Zingiberis, *Br.* W.

TROCHISCI.

Troches.

Troches or *lozenges* are small, dry, solid masses, usually of a flattened shape, consisting for the most part of powders incorporated with sugar and mucilage. They are designed to be held in the mouth, and dissolved slowly in the saliva, and are, therefore, adapted for the administration of those medicines only which do not require to be given in large quantities, and are destitute of any very disagreeable flavour. They are much more used, and more skilfully prepared in Europe than in this country. Tragacanth, from the greater tenacity of its mucilage, is better suited for their formation than gum arabic. The following directions for preparing them are taken from the *Dictionnaire des Drogues.* A mucilage of tragacanth is first prepared with cold water and strained. With this the powders, including sugar, are thoroughly mixed by rubbing upon a marble slab, and are thus formed into a paste, which is spread out by means of a roller upon the surface of the marble, previously powdered over with a mixture of sugar and starch. The thickness of the extended mass is rendered uniform by a frame upon which the ends of the roller rest. The upper surface is now covered with a thin layer of sugar and starch, and the mass is divided into small cakes of a particular shape by means of a punch. These cakes are placed upon paper, and, having been exposed to the air for twelve hours, are carried into a drying room moderately heated. When perfectly dry, they are thrown upon a sieve to separate the sugar and starch, and are then enclosed in bottles. In this way lozenges may be prepared from almost any medicine which the physician may deem it advisable to administer in that form. The following formula will serve as a guide. Take of citric acid, in powder, a drachm; refined sugar eight ounces; oil of lemons twelve minims; mucilage of tragacanth a sufficient quantity. Form them in the manner above directed into troches of twelve grains each. A species of lozenge is made by uniting the aromatic essential oils with sugar alone; but their preparation belongs to the confectioner rather than to the apothecary.

The troches, formerly officinal, which are omitted in the present Pharmacopœias, are those of *Tartaric Acid, Gum Arabic, Lactucarium,* and *Liquorice,* all of the late Ed. Pharmacopœia. W.

TROCHISCI ACIDI TANNICI. *Br. Tannin Lozenges. Troches of Tannic Acid.*

"Take of Tannic Acid *three hundred and sixty grains;* Tincture of Tolu *half a fluidounce;* Refined Sugar, in powder, *twenty-five ounces* [avoirdupois]; Gum Acacia, in powder, *one ounce* [avoird.]; Mucilage of Gum Acacia *two fluidounces;* Distilled Water *one fluidounce.* Dissolve the Tannic Acid in the Water, add first the Tincture of Tolu, previously mixed with the Mucilage, then the Gum and the Sugar, also previously well mixed. Form the whole into a proper mass; divide it into 720 lozenges, and dry these in a hot-air chamber with a moderate heat. Each lozenge contains half a grain of Tannic Acid." *Br.*

These are useful in relaxation of the uvula, and chronic inflammation of the fauces, being held in the mouth and allowed slowly to dissolve. W.

TROCHISCI BISMUTHI. *Br. Bismuth Lozenges. Troches of Bismuth.*

"Take of Subnitrate of Bismuth *fourteen hundred and forty grains;* Carbonate of Magnesia *four ounces* [avoirdupois]; Precipitated Carbonate of Lime *six ounces* [avoird.]; Refined Sugar *twenty-nine ounces* [avoird.]; Gum Acacia, in powder, *one ounce* [avoird.]; Mucilage of Gum Acacia *two fluidounces;* Rose Water *a sufficiency.* Mix the dry ingredients, then add the Mucilage, and form the whole into a proper mass with Rose Water. Divide the mass into 720 lozenges, and dry these in a hot-air chamber with a moderate heat. Each lozenge contains two grains of Subnitrate of Bismuth." *Br.*

These may be used to obtain the effects of subnitrate of bismuth on the system, as well as of carbonate of lime as an antacid; two or more being administered for a dose. They may also be found useful in chronic inflammation of the throat and œsophagus, by giving the mucous membrane a coating as the insoluble ingredients pass. W.

TROCHISCI CATECHU. *Br. Troches of Catechu. Catechu Lozenges.*

"Take of Pale Catechu [Gambir], in powder, *seven hundred and twenty grains;* Refined Sugar, in powder, *twenty-five ounces* [avoirdupois]; Gum Acacia, in powder, *one ounce* [avoird.]; Mucilage of Gum Acacia *two fluidounces;* Distilled Water *a sufficiency.* Mix the Catechu, Sugar, and Gum, and add the Mucilage and Water to form a proper mass. Divide into 720 lozenges, and dry these in a hot-air chamber with a moderate heat." *Br.*

These, like the troches of tannic acid, are useful in prolapsus of the uvula, and other forms of relaxation of the fauces; and may also be used, in the number of three or more at a dose, to obtain the effects of catechu on the primæ viæ and on the system. Each troche contains one grain of catechu. W.

TROCHISCI CRETÆ. *U. S. Troches of Chalk.*

"Take of Prepared Chalk *four troyounces;* Gum Arabic, in fine powder, *a troyounce;* Nutmeg, in fine powder, *sixty grains;* Sugar, in fine powder, *six troyounces.* Rub them together until they are thoroughly mixed; then with water form a mass, to be divided into Troches, each weighing ten grains." *U. S.*

These are used as a gently astringent antacid in diarrhœa. W.

TROCHISCI CUBEBÆ. *U. S. Troches of Cubeb.*

"Take of Oleoresin of Cubeb *a fluidounce;* Oil of Sassafras *a fluidrachm;* Liquorice, in fine powder, Gum Arabic, in fine powder, Sugar, in fine powder, each, *three troyounces;* Syrup of Tolu *a sufficient quantity.* Rub the powders together until they are thoroughly mixed; then add the Oleoresin and Oil, and incorporate them with the mixture. Lastly, with Syrup of Tolu form a mass, to be divided into troches, each weighing ten grains." *U. S.*

Each lozenge contains about a drop of the oleoresin of cubeb. The preparation is intended rather for effect upon the fauces and other parts of the upper alimentary passages than on the system; and may be used advantageously in some cases of chronic cough, and in ulceration or chronic inflammation of the fauces, being held in the mouth and allowed slowly to dissolve. W.

TROCHISCI FERRI REDACTI. *Br. Reduced Iron Lozenges.*

"Take of Reduced Iron *seven hundred and twenty grains;* Refined Sugar, in powder, *twenty-five ounces* [avoirdupois]; Gum Acacia, in powder, *one ounce* [avoird.]; Mucilage of Gum Acacia *two fluidounces;* Distilled Water *one fluidounce*, or *a sufficiency.* Mix the Iron, Sugar, and Gum, and add the Mucilage and Water to form a proper mass. Divide into 720 lozenges, and dry these in a hot-air chamber with a moderate heat. Each lozenge contains one grain of reduced iron." *Br.*

From one to five of the lozenges may be taken for a dose. W.

TROCHISCI FERRI SUBCARBONATIS. *U. S. Troches of Subcarbonate of Iron.*

"Take of Subcarbonate of Iron *five troyounces;* Vanilla *sixty grains;* Sugar,

in fine powder, *fifteen troyounces;* Mucilage of Tragacanth *a sufficient quantity.* Rub the Vanilla first with a part of the Sugar into a uniform powder, and afterwards with the Subcarbonate of Iron and the remainder of the Sugar until they are thoroughly mixed. Then with Mucilage of Tragacanth form a mass, to be divided into troches, each weighing twenty grains." *U. S.*

Each lozenge contains somewhat less than five grains of the subcarbonate, and from one to six may be given, according to the effects desired. (See *Ferri Subcarbonas.*) W.

TROCHISCI GLYCYRRHIZÆ ET OPII. *U. S.* TROCHISCI OPII. *Br. Troches of Liquorice and Opium. Opium Lozenges.*

"Take of Opium, in fine powder, *half a troyounce;* Liquorice, in fine powder, Gum Arabic, in fine powder, Sugar, in fine powder, each, *ten troyounces;* Oil of Anise *a fluidrachm.* Rub the powders together until they are thoroughly mixed; then add the Oil of Anise, and incorporate it with the mixture. Lastly, with water form a mass, to be divided into Troches, each weighing six grains." *U. S.*

"Take of Extract of Opium *seventy-two grains;* Tincture of Tolu *half a fluidounce;* Refined Sugar, in powder, *sixteen ounces* [avoirdupois]; Gum Acacia, in powder, *two ounces* [avoird.]; Extract of Liquorice *six ounces* [avoird.]; Distilled Water, *a sufficiency.* Add the Extract of Opium, first softened by means of a little Water, and the Tincture of Tolu, to the Extract of Liquorice heated in a water-bath. When the mixture is reduced to a proper consistence remove it to a slab, add the Sugar and Gum previously rubbed together, and mix thoroughly. Divide the mass into 720 lozenges, and dry these in a hot-air chamber with a moderate heat. Each lozenge contains one-tenth of a grain of Extract of Opium." *Br.*

A preparation equivalent to the above is much used in Philadelphia under the name of *Wistar's cough lozenges.* Sometimes sulphate of morphia is substituted in equivalent proportion for the opium, and occasionally a little tartar emetic is added; but these modifications of the officinal formula are not admissible without a change of title. The British preparation is preferable on one account, that it uses, namely, the extract of opium instead of the crude drug.

These troches are demulcent and anodyne, and useful in allaying cough, when the case admits the employment of opium, of which each of them, prepared according to the U. S. formula, contains about one-tenth of a grain. W.

TROCHISCI IPECACUANHÆ. *U. S., Br. Troches of Ipecacuanha. Ipecacuanha Lozenges.*

"Take of Ipecacuanha, in fine powder, *half a troyounce;* Arrow-root, in fine powder, *four troyounces;* Sugar, in fine powder, *fourteen troyounces;* Mucilage of Tragacanth *a sufficient quantity.* Rub the powders together until they are thoroughly mixed; then with Mucilage of Tragacanth form a mass, to be divided into Troches, each weighing ten grains." *U. S.*

"Take of Ipecacuanha, in powder, *one hundred and eighty grains;* Refined Sugar, in powder, *twenty-five ounces* [avoirdupois]; Gum Acacia, in powder, *one ounce* [avoird.]; Mucilage of Gum Acacia, *two fluidounces;* Distilled Water *one fluidounce,* or *a sufficiency.* Mix the powders and add the Mucilage and Water to form a proper mass. Divide into 720 lozenges, and dry these in a hot-air chamber with a moderate heat. Each powder contains one-fourth of a grain of ipecacuanha." *Br.*

These are useful expectorant lozenges in catarrhal complaints. Each of the U. S. lozenges contains about one-quarter of a grain of ipecacuanha. W.

TROCHISCI MAGNESIÆ. *U. S. Troches of Magnesia.*

"Take of Magnesia *four troyounces;* Nutmeg, in fine powder, *sixty grains;* Sugar, in fine powder, *twelve troyounces;* Mucilage of Tragacanth *a sufficient quantity.* Rub the Magnesia and the powders together until they are thoroughly mixed; then with Mucilage of Tragacanth form a mass, to be divided into Troches, each weighing ten grains." *U. S.*

These are useful in acidity of stomach, especially when attended with constipation. W.

TROCHISCI MENTILÆ PIPERITÆ. *U. S. Troches of Peppermint.*

"Take of Oil of Peppermint *a fluidrachm;* Sugar, in fine powder, *twelve troyounces;* Mucilage of Tragacanth *a sufficient quantity.* Rub the Oil of Peppermint with the Sugar until they are thoroughly mixed; then with Mucilage of Tragacanth form a mass, to be divided into Troches, each weighing ten grains." *U. S.*

Useful in slight gastric or intestinal pains, nausea, and flatulence; but employed more for their agreeable flavour than for their medicinal effects. W.

TROCHISCI MORPHIÆ. *Br. Morphia Lozenges. Troches of Morphia.*

"Take of Hydrochlorate of Morphia *twenty grains;* Tincture of Tolu *half a fluidounce;* Refined Sugar, in powder, *twenty-four ounces* [avoirdupois]; Gum Acacia, in powder, *one ounce* [avoird.]; Mucilage of Gum Acacia *a sufficiency;* Distilled Water *half a fluidounce.* Dissolve the Hydrochlorate of Morphia in the Water; add this solution to the Tincture of Tolu, previously mixed with *two fluidounces* of the Mucilage; then add the Gum and Sugar, previously mixed, and more Mucilage if necessary to form a proper mass. Divide into 720 lozenges, and dry these in a hot-air chamber with a moderate heat." *Br.*

Useful for alleviating cough, and for other purposes which are answered by minute doses of morphia, of the muriate of which each lozenge contains about one-thirty-sixth of a grain. W.

TROCHISCI MORPHIÆ ET IPECACUANHÆ. *Br. Morphia and Ipecacuanha Lozenges. Troches of Morphia and Ipecacuanha.*

"Take of Hydrochlorate of Morphia *twenty grains;* Ipecacuanha, in fine powder, *sixty grains;* Tincture of Tolu *half a fluidounce;* Refined Sugar, in powder, *twenty-four ounces* [avoirdupois]; Gum Acacia, in powder, *one ounce* [avoird.]; Mucilage of Gum Acacia *a sufficiency;* Distilled Water *half a fluidounce.* Dissolve the Hydrochlorate of Morphia in the Water; add this solution to the Tincture of Tolu, previously mixed with two fluidounces of the Mucilage; then add the Ipecacuanha, Gum, and Sugar, previously mixed, and more Mucilage if necessary to form a proper mass. Divide into 720 lozenges, and dry these in a hot-air chamber with a moderate heat." *Br.*

Expectorant and anodyne, useful especially in allaying cough. Each lozenge contains about one-thirty-sixth of a grain of muriate of morphia, and one-twelfth of a grain of ipecacuanha. From one to six may be given for a dose. W.

TROCHISCI POTASSÆ CHLORATIS. *Br. Chlorate of Potash Lozenges.*

"Take of Chlorate of Potash *thirty-six hundred grains;* Refined Sugar, in powder, *twenty-five ounces* [avoirdupois]; Gum Acacia, in powder, *one ounce* [avoird.]; Mucilage of Gum Acacia *two fluidounces;* Distilled Water *one fluidounce,* or *a sufficiency.* Mix the powders and add the Mucilage and Water to form a proper mass. Divide into 720 lozenges, and dry these in a hot-air chamber with a moderate heat. Each lozenge contains five grains of Chlorate of Potash." *Br.*

A new preparation of the British Pharmacopœia, useful in cases of ulcerated and diphtheric sorethroat, operating directly on the local disease, and generally, often with great benefit, through the system. From one to six of the lozenges may be taken for a dose. W.

TROCHISCI SODÆ BICARBONATIS. *U. S., Br. Troches of Bicarbonate of Soda. Bicarbonate of Soda Lozenges.*

"Take of Bicarbonate of Soda *four troyounces;* Sugar, in fine powder, *twelve troyounces;* Mucilage of Tragacanth *a sufficient quantity.* Rub the

Bicarbonate of Soda with the Sugar until they are thoroughly mixed; then with Mucilage of Tragacanth form a mass, to be divided into Troches, each weighing ten grains." *U. S.*

"Take of Bicarbonate of Soda, in powder, *thirty-six hundred grains;* Refined Sugar, in powder, *twenty-five ounces* [avoirdupois]; Gum Acacia, in powder, *one ounce* [avoird.]; Mucilage of Gum Acacia *two fluidounces;* Distilled Water *one fluidounce.* Mix the powders, and add the Mucilage and Water, to form a proper mass. Divide into 720 lozenges, and dry these in a hot-air chamber with a moderate heat. Each lozenge contains five grains of Bicarbonate of Soda." *Br.*

Antacid and antilithic, useful in heartburn and uric acid gravel. From one to six may be given for a dose. W.

TROCHISCI ZINGIBERIS. *U. S. Troches of Ginger.*

"Take of Tincture of Ginger *a fluidounce;* Tragacanth, in fine powder, *one hundred and twenty grains;* Sugar, in fine powder, *twelve troyounces;* Syrup of Ginger *a sufficient quantity.* Mix the Tincture of Ginger with the Sugar, and, having exposed the mixture to the air until dry, reduce it to fine powder; to this add the Tragacanth, and mix them thoroughly. Lastly, with Syrup of Ginger form a mass, to be divided into troches, each weighing twenty grains." *U. S.*

Each lozenge contains between one and two minims of the tincture, and they may be taken as required, being especially calculated to relieve gastric pains from flatulence. W.

UNGUENTA.

Ointments.

These are fatty substances, softer than cerates, of a consistence like that of butter, and such that they may be readily applied to the skin by inunction. When ointments are prepared by merely mixing medicinal substances with simple ointment or *lard*, care should be taken, if the added substance be a powder, that it be brought to the finest possible state of division, before being incorporated with the unctuous matter. If soluble in water or alcohol, it may often be advantageously rubbed with a little of one of these liquids. Gritty matter should not be allowed to enter these preparations. When an extract is added, if not uniformly soft, it should be made so by trituration with a little water or alcohol according to its nature. Many of the ointments become rancid if long kept, and should, therefore, be prepared in small quantities at a time, or only when wanted for use. The tendency to rancidity may be in a considerable degree counteracted by imbuing the unctuous vehicle with benzoin, or with poplar buds, as recommended by M. Deschamps (see *Am. Journ. of Pharm.*, xv. 260); but care should be taken that there be no therapeutical objection to the admixture.* Slippery elm bark is said to have the same effect. (See *page* 876.) According to Dr. Geisler, ten drops of spirit of nitric ether, incorporated with an ounce of ointment, obviates the disagreeable fatty odour of these preparations. (*Pharm. Cent. Blatt*, A. D. 1847, p. 927; from *Arch. der Pharm.*) It has been proposed to substitute glycerin for oils and fats in the preparation of ointments; but, when these are to be applied by inunction, it is altogether unfit for the purpose, as it remains upon the skin, producing a rough sensation of adhesiveness, very dif-

* *Benzinated Lard.* M. Emile Mouchon gives the following method of applying to lard the preservative influence of poplar buds and benzoin. Having prepared, by percolation, a *tincture of poplar buds* from one part of the dried buds in powder and four of alcohol, he adds by degrees to 1000 parts of melted lard 60 parts of the tincture, so that all the alcohol may be driven off, then strains, and agitates the mixture till it concretes on cooling. The same method is pursued with the tincture of benzoin, in the same proportions; and the tincture of guaiac will answer the same purpose. Lard thus prepared keeps perfectly well for a very long time. (*Journ. de Pharm.*, xxv. 458.)

Mr. T. B. Groves has shown that the oil of pimento and balsam of Peru have, in a powerful degree, the same preservative influence on lard. (*Pharm. Journ.*, Nov. 1864, p 249.)

ferent from the softness caused by oleaginous matter under similar circumstances.

The Cerates having been abolished as a class in the British Pharmacopœia, a few of the individual articles have been transferred to the Ointments, making the definition of the latter class of preparations, as given above, not exactly applicable to all the individual substances at present included among them in that Pharmacopœia. We consider no substance as strictly entitled to the name of ointment, which is not of such a consistence as to adapt it to application to the skin by friction or inunction. The ointments formerly officinal, which have been omitted in the present U. S. and Br. Pharmacopœias, are *Adeps Suillus Præparatus*, Dub., *Unguentum Conii*, Lond., *Ung. Cupri Subacetatis*, U. S., Ed., Dub., *Ung. Hydrargyri Iodidi*, Lond., *Ung. Hydrarg. Nitratis Mitius*, Lond., *Ung. Opii*, Lond., *Ung. Picis*, Lond., and *Ung. Sulphuris Compositum*, U. S., Lond. W.

UNGUENTUM ACIDI TANNICI. *U. S. Ointment of Tannic Acid.*

"Take of Tannic Acid *thirty grains;* Water *half a fluidrachm;* Lard *a troyounce*. Rub the Acid first with the Water, and then with the Lard, until they are thoroughly mixed, avoiding the use of an iron spatula." *U. S.*

Ointment of tannic acid is an excellent application in many cases of piles and prolapsus ani, and has been highly recommended in inflammation of the vagina with puruloid discharge, to which it is most conveniently applied spread thickly upon the surface of a tampon of linen. It may be used also in flabby ulcers. W

UNGUENTUM ACONITIÆ. *Br. Ointment of Aconitia.*

"Take of Aconitia, *eight grains;* Rectified Spirit *half a fluidrachm;* Prepared Lard *one ounce* [avoirdupois]. Dissolve the Aconitia in the Spirit, add the Lard, and mix thoroughly." *Br.*

For the uses of this preparation, the reader is referred to the articles on *Aconitum* and *Aconitia*. Care must be taken not to apply it to an abraded or ulcerated surface, lest it might produce serious constitutional effects. W.

UNGUENTUM ADIPIS. *U. S.* Unguentum Simplex. *Br., U. S.* 1850. *Ointment of Lard. Simple Ointment.*

"Take of Lard *eight troyounces;* White Wax *two troyounces*. Melt them together with a moderate heat, and stir the mixture constantly while cooling." *U. S.*

"Take of White Wax *two ounces* [avoirdupois]; Prepared Lard *three ounces* [avoird.]; Almond Oil *three fluidounces*. Melt the Wax and Lard in the Oil on a water-bath; then remove the mixture, and stir constantly while it cools." *Br.*

This is emollient, and is occasionally employed as a mild dressing to blistered or excoriated surfaces, but more frequently as a vehicle for more active substances. It is the basis of several officinal ointments.

Off. Prep. Ceratum Zinci Carbonatis, *U. S.;* Unguentum Antimonii Tartarati, *Br.;* Ung. Cadmii Iodidi, *Br.;* Ung. Creasoti, *Br.;* Ung. Elemi, *Br.;* Ung. Hydrargyri Ammoniati; Ung. Hydrarg. Iodidi Rubri, *Br.;* Ung. Hydrarg. Oxidi Rubri, *U. S.;* Ung. Plumbi Carbonatis; Ung. Plumbi Iodidi, *Br.;* Ung. Resinæ, *Br.* W.

UNGUENTUM ANTIMONII. *U. S.* Unguentum Antimonii Tartarati. *Br. Ointment of Antimony. Antimonial Ointment. Tartar Emetic Ointment. Ointment of Tartarated Antimony.*

"Take of Tartrate of Antimony and Potassa, in very fine powder, *one hundred and twenty grains;* Lard *a troyounce*. Rub the powder with a little of the Lard, then add the remainder, and thoroughly mix them." *U. S.*

"Take of Tartarated Antimony, in fine powder, *a quarter of an ounce;* Simple Ointment *one ounce*. Mix thoroughly." *Br.*

This may be most conveniently prepared, as in the Br. process, with *simple ointment*, as lard is too soft to be spread on linen, and simple ointment is sufficiently so to be applied by inunction.

The peculiar eruptive effects of tartar emetic may be procured by means of a strong solution, or of the powder sprinkled upon the surface or incorporated in the substance of some adhesive plaster, or of the ointment as above directed. The last method is, perhaps, the most convenient, and most generally resorted to. The proportion of tartar emetic may vary from one drachm with the ounce of lard to two drachms, as in the U. S. officinal formula, or even to three drachms when a speedy effect is required, or the skin is not very susceptible to its action. A small portion of the ointment may be rubbed twice a day, or more frequently, upon the surface to be affected, or it may be applied spread on a piece of linen. Care should be taken that the cuticle be entire, and that the application be not too long continued; as otherwise severe inflammation, and even gangrenous ulceration, may result. We have, however, in some instances of great urgency, applied the ointment to a surface recently scarified in the operation of cupping; but, under such circumstances, it should be used with much caution. W.

UNGUENTUM AQUÆ ROSÆ. *U. S. Ointment of Rose Water.*

"Take of Oil of Sweet Almonds *three troyounces and a half;* Spermaceti *a troyounce;* White Wax *one hundred and twenty grains;* Rose Water *two fluidounces.* Melt together, by means of a water-bath, the Oil, Spermaceti, and Wax; then add gradually the Rose Water, and stir the mixture constantly while cooling." *U. S.*

This preparation is much employed under the name of *cold cream.* It is a white, very soft, and elegant unguent, deriving a grateful odour from the rose water, which remains incorporated with the other constituents if kept enclosed in glazed vessels. It is a pleasant, cooling application to irritated and excoriated surfaces; and may be used with great advantage for chapped lips and hands, so frequent in cold weather. As the ointment is liable to become rancid when long kept, and the water to separate upon exposure, Mr. Joseph Laidley has proposed the substitution for the rose water of oil of roses and glycerin, the former in the proportion of two drops, the latter in that of four fluidrachms, the quantity of spermaceti being increased by two drachms. (*Am. Journ. of Pharm.*, xii. 119.) For some purposes the substitution is useful; but the officinal preparation is preferable for chapped hands, as the glycerin, not being absorbed, leaves an unpleasant sensation of stickiness on the skin. W.

UNGUENTUM ATROPIÆ. *Br. Ointment of Atropia.*

"Take of Atropia *eight grains;* Rectified Spirit *half a fluidrachm;* Prepared Lard *one ounce* [avoirdupois]. Dissolve the Atropia in the Spirit, add the Lard, and mix thoroughly." *Br.*

For the uses of this ointment, see *Belladonna* and *Atropia.* Great caution must be observed that the ointment shall not come in contact with abraded, ulcerated, or wounded surfaces; and that the cuticle of the part to which it may be applied shall be entire. W.

UNGUENTUM BELLADONNÆ. *U.S., Br. Ointment of Belladonna.*

"Take of Extract of Belladonna *sixty grains;* Water *half a fluidrachm;* Lard *a troyounce.* Rub the Extract first with the Water, until rendered uniformly soft, then with the Lard, and thoroughly mix them." *U. S.*

"Take of Extract of Belladonna *eighty grains;* Prepared Lard *one ounce* [avoirdupois]. Rub the Extract smooth with a few drops of distilled water, then add the Lard, and mix thoroughly." *Br.*

This is a convenient form for the external application of extract of belladonna. Care must be taken in preparing it that the extract employed have the due consistence; and, if dry and lumpy, it may be restored to the proper state by rubbing it with a little water in a heated mortar. W.

UNGUENTUM BENZOINI. *U. S.* ADEPS BENZOATUS. *Br. Ointment of Benzoin. Benzoated Lard.*

"Take of Benzoin, in moderately coarse powder, *a troyounce;* Lard *sixteen troyounces.* Heat them together, by means of a water-bath, for two hours, with

occasional stirring; then strain without pressure, and stir the product constantly while cooling." *U. S.*

"Take of Prepared Lard *one pound* [avoirdupois]; Benzoin, reduced to coarse powder, *one hundred and sixty grains.* Melt the Lard by the heat of a water-bath, add the Benzoin, and, frequently stirring them together, continue the application of heat for two hours; finally remove the residual Benzoin by straining." *Br.*

It has been objected to these processes that the resulting ointment is almost always of a dirty-white colour and granular in consistence, and, if heated over a direct fire, deposits the benzoin, which cannot be redissolved by heat. Mr. Thomas Doliber, of Boston, proposes to use an alcoholic solution of benzoin, instead of the balsam itself for incorporation with the lard. Having prepared a tincture by macerating six troyounces of benzoin in a pint of alcohol until dissolved, and then filtering, he rubs four fluidrachms of this tincture with sixteen ounces of lard until they are thoroughly mixed, then melts the mixture with a gentle heat, and stirs it constantly, as it cools. The ointment thus made is beautifully white and smooth, with a decided odour of benzoin, and is not liable to the objection of depositing the balsam when heated with other ointments. It has been found also to answer in practice quite as well as the officinal ointment, if not better, in the preservation of unctuous substances. The proportion of alcohol is so small as hardly to be liable to the objection of making the lard irritating. (*Am. Journ. of Pharm.*, Jan. 1867, p. 63.)

Benzoin has the property of obviating the rancidity to which lard and other unctuous substances are liable. Hence, the ointment under consideration is peculiarly useful as the vehicle of medicines used in this form; and may often be substituted for pure lard in the preparation of other unguents, of which lard is an ingredient, when it is desired to preserve them from change. It is recommended, moreover, by its agreeable odour; while there are very few ointments or cerates with the uses of which it would interfere. Balsam of Peru, rubbed with an ointment in the proportion of five drops to a fluidounce, will have the same effect.

The British Pharmacopœia uses its Benzoated Lard as an ingredient in all the suppositories and several of the ointments. W.

UNGUENTUM CADMII IODIDI. *Br. Ointment of Iodide of Cadmium.*

"Take of Iodide of Cadmium, in fine powder, *sixty-two grains;* Simple Ointment, *one ounce* [avoirdupois]. Mix thoroughly." *Br.*

A new formula of the Br. Pharmacopœia. For its uses, see Iodide of Cadmium, *page* 185. W.

UNGUENTUM CANTHARIDIS. *Br. Ointment of Cantharides. Ointment of Spanish Flies.*

"Take of Cantharides, Yellow Wax, each, *one ounce* [avoirdupois]; Olive Oil *six fluidounces.* Infuse the Cantharides in the Oil, in a covered vessel, for twelve hours, then place the vessel in boiling water for fifteen minutes, strain through muslin with strong pressure, add the product to the Wax previously melted, and stir constantly while the mixture cools." *Br.*

In former officinal processes the virtues of the flies were extracted by boiling them with water; but olive oil is a good solvent of their active principle, and has been very properly substituted in the present British formula.

By this process, the active matter of the flies is more uniformly diffused through the ointment than when they are directly incorporated, in the state of powder, with the other ingredients. The preparation is thus better calculated to meet the end proposed of maintaining the discharge from blistered surfaces, without producing undue irritation. It has been said that the virtues of the flies are impaired by boiling; but the contrary has been proved to be the case; the cantharidin being neither altered nor volatilized at 212°. (See *Cantharis.*) It should be recollected that this ointment is intended as a dressing for blisters,

not to produce vesication. We regret its omission in the present U. S. Pharmacopœia, as there is no preparation capable of answering the purpose for which it was intended so well on the whole as this. *Dupuytren's ointment*, employed as a local application to prevent the loss of hair, was made by macerating a drachm of flies in a fluidounce of alcohol, and incorporating one part of the tincture thus formed with nine parts of lard. W.

UNGUENTUM CETACEI. *Br. Spermaceti Ointment.*

"Take of Spermaceti *five ounces* [avoirdupois]; White Wax *two ounces* [avoird.]; Almond Oil *one pint* [Imperial measure], or *a sufficiency*. Melt together with a gentle heat, remove the mixture, and stir constantly while it cools." *Br.*

This ointment is employed as a mild dressing for blisters, wounds, and excoriated surfaces. It should be made in small quantities at a time, as it is apt to become rancid when long kept. W.

UNGUENTUM CREASOTI. *U. S., Br. Ointment of Creasote.*

"Take of Creasote *half a fluidrachm;* Lard *a troyounce*. Mix them." *U. S.*

"Take of Creasote *one fluidrachm;* Simple Ointment *one ounce* [avoirdupois]. Mix thoroughly." *Br.*

The British ointment is more than twice as strong as ours; but this is hardly a recommendation.

For the use of this ointment, see *Creasotum*. It may sometimes be advantageously diluted with lard when found to irritate. W.

UNGUENTUM ELEMI. *Br. Ointment of Elemi.*

"Take of Elemi *a quarter of an ounce;* Simple Ointment *one ounce*. Melt, strain through flannel, and stir constantly until the Ointment solidifies." *Br.*

This ointment is applied as a gentle stimulant to weak ulcers, and may be used for maintaining the discharge of issues and setons. It is the *linimentum arcæi* of the older pharmacy. W.

UNGUENTUM GALLÆ. *U. S., Br. Ointment of Nutgall. Ointment of Galls.*

"Take of Nutgall, in very fine powder, *a troyounce;* Lard *seven troyounces*. Mix them." *U. S.*

"Take of Galls, in fine powder, *eighty grains;* Benzoated Lard *one ounce* [avoirdupois]. Mix thoroughly." *Br.*

This is used chiefly in piles and prolapsus ani, though it may also be advantageously applied to flabby and indolent ulcers. W.

UNGUENTUM GALLÆ CUM OPIO. *Br. Ointment of Galls and Opium.*

"Take of Ointment of Galls *one ounce* [avoirdupois]; Opium, in powder, *thirty-two grains*. Mix thoroughly." *Br.*

This combination of galls and opium is sometimes employed, preferably to the simple ointment of galls, in cases of irritable piles. From half a drachm to a drachm of camphor is sometimes added to the ointment. W.

UNGUENTUM HYDRARGYRI. *U. S., Br. Mercurial Ointment.*

"Take of Mercury *twenty-four troyounces;* Lard, Suet, each, *twelve troy ounces*. Rub the Mercury with a troyounce of the Suet and a small portion of the Lard until the globules cease to be visible; then add the remainder of the Lard and of the Suet softened with a gentle heat, and thoroughly mix them." *U. S.*

"Take of Mercury, Prepared Lard, each, *one pound* [avoirdupois]; Prepared Suet *one ounce* [avoird.]. Rub them together until metallic globules cease to be visible." *Br.*

The Pharmacopœias unite at present in recognising but one mercurial ointment, which contains equal weights of mercury and fatty matter. When the

physician wishes a weaker preparation, he may direct the ointment to be diluted with such a proportion of lard as may answer his purposes.

In the preparation of mercurial ointment, care is requisite that the mercury should be completely extinguished. The trituration is best performed in a marble mortar; as it is difficult to keep iron so clean as not to impart more or less oxide to the ointment. The mercury is known to be extinguished, when a portion of the mass, rubbed upon paper or the back of the hand, exhibits no metallic globules under a magnifying glass of four powers. The operation cannot be considered as satisfactorily accomplished when the globules are invisible merely to the naked eye. To facilitate the process, which is very tedious, the addition of various substances has been proposed, calculated to hasten the disappearance of the metal. Turpentine and sulphur have been employed, but are inadmissible; the former because it renders the ointment too irritating, the latter because it forms with the mercury an inactive sulphuret Their presence in the ointment may be detected by the peculiar odour which they respectively emit when exposed to heat. Sulphur, moreover, gives the ointment a darker colour than it has when pure. The addition of a little sulphuric ether, at intervals, during the trituration, is said greatly to abbreviate the process. (*Am. Journ. of Pharm.*, xvii. 80.) Rancidity in the lard employed facilitates the extinguishment of the mercury, but is liable to the same objection as turpentine, though in a much less degree. M. Fossembras found that the addition of rancid fat was required in the proportion of only ten drachms to a pound of the ointment, in order to enable eight pounds to be prepared in an hour. (*Journ. de Pharm.*, 3e sér., v. 75.) M. Guibourt recommends the addition of one-sixteenth of old mercurial ointment.* M. Simonin proposes the use of lard which has been exposed in thin layers to a damp air for fifteen days. This facilitates the extinguishment of the metal, but it probably renders the preparation more irritant by the chemical alteration of the lard. The following plan of preparing the ointment was proposed by M. Chevallier. A pound of mercury, and half a pound of fresh lard previously melted, are introduced into a stone or glass bottle, shaken till the mixture acquires the consistency of very thick syrup, then poured into a mortar, and incorporated by constant stirring with an additional half pound of lard. In this manner, according to Chevallier, a perfect ointment may be made in half an hour. When prepared with lard alone, the ointment is apt, in hot weather, to become so soft as to allow the metal to separate. Hence the addition of suet in the processes of the U. S. and British Pharmacopœias; and even a larger proportion might be employed, when the ointment is prepared for use in the summer season.

Upon the whole, it may be considered doubtful whether any of the expedients for saving labour and time in the preparation of the ointment are wholly unobjectionable. Dr. Christison states that the better plan is not to complete the process by a continuous trituration, but to operate for a short time every day, and allow the ointment in the mean time to be exposed to the air. But so much labour is required in the process, that the ointment is preferably made by machinery on the large scale. The fatty matters, kept in the fluid state by a heat of about 100°, are triturated with the metal by means of two iron balls, which are driven rapidly round in a circular iron trough by steam power. The extinguishment of the mercury is thus effected in about twelve hours.

* It appears that Mr. J. Higginbottom made known, so long ago as the year 1814, this mode of extinguishing mercury. He recommends that equal weights of the old ointment and of mercury should be rubbed together, till the globules quite disappear, and the requisite proportion of lard then added. It is not necessary that the mercurial ointment should be rancid. (*Pharm. Journ.*, xvi. 215.) For a process recommended by Mr. J. M. Maisch, of which the peculiarity is the use of mercury passed through chamois leather, so as to be sprinkled in minute division over the fat, see the *Am. Journ. of Pharm.* (xxviii. 107); and for another by Mr. E. H. Hance, in which melted spermaceti is employed as the extinguishing material, and which is said to answer well for small quantities, see the same journal (xxix. 15). M. E. Mouchon uses wax or stearin to facilitate extinguishment, and recommends benzinated lard as the vehicle. (*Journ. de Chim. Méd.*, Nov. 1856, p. 652.)—*Note to the eleventh edition.*

A new method of preparing mercurial ointment, proposed by Orosi, is to precipitate metallic mercury, in the pulverulent form, from a solution of corrosive sublimate, by an excess of protochloride of tin, with the addition of muriatic acid; and, having poured off the supernatant fluid, washed the precipitate with warm water, and dried it between bibulous paper, to incorporate it with the prescribed proportion of lard. To prevent the precipitated mercury from running into globules, it is recommended to cover with fat the interior of the vessel in which the precipitation takes place.

Mercurial ointment has when newly prepared a bluish colour, which becomes darker by age. It has been thought to contain the mercury in the state of protoxide; but most of the metal can be separated by methods not calculated to reduce the oxide; and it is now generally admitted that by far the greater part of it exists in a state of minute division, not of chemical combination. It has been shown, however, that the metal is slightly oxidized; and the change of colour which the ointment undergoes with age is attributable to further oxidation. If the ointment be kept long melted in a narrow vessel, metallic mercury subsides, and an oily liquid floats upon the surface. After this has been filtered so as to separate everything undissolved, it is blackened by sulphuretted hydrogen, and yields oxide of mercury to acetic acid. Dr. Christison states that he has examined various samples of the ointment, and never failed to detect oxide of mercury; and he has inferred from his observations that the oxide amounts to rather more than 1 per cent. (*Christison's Dispensatory.*) But the proportion is variable, according to the age and mode of preparation of the ointment. It scarcely admits of a doubt, that the oxide of mercury formed enters into chemical combination with the lard, or one of its oily acids. Mr. Donovan advanced the idea, that the medicinal activity of the ointment depended exclusively on this compound of the lard with the mercurial oxide. An ointment made by merely mixing lard and black oxide of mercury has not the same effect; because there is no chemical union between the ingredients. But, upon exposing such a mixture to a temperature of 350°, and continually agitating it for two hours, he found that every ounce of lard dissolved and combined with twenty-one grains of oxide, and the resulting compound was proved to be equally effectual with the common ointment, and capable of being introduced into the system in one-third of the time. It has been proposed to substitute an ointment thus prepared for that made according to the officinal directions, as being more manageable, and of more uniform strength. Care, however, would be required in preparing it to avoid a temperature either too high or too low; as the former might decompose the oxide, and the latter would be insufficient to effect its union with the lard. There would be danger, also, that the lard might be rendered irritant by the influence of the heat. Dr. F. Von Baerensprung has rendered it extremely probable that metallic mercury, no matter in what state of division it may be, is unable to enter the blood-vessels, and that whatever effects on the system are produced by the ointment, or any similar preparation, or even by the vapours of mercury, are owing to the previous oxidation of the metal. (See *Chem. Gaz.*, Sept. 1, 1850, p. 321.)

From experiments by a committee of the College of Pharmacy, of New York, it appears that the ointment, contained in jars, becomes somewhat unequal in consequence of the settling of the metallic ingredient. The inference is that, after long standing, the contents of the jar should be triturated so as to restore an equable strength before being dispensed. (*Am. Journ. of Pharm.*, xvi. 2.)

Medical Uses. Mercurial ointment, when rubbed upon the surface of the body, produces, in consequence of its absorption, the general effects of mercury upon the system. It is resorted to either alone, when circumstances prevent or discourage the internal use of mercury, or conjointly with the internal use of the medicine, to produce a more speedy or powerful effect in urgent cases. It may also be advantageously employed as a resolvent in local affections; as in the case of venereal buboes, and of chronic glandular swellings, upon which it may be made to operate directly by being applied in the course of the absorbents passing

through the enlarged glands. The proper quantity to be employed at one time, with a view to salivation, is about a drachm, which should be applied night and morning, by means of friction, to the inner surface of the thighs, legs, or arms, and continued till the system is affected.

In urgent cases, or in local affections, it may also be rubbed on other parts of the body, or applied to blistered surfaces. The friction should on each occasion be continued till the whole of the ointment is absorbed. When frequently rubbed upon the same part, it is apt to produce a disagreeable eruption, which interferes with its continued application. Camphor is sometimes added, in order to render it more easy of absorption; but, without producing this effect, it increases the liability of the ointment to irritate the skin, and is of no other advantage than to soften its consistence when too firm from a large proportion of suet. Mercurial ointment has been employed, with some success, to prevent the maturation of the smallpox pustule, and the consequent pitting. For this purpose it may be applied to the face or other part, thickly spread on patent lint or muslin, care being taken to prevent the access of the air to the covered part. To be successful it must be applied before the third or fourth day of the eruption. The ointment has been recommended also in erysipelas and chilblains. Iodide of potassium, rubbed with mercurial ointment, is said to promote the separation of the mercury in the form of globules (*Journ. de Pharm*, 3e sér., x. 356); but the effect does not take place if the iodide is thoroughly dried and well powdered, and the ointment added to it by small portions at a time. (*Ibid.*, x. 421.) The ointment, diluted with twice or three times its weight of lard, is sometimes applied to ulcers, and to certain cutaneous eruptions.

Off. Prep. Linimentum Hydrargyri, *Br.;* Suppositoria Hydrargyri, *Br.;* Unguentum Hydrargyri Compositum, *Br.* W.

UNGUENTUM HYDRARGYRI AMMONIATI. *U.S.*, *Br.* Unguentum Præcipitati Albi. *Ed.* *Ointment of Ammoniated Mercury. Ointment of White Precipitate.*

"Take of Ammoniated Mercury, in very fine powder, *forty grains;* Ointment of Lard *a troyounce.* Mix them." *U. S.*

"Take of Ammoniated Mercury *sixty-two grains;* Simple Ointment *one ounce* [avoirdupois]. Mix thoroughly." *Br.*

This ointment is employed chiefly in cutaneous eruptions, such as psora, porrigo, and herpes. W.

UNGUENTUM HYDRARGYRI COMPOSITUM. *Br.* *Compound Ointment of Mercury.*

"Take of Ointment of Mercury *six ounces;* Yellow Wax, Olive Oil, of each, *three ounces;* Camphor *one ounce and a half.* Melt the Wax with a gentle heat and add the Oil, then, when the mixture is nearly cold, add the Camphor in powder, and the Ointment of Mercury, and mix the whole thoroughly together." *Br.*

The addition of camphor to mercurial ointment tends to soften it, and is thought by some to promote the absorption of the mercury. W.

UNGUENTUM HYDRARGYRI IODIDI RUBRI. *Br.* *Ointment of Red Iodide of Mercury.*

"Take of Red Iodide of Mercury, in fine powder, *sixteen grains;* Simple Ointment *one ounce* [avoirdupois]. Mix thoroughly." *Br.*

This ointment contains only one-fourth as much of the red iodide as the ointment of the Dublin College, which it supersedes. It is employed as a dressing to scrofulous ulcers, especially when they are very indolent. W.

UNGUENTUM HYDRARGYRI NITRATIS. *U.S.*, *Br.* Unguentum Citrinum. *Ed.* *Ointment of Nitrate of Mercury. Citrine Ointment.*

"Take of Mercury *a troyounce and a half;* Nitric Acid *three troyounces and a half;* Neats-foot Oil *twelve troyounces;* Lard *four troyounces and a*

half. Dissolve the Mercury in the Acid; then heat together the Oil and Lard in an earthen vessel, and, when the temperature reaches 200°, remove the mixture from the fire. To this add the mercurial solution, and with a wooden spatula stir constantly, so long as effervescence continues, and afterwards occasionally until the ointment stiffens." *U. S.*

"Take of Mercury *four ounces* [avoirdupois]; Nitric Acid *twelve fluidounces;* Prepared Lard *fifteen ounces* [avoird.]; Olive Oil *thirty-two fluidounces.* Dissolve the Mercury in the Nitric Acid with the aid of a gentle heat; melt the Lard in the Oil, by a steam or water-bath, in a porcelain vessel capable of holding six times the quantity; and, while the mixture is hot, add the Solution of Mercury, also hot, mixing them thoroughly. If the mixture do not froth up, increase the heat till this occurs. Keep it stirred until it is cold." *Br.*

The chemical changes which take place in the preparation of this ointment are not precisely known. They differ somewhat according to the circumstances under which the operation is performed; for example, according to the proportion and strength of the acid, the nature of the fatty matter, and the degree of heat employed. The mercury, in the first step of the process, is oxidized at the expense of a portion of the acid, nitrous fumes escape, and the undecomposed acid unites with the oxidized metal, forming binitrate of deutoxide of mercury if heat be employed, and a mixture of this with nitrate of the protoxide, if the process be conducted at a low temperature. When the mercurial solution is added to the fatty matter, a reaction takes place, which probably results in the production of the yellow subnitrate of the deutoxide of mercury, of one or more of the fatty acids, as the oleic, margaric, and stearic, and of elaïdin or elaïdic acid, or both. (See *page* 582.) It is also highly probable that portions of these fatty acids combine with the oxide of mercury. But the degree to which these changes take place is influenced greatly by the temperature to which the mixture is exposed. If this be low, there is little or no escape of gas; if elevated, there is a copious evolution of nitrous fumes. In the former case the changes are obviously less considerable than in the latter.

As formerly prepared, this ointment, though at first beautifully yellow and of the proper consistence, soon began to change, acquiring in time a dirty greenish and mottled colour, and becoming so hard and friable as to be unfit for use unless mixed with lard. These results were ascribed to various causes, and as many different modifications of the process were proposed in order to obviate them. The U. S. process is based upon the fact, that the olive oil of the former British processes is hardened by nitrous acid or the nitrate of mercury, while the same effect is not produced upon neats-foot oil. As at first published, the process was defective in the direction to add the mercurial solution to the mixed oleaginous fluid when it begins to stiffen on cooling. When this direction was complied with, at least with the acid of the ordinary strength, the preparation had a brown colour and semi-liquid consistence; but, with some modifications such as were introduced into the revised formula of the Pharmacopœia of 1850, the process yields an excellent ointment, which, though it sometimes assumes a greenish colour on exposure, retains permanently a soft unctuous consistence. We have had specimens of the ointment in our possession for several years, which have retained a uniform yellowish colour, and a perfectly good unctuous consistence. It is said that the lard of this formula may be advantageously replaced by the same quantity of neats-foot oil. (*Am. Journ. of Pharm.*, iv. 197.) It is probable that other animal oils will answer the same purpose; and it is asserted that a good preparation may be made with lard or butter alone. The drying vegetable oils do not appear, like olive oil, to be converted by nitrous acid or the nitrate of mercury into elaïdin; and it was a fair inference that they might be employed advantageously in the preparation of citrine ointment. Accordingly, Dr. Fessenden, of North Carolina, states, in an inaugural essay, that he substituted linseed oil for the neats-foot oil of the U. S. process, and succeeded in obtaining a perfectly good and durable ointment. It is now stated that the failure of many operators, who have followed the former British officinal pro-

cesses, has been owing not so much to the character of the particular oil employed, as to deficiency of strength in the nitric acid, and the want of a due degree of heat. Mr. Alsop asserts that, if the nitric acid be of the sp. gr. 1·5, or if the quantity of a weaker acid be increased so as to compensate for its deficiency in strength, and if the fatty matters be mixed with the mercurial solution at an elevated temperature, a permanently soft and golden-coloured ointment will result. (*Pharm. Transact.*, Sept. 1841.) In relation to the former British process, Mr. Donovan, of Dublin, states that, upon trying it, he found it to yield an ointment of a dark-mahogany colour, which did not solidify on cooling, but remained of the consistence of treacle, so that it could be poured from one vessel into another. (*Pharm. Journ.*, April, 1865, p. 541.) This result may be ascribed to a deficiency of the nitric acid in that formula, which has been corrected in the amended British process. It is probable that the discoloration which is so apt to take place in the preparation is owing to the deoxidizing influence of the fatty matter upon the mercurial oxide. Now if, by a sufficient excess of acid and an elevated temperature, the fats be well oxidized during the process, they will have less affinity for oxygen afterwards, and consequently less ability to take it from the oxide of mercury. That they are oxidized at the expense of the nitric acid, when heat is used, is proved by the abundant extrication of nitrous fumes during the operation.

But, when the fatty matter and mercurial solution are mixed, care must be taken that the heat applied be not too great. Gas is extricated at 180°, and at 212° escapes so abundantly that the mixture boils over unless the vessel is very large. (*Alsop.*) Besides, if the heat is too great, a portion of the mercury is reduced, and the colour of the ointment impaired. When large quantities of materials are operated upon, the reaction which occurs produces of itself a sufficient heat; but in ordinary cases the temperature should be kept at about 190° by means of a water-bath, and if it exceed 205° should be reduced. It should always be sufficient to produce a copious extrication of gas. The ointment should be prepared in a glass, porcelain, or well-glazed earthen vessel; and a glass rod or wooden spatula should be employed for stirring the mixture.

In the present U. S. and British formulas, the provision in relation to the application of heat is incorporated; and either of them will yield a good ointment with due care in the manipulations. For some useful practical hints upon this point, the reader is referred to a communication by Mr. Joseph Laidley in the *Am. Journ. of Pharm.* (xxii. 119). It is due to Mr. Duncan, a chemist and druggist of Edinburgh, to state that he appears to have been the first to ascertain the value of heat in the preparation of this ointment.

Medical Uses. This ointment is much and very advantageously employed, as a stimulant and alterative application, in porrigo or tinea capitis, impetigo larvalis or crusta lactea, psoriasis and pityriasis, certain forms of chronic eczema, psorophthalmia and inflammation of the eye and eyelids connected with porrigo of the face or scalp, and various other ulcerative and eruptive affections. It should be diluted with lard, unless in cases which require a very stimulant application. Some care is requisite in its use, to avoid the risk of salivation. When hard and friable, it must be rubbed up with fresh lard before it can be applied.

An ointment prepared with lard and nitric acid, called *Alyon's ointment*, after the person who first prepared it, was formerly much used in cases similar to those in which the citrine ointment is now employed. The *ointment of nitric acid* of the former Edinburgh and Dublin Pharmacopœias, discarded in the last edition of those works, was of this character. W.

UNGUENTUM HYDRARGYRI OXIDI RUBRI. *U.S.*, *Br. Ointment of Red Oxide of Mercury.*

"Take of Red Oxide of Mercury, in very fine powder, *sixty grains;* Ointment of Lard *a troyounce.* Add the Oxide of Mercury to the Ointment previously softened with a gentle heat, and thoroughly mix them." *U. S.*

"Take of Red Oxide of Mercury, in very fine powder, *sixty-two grains;*

Yellow Wax *one-quarter of an ounce* [avoirdupois]; Oil of Almonds *three-quarters of an ounce* [avoird.]. Melt the Wax at a gentle heat, mix the Oil with it, and when the mixture is nearly cold, add the Oxide of Mercury, and mix the whole thoroughly together." *Br.*

The red oxide of mercury here referred to is that prepared from the nitrate, and usually called *red precipitate.* It is important that the oxide should be thoroughly pulverized before being mixed with the lard; as otherwise it might prove injurious in cases of ophthalmia, in which it is sometimes used.

This ointment loses its fine red colour when long kept, probably in consequence of the conversion of the red oxide into the black, or its reduction to the metallic state. It is best to prepare it only in small quantities at a time. We have been informed that, if the preparation be made by mixing the red oxide with poplar-bud ointment, it will keep a long time without change. According to R. H. Stabler, of Alexandria, Va., an equally effectual method is to mix two drops of Liquor Potassæ with each ounce of the ointment when prepared. (*Am. Journ. of Pharm.*, xxiii. 123.) It is a highly useful stimulating ointment, much employed in indolent and foul ulcers, in porrigo of the scalp, psorophthalmia and chronic conjunctival ophthalmia, especially when attended with thickening of the inner membrane of the eyelids, or with specks upon the cornea. It may be diluted with lard if found too stimulating. W.

UNGUENTUM HYDRARGYRI SUBCHLORIDI. *Br.* Unguentum Calomelanos. *Br.* 1864. *Ointment of Subchloride of Mercury. Ointment of Calomel.*

"Take of Subchloride of Mercury *eighty grains;* Prepared Lard *one ounce* [avoirdupois]. Mix thoroughly." *Br.*

There is little occasion for such a preparation as this. Calomel is much inferior for affecting the system by inunction to the mercurial ointment; and as an application to ulcerated surfaces the form of cerate would be better. It may, however, be useful in certain cutaneous eruptions by being rubbed upon the part. W.

UNGUENTUM IODINII. *U.S. Ointment of Iodine.*

"Take of Iodine *twenty grains;* Iodide of Potassium *four grains;* Water *six minims;* Lard *a troyounce.* Rub the Iodine and Iodide of Potassium first with the Water, and then with the Lard until they are thoroughly mixed." *U. S.*

The object of the iodide of potassium and water is simply to bring the iodine into a state in which it may be thoroughly and equably incorporated with the lard. They have been found to answer better in practice than the alcohol formerly used.

This ointment, when rubbed upon the skin, imparts to it an orange colour, which, however, slowly disappears with the evaporation of the iodine. It is useful as a local application in goitre, scrofulous swellings of the glands and other chronic tumefactions, internal or external, operating probably through the medium of absorption. When continued for some time it occasionally produces a pustular eruption upon the portion of skin to which it is applied. Dr. Cerchiari strongly recommends it in cases of enlarged tonsils, after the disappearance of inflammation. It should be applied to the tonsils morning and evening by means of a camel's-hair pencil. In two months, according to the author, the enlargement disappears. (*Am. Journ. of Pharm.*, viii. 83.) It has also been recommended in chilblains. The ointment should be prepared only when wanted for use; for it undergoes change if kept, losing its deep orange-brown colour, and becoming pale upon the surface. W.

UNGUENTUM IODINII COMPOSITUM. *U.S.* Unguentum Iodi. *Br. Compound Ointment of Iodine.*

"Take of Iodine *fifteen grains;* Iodide of Potassium *thirty grains;* Water *thirty minims;* Lard *a troyounce.* Rub the Iodine and Iodide of Potassium first with the Water, and then with the Lard until they are thoroughly mixed." *U. S.*

"Take of Iodine, Iodide of Potassium, of each, *thirty-two grains;* Proof

Spirit *one fluidrachm;* Prepared Lard *two ounces* [avoirdupois]. Rub the Iodine and the Iodide of Potassium well together, with the Spirit, in a glass or porcelain mortar, add the Lard gradually, and mix thoroughly." *Br.*

This preparation is employed for the same purposes as the preceding, from which it differs chiefly in being somewhat stronger with iodine; as the iodide of potassium is probably not peculiar in its effects, and the spirit is employed only to facilitate the admixture. W.

UNGUENTUM MEZEREI. *U. S.* 1850. *Ointment of Mezereon.*

"Take of Mezereon, sliced transversely, *four* [*troy*]*ounces;* Lard *fourteen* [*troy*]*ounces;* White Wax *two* [*troy*]*ounces.* Moisten the Mezereon with a little Alcohol, and beat it in an iron mortar until reduced to a fibrous mass; then digest it, by means of a salt-water bath, with the Lard and Wax previously melted together, for twelve hours; strain with strong expression, and allow the strained liquid to cool slowly, so that any undissolved matters may subside. From these separate the medicated ointment." *U. S.*

Though discarded from the Pharmacopœia at the recent revision of that work, we retain the formula, because the ointment is, in our estimation, valuable for the purposes for which it was intended. It is equivalent to the *pommade épispastique au garou* of the French Codex, which is prepared from the bark of *Daphne Gnidium.* The ointment may also be made, as proposed by Guibourt, by mixing two drachms of the alcoholic extract of mezereon with nine ounces of lard and one of wax. It is used as a stimulating application to blistered surfaces in order to maintain the discharge, and to obstinate, ill-conditioned, and indolent ulcers. W.

UNGUENTUM PICIS LIQUIDÆ. *U. S., Br. Tar Ointment.*

"Take of Tar, Suet, each, *twelve troyounces.* Mix the Tar with the Suet previously melted with a moderate heat, and, having strained the mixture through muslin, stir it constantly while cooling." *U. S.*

"Take of Tar *five ounces;* Yellow Wax *two ounces.* Melt the Wax with a gentle heat, add the Tar, and stir the mixture briskly while it cools." *Br.*

This ointment is highly useful as a stimulant application in various scaly and scabby eruptions, particularly in psoriasis and lepra, and in that form of porrigo usually called tinea capitis, or scald-head. In the last-mentioned affection, it should be applied night and morning; and in bad cases the patient should constantly wear a cap, thickly coated internally with the ointment. As it is often applied to the surface with friction, the suet of the U. S. process is, we think, better suited to give a proper consistence than the wax of the British. W.

UNGUENTUM PLUMBI ACETATIS. *Br. Ointment of Acetate of Lead.*

"Take of Acetate of Lead, in fine powder, *twelve grains;* Benzoated Lard *one ounce* [avoirdupois]. Mix thoroughly." *Br.*

A new officinal of the Br. Pharmacopœia, used as a dressing for inflamed and excoriated surfaces, though inferior, we think, to the cerate of the subacetate. W.

UNGUENTUM PLUMBI CARBONATIS. *U. S., Br. Ointment of Carbonate of Lead.*

"Take of Carbonate of Lead, in very fine powder, *eighty grains;* Ointment of Lard *a troyounce.* Add the Carbonate of Lead to the Ointment previously softened with a gentle heat, and thoroughly mix them." *U. S.*

"Take of Carbonate of Lead, in fine powder, *sixty-two grains;* Simple Ointment *one ounce* [avoirdupois]. Mix thoroughly." *Br.*

This ointment is used as a dressing to blistered or excoriated surfaces, burns, &c. W.

UNGUENTUM PLUMBI IODIDI. *Br. Ointment of Iodide of Lead.*

"Take of Iodide of Lead, in fine powder, *sixty-two grains;* Simple Ointment *one ounce* [avoirdupois]. Mix thoroughly." *Br.*

Newly introduced into the Br. Pharmacopœia. For its uses, see *Plumbi Iodidum*, page 1334. W.

UNGUENTUM PLUMBI SUBACETATIS COMPOSITUM. *Br. Compound Ointment of Subacetate of Lead.*

See CERATUM PLUMBI SUBACETATIS.

UNGUENTUM POTASSÆ SULPHURATÆ. *Br. Ointment of Sulphurated Potash.*

"Take of Sulphurated Potash *thirty grains;* Prepared Lard *one ounce* [avoirdupois]. Triturate the Sulphurated Potash in a porcelain mortar and gradually add the Lard, rubbing them together until the ointment is perfectly smooth and free from grittiness. The ointment when used should be recently prepared." *Br.*

This is another officinal novelty of the Br. Pharmacopœia, which, considering its extreme simplicity of preparation, and the expediency of making it only when wanted, might well have been left to extemporaneous prescription. It may be used as a local remedy in scabies, the advanced stages of favous and eczematous affections, and all other cutaneous diseases which may have their origin in microscopic organisms. Its offensive odour may be corrected by incorporation with a little oil of anise. (See *Oleum Anisi.*) W.

UNGUENTUM POTASSII IODIDI. *U.S., Br. Ointment of Iodide of Potassium.*

"Take of Iodide of Potassium, in fine powder, *sixty grains;* Water *a fluidrachm;* Lard *a troyounce.* Dissolve the Iodide of Potassium in the Water, and mix the solution with the Lard." *U. S.*

"Take of Iodide of Potassium *sixty-four grains;* Carbonate of Potash *four grains;* Distilled Water *one fluidrachm;* Prepared Lard *one ounce* [avoirdupois]. Dissolve the Iodide of Potassium and Carbonate of Potash in the Water, and mix thoroughly with the Lard." *Br.*

The U. S. preparation is apt to become discoloured by time in consequence of the liberation of iodine. It is said that this may be prevented by mixing two drops of *Liquor Potassæ* with each ounce of the freshly prepared ointment. (*Am. Journ. of Pharm.*, xxiii. 123.) The addition of carbonate of potash by the present Br. Pharmacopœia is no doubt made with this object.

This ointment is employed for the discussion of goitres, scrofulous tumours, and other indolent swellings; and is sometimes preferred to the ointment of iodine, as it does not, like that, discolour the skin.* W.

UNGUENTUM RESINÆ. *Br. Ointment of Resin.*

See CERATUM RESINÆ.

UNGUENTUM SABINÆ. *Br. Ointment of Savin.*

See CERATUM SABINÆ.

UNGUENTUM STRAMONII. *U.S. Ointment of Stramonium.*

"Take of Extract of Stramonium *sixty grains;* Water *half a fluidrachm;* Lard *a troyounce.* Rub the Extract first with the Water until rendered uniformly soft, then with the Lard, and thoroughly mix them." *U. S.*

This is a more certain preparation than that of the former editions of the

* *Elder Ointment.* UNGUENTUM SAMBUCI, *Lond.* Though omitted in the British Pharmacopœia, we retain this preparation in its present position from its long popularity. The following was the London formula. "Take of Elder [flowers], Lard, each, *two pounds.* Boil the Elder in the Lard till it becomes crisp; then express through linen." Elder flowers impart odour to lard without adding to its virtues. An ointment, prepared in like manner from the leaves, has a green colour, and is popularly employed as a cooling application in England. Mr Joseph Ince says of the ointment prepared according to the officinal directions, that it is apt to be somewhat brownish, and to become hard and rancid; but if, after the straining through linen, it be set aside for a few days, and, after deposition and concretion, be filtered through a funnel kept hot with steam, these disadvantages will be obviated. (*Pharm. Journ.*, xiv. 489.)

U. S. Pharmacopœia, which was made by boiling the fresh leaves in lard. For remarks by Mr. A. P. Sharp, of Baltimore, on the preparation of this ointment, see the *American Journal of Pharmacy* (xxvii. 391).

The ointment of Stramonium is a useful anodyne application in irritable ulcers, painful hemorrhoids, and certain cutaneous eruptions. W.

UNGUENTUM SULPHURIS. *U. S.*, *Br.* *Ointment of Sulphur.*

"Take of Sublimed Sulphur *a troyounce;* Lard *two troyounces.* Mix them." *U. S.*

"Take of Sublimed Sulphur *one ounce;* Benzoated Lard *four ounces.* Mix thoroughly." *Br.*

The U. S. ointment is twice as strong as the British. Sulphur ointment is a specific for the itch. It should be applied every night till the complaint is cured; and it is recommended that only one-fourth of the body should be covered at a time. We have usually directed it to be applied over the whole surface, and have found no inconvenience to result. Four applications are generally sufficient to effect a cure. It is thought by some that powdered roll sulphur is more efficacious than the sublimed. Sulphur ointment, applied freely over the variolous eruption, in its early stage, is said to prevent the maturation of the pustules and consequent pitting. The disagreeable odour of the ointment may be in some measure concealed by a little oil of lemons, or oil of bergamot. W.

UNGUENTUM SULPHURIS IODIDI. *U. S.*, *Br.* *Ointment of Iodide of Sulphur.*

"Take of Iodide of Sulphur *thirty grains;* Lard *a troyounce.* Rub the Iodide of Sulphur, first reduced to a fine powder, with a little of the Lard, then add the remainder, and thoroughly mix them." *U. S.*

"Take of Iodide of Sulphur *thirty grains;* Prepared Lard *one ounce* [avoirdupois]. Triturate the Iodide of Sulphur in a porcelain mortar, and gradually add the Lard, rubbing them together until the ointment is perfectly smooth and free from grittiness." *Br.*

This is admirably adapted, as a local remedy, to the treatment of chronic cutaneous eruptions, unattended with inflammation; and is especially useful in psoriasis, lepra, porrigo, and the very advanced stages of eczema and impetigo, when they have become dry. W.

UNGUENTUM TABACI. *U. S.* *Ointment of Tobacco.*

"Take of Tobacco, in fine powder, *half a troyounce;* Lard *eight troyounces;* Water *a sufficient quantity.* Moisten the Tobacco with a little Water, introduce it into a conical glass percolator, and, having pressed it firmly, pour Water upon it until four fluidounces of filtered liquid have passed. Evaporate this to the consistence of a soft extract, and mix it thoroughly with the Lard." *U. S.*

In the first edition of the U. S. Pharmacopœia, this ointment, under the name of "Tobacco Liniment," was directed to be prepared by boiling together lard and common dried tobacco; but in this condition the leaves do not yield their virtues to lard. The error was corrected in the second edition, in which fresh tobacco was directed. Though the tobacco plant is not an object of general culture in the Northern States, it may readily be produced in gardens, in quantities sufficient to supply any demand for the fresh leaves.

Fresh narcotic vegetables yield their active principles, and chlorophyll or green colouring matter, to oleaginous substances, when heated with them; and ointments have long been prepared in this manner. In the pharmacy of the continent of Europe, olive oil is frequently employed as the solvent, and the resulting preparations are called *olea infusa.* Several of these are ordered by the French Codex, as the oils of henbane, stramonium, tobacco, &c. Lard is preferred in British and American pharmacy, as affording preparations of a more convenient consistence. The boiling takes place at a lower temperature than that necessary for the evaporation of the lard or oil, and is owing to the escape of the watery parts of the plants. It should be continued till all the water is driven off·

as this, if allowed to remain, would render the ointment more liable to spontaneous decomposition; and, besides, the colouring matter of the narcotic is not freely extracted till after the dissipation of the water. In the latest revision, however, of the Pharmacopœia, it was thought expedient to discard this method of preparing the ointment altogether, and to substitute a concentrated infusion of the dried leaves mixed with lard. The new preparation is probably quite as efficient as the old, if not more so, while pharmaceutically it is much neater.

Tobacco ointment is useful in irritable ulcers, and various cutaneous eruptions, particularly *tinea capitis;* but great care must be taken, especially in children, not to employ it in such quantities as to endanger the production of the constitutional effects of the narcotic. W.

UNGUENTUM TEREBINTHINÆ. *Br. Ointment of Turpentine.*

"Take of Oil of Turpentine *one fluidounce;* Resin, in coarse powder, *sixty grains;* Yellow Wax, Prepared Lard, of each, *half an ounce* [avoirdupois]. Melt the ingredients together by the heat of a steam or water-bath. Remove the vessel, and stir the mixture constantly while it cools." *Br.*

This is a somewhat stronger preparation than the British *Linimentum Terebinthinæ*, but is probably intended for the same purpose; as a dressing, namely, for burns, for which it is sometimes more convenient by its firmer consistence W.

UNGUENTUM VERATRIÆ. *U.S., Br. Ointment of Veratria.*

"Take of Veratria *twenty grains;* Lard *a troyounce.* Rub the Veratria with a little of the Lard; then add the remainder, and thoroughly mix them." *U. S.*

"Take of Veratria *eight grains;* Prepared Lard *one ounce* [avoirdupois]; Olive Oil *half a fluidrachm.* Rub the Veratria and the Oil together; then mix them thoroughly with the Lard." *Br.*

This ointment has been substituted for the Ointment of White Hellebore of the former edition of the U. S. Pharmacopœia, which was made by rubbing together two ounces of the powdered root, twenty minims of the Oil of Lemons, and eight ounces of Lard, and which has sometimes been employed with advantage in the itch. It is less disagreeable, but also less certain than the sulphur ointment. For the uses of veratria ointment, see the article on *Veratria.* It should be noticed that the U. S. ointment is more than twice as strong as the British. It should be employed with caution in children. W.

UNGUENTUM ZINCI OXIDI. *U.S.* UNGUENTUM ZINCI. *Br. Ointment of Oxide of Zinc. Ointment of Zinc.*

"Take of Oxide of Zinc *eighty grains;* Lard *a troyounce.* Mix them." *U. S.*

"Take of Oxide of Zinc *eighty grains;* Benzoated Lard *one ounce* [avoirdupois]. Add the Oxide of Zinc to the Benzoated Lard, previously melted with a gentle heat, and stir the mixture constantly while it cools." *Br.*

This is employed as a mild astringent application in chronic ophthalmia with a relaxed state of the vessels, in cutaneous eruptions, and in sore nipples and other instances of excoriation or ulceration. It has taken the place of the discarded *unguentum tutiæ*, or *tutty ointment*, prepared from tutty or the impure oxide of zinc, by mixing it with five parts of simple ointment. W.

VAPORES.

Vapours. Inhalations.

This is a wholly new class of preparations introduced by the British Pharmacopœia, the expediency of which, in a pharmaceutical code, is, to say the least, doubtful. There is no such complexity in the preparations as to require peculiar skill, and the whole process, in each case, is more appropriate to the duties of a nurse in the sick chamber, than to those of the pharmaceutist in the shop.

VAPOR ACIDI HYDROCYANICI. *Br. Inhalation of Hydrocyanic Acid*

"Take of Diluted Hydrocyanic Acid *ten to fifteen minims;* Water (cold)

one fluidrachm. Mix in a suitable apparatus and let the vapour that arises be inhaled." *Br.*

VAPOR CHLORI. *Br. Inhalation of Chlorine.*

"Take of Chlorinated Lime *two ounces;* Water (cold) *a sufficiency.* Put the powder into a suitable apparatus, moisten it with the Water, and let the vapour that arises be inhaled." *Br.*

VAPOR CONIÆ. *Br. Inhalation of Conia.*

"Take of Extract of Hemlock *sixty grains;* Solution of Potash *one fluidrachm;* Distilled Water *ten fluidrachms.* Mix. Put 20 minims of the mixture on a sponge, in a suitable apparatus, so that the vapour of hot water passing over it may be inhaled." *Br.*

The object of the potassa is to decompose the salt of conia in the extract, taking the acid, and liberating the alkaloid, which, being volatile, escapes with the vapour of water. The genuineness of the vapour may be known by the strong mouse-like odour which is perceived. W.

VAPOR CREASOTI. *Br. Inhalation of Creasote.*

"Take of Creasote *twelve minims;* Boiling Water *eight fluidounces.* Mix the Creasote and Water in an apparatus so arranged that air may be made to pass through the solution, and may afterwards be inhaled." *Br.*

VAPOR IODI. *Br. Inhalation of Iodine.*

"Take of Tincture of Iodine *one fluidrachm;* Water *one fluidounce.* Mix in a suitable apparatus, and, having applied a gentle heat, let the vapour that arises be inhaled." *Br.*

VERATRIA.

Veratria.

VERATRIA. *U. S., Br. Veratria.*

"Take of Cevadilla, in moderately fine powder, *twenty-four troyounces;* Alcohol, Sulphuric Acid, Magnesia, Water of Ammonia, Purified Animal Charcoal, Water, each, *a sufficient quantity.* Digest the Cevadilla with eight pints of Alcohol for four hours, in a distillatory apparatus, with a heat approaching to boiling, and pour off the liquid. To the residue add eight pints more of Alcohol, mixed with the portion distilled, and, having digested for an hour, pour off the liquid as before. Digest for a third time with the same quantity of Alcohol, together with the portion last distilled, and again pour off. Press the remains of the Cevadilla, mix and strain the liquids, and, by means of a water-bath, distil off the Alcohol. Boil the residue three or four times in Water acidulated with Sulphuric Acid, mix and strain the liquids, and evaporate to the consistence of syrup. Add Magnesia in slight excess, shake the mixture frequently, then express, and wash what remains. Repeat the expression and washing two or three times, and, having dried the residue, digest it with a gentle heat several times in Alcohol, and strain after each digestion. Distil off the Alcohol from the mixed liquids, boil the residue for fifteen minutes in water mixed with a little Sulphuric Acid and Purified Animal Charcoal, and strain. Having thoroughly washed what remains, mix the washings with the strained liquid, evaporate with a moderate heat to the consistence of thin syrup, and drop in sufficient Water of Ammonia to precipitate the Veratria. Lastly, wash the alkaloid with Water and dry it with a gentle heat." *U. S.*

"Take of Cevadilla *two pounds* [avoirdupois]; Distilled Water, Rectified Spirit, Solution of Ammonia, Hydrochloric Acid, of each, *a sufficiency;* Purified Animal Charcoal *sixty grains.* Macerate the Cevadilla with half its weight of boiling Distilled Water, in a covered vessel, for twenty-four hours. Remove the Cevadilla, squeeze it, and dry it thoroughly with a gentle heat. Beat it now in a mortar, and separate the seeds from the capsules by brisk agitation in a deep narrow vessel, or by winnowing it gently on a table with a sheet of paper. Grind

the seeds in a coffee mill, and form them into a thick paste with Rectified Spirit. Pack this firmly in a percolator, and pass Rectified Spirit through it till the Spirit ceases to be coloured. Concentrate the spirituous solution by distillation, so long as no deposit forms; and pour the residue, while hot, into twelve times its volume of cold Distilled Water. Filter through calico, and wash the residue on the filter with Distilled Water, till the fluid ceases to precipitate with Ammonia. To the united filtered liquids add the Ammonia in slight excess, let the precipitate completely subside, pour off the supernatant fluid, collect the precipitate on a filter, and wash it with Distilled Water till the fluid passes colourless. Diffuse the moist precipitate through twelve fluidounces of Distilled Water, and add gradually with diligent stirring sufficient Hydrochloric Acid to make the fluid feebly but persistently acid. Then add the Animal Charcoal; digest at a gentle heat for twenty minutes, filter, and allow the liquid to cool. Add Ammonia in slight excess, and, when the precipitate has completely subsided, pour off the supernatant liquid, collect the precipitate on a filter, and wash it with cold Distilled Water till the washings cease to be affected by nitrate of silver acidulated with nitric acid. Lastly, dry the precipitate first by imbibition with filtering paper, and then by the application of a gentle heat." *Br.*

In the U. S process the first step is to obtain a tincture of cevadilla. In the British process, which is mainly that of the late Edinburgh Pharmacopœia, the use of alcohol is preceded by measures calculated to bring the seeds into a proper state for its action. This is not satisfactorily effected by mere bruising. The seeds are not thus separated from the capsules; and, on account of their elasticity, they cannot be conveniently comminuted in a mortar. The mode of proceeding given in the British Pharmacopœia was suggested by Christison, and is said by him to answer the purpose. In the U. S. process, the tincture, when made, is evaporated to the consistence of an extract. This contains the veratria combined with a vegetable acid, probably the gallic, as it exists in the seeds. From the extract the alkaloid is dissolved by the acidulated water, which at the same time converts it in great measure into a sulphate, a small portion possibly remaining in the solution combined with an excess of the native acid. The magnesia combines with the acids and throws down the veratria, which is then taken up by alcohol, and again yielded in a purer state by evaporation. To purify it still further, it is redissolved in water by the agency of sulphuric acid, is submitted to the action of animal charcoal, and is finally precipitated by ammonia. In the British process, the tincture is concentrated until it begins to let fall a precipitate, and is then poured into water, which throws down the resin and oil with a portion of the colouring matter, and retains the salt of veratria. This is then decomposed by ammonia, and the precipitated veratria is slightly washed with cold water to free it from adhering impurities. If much water is employed in the washing, a considerable portion of the veratria is lost, in consequence of being in some degree soluble in that menstruum in its ordinary impure state. The remaining steps of the British process consist in the purification of the veratria by forming a muriate in solution, decolorizing this by animal charcoal, and again precipitating by ammonia.*

* Mr. James Beatson, manufacturing chemist of the U. S. Naval Laboratory at New York, recommends the following method of preparing veratria as less complicated and troublesome than the officinal, and quite satisfactory in its results. Take 73 pounds (avoirdupois) of cevadilla, rub it upon a coarse wire sieve so as to separate the seeds from the capsules, and reduce the former to a coarse powder by a Swift's drug mill. Pass the capsules also through the mill, separate the finer portion, and mix it with the ground seeds. Moisten the mixture with alcohol, and allow it to stand 12 hours; then introduce it into a displacement apparatus, and pour upon it 30 gallons of alcohol. When a convenient quantity of the liquid has passed, submit it to distillation, and return the distilled alcohol to the displacement apparatus; and proceed in the same way until the cevadilla is thoroughly exhausted. Collect all the alcoholic liquor from the exhausted seeds, and continue the distillation until the tincture has a syrupy consistence. Pour this while hot into eight times its volume of cold water, throw the whole on a calico filter, and wash until the washings cease to indicate the presence of veratria. Mix the washings with what first passed through the filter, and add aqua ammoniæ in excess (about 4 pounds). Wash

The U. S. process is essentially that of M. Couerbe. The veratria obtained by it, though not pure, is sufficiently so for medical use. A drachm of it, in this state, may be procured from a pound of cevadilla. Besides veratria, M. Couerbe states that principles, which he calls respectively *sabadillin* (*sabadillia*) and *veratrin*, are also contained in this product. These are separated in the following manner. Into the solution of impure sulphate of veratria obtained in the above process, nitric acid is to be introduced by drops. This occasions an abundant precipitate, from which the clear liquor is to be decanted. A weak solution of potassa is then to be added to the liquor, and the precipitate which it produces is to be washed with cold water, and treated with boiling alcohol. The substance obtained by evaporating the alcohol yields the *sabadillia* to boiling water, which deposits it upon cooling; a substance, called by M. Couerbe *resini-gum* of sabadilla, remaining in solution. If the residue of the substance, treated as just mentioned with boiling water, be submitted to the action of ether, it yields to this liquid the proper *veratria*, which may be obtained entirely pure by the spontaneous evaporation of the ether. The matter remaining undissolved is the resinous substance which M. Couerbe called *veratrin*. *Sabadillia* is white, crystallizable, insupportably acrid, fusible by heat, readily soluble in hot water,

the precipitated veratria with cold water, and dry it with a very gentle heat. Mr Beatson obtained by this process eleven and a quarter ounces of veratria, but faintly tinged with colouring matter. (*Am. Journ. of Pharm.*, xxvi. 5.)—*Note to the tenth edition.*

M. Auguste Delondre, in a paper upon veratria in the *Journ. de Pharm.* for June, 1855 (p. 417), having stated that he had found the veratria of commerce to contain only from 75 to 85 per cent. of the pure alkaloid; that in the ordinary modes of obtaining it with the aid of heat, much is lost in consequence of its extreme facility of volatilization; and that the operator is from the same cause exposed to excessive irritation of the air-passages, eyes, &c., from its vapours; proposes the following plan of preparing it as the result of many experiments and long attention to the subject.

The powdered cevadilla is treated, by means of percolation, with cold water slightly acidulated with muriatic acid until the liquid which passes strongly reddens litmus paper, when the percolation is finished with pure water. It is known that the cevadilla has been exhausted, when the last liquid which passes gives no precipitate with ammonia. The liquid thus obtained is precipitated by a slight excess of the ammoniacal solution; the grayish precipitate formed is drained and washed; and the washings as well as the decanted liquid are set aside. The precipitate, having been carefully dried and powdered, is treated, in a well-closed bottle, with twice its weight of ether for four hours, with occasional agitation; and the ethereal solution is filtered upon shallow porcelain vessels and allowed to evaporate. A second treatment with half the quantity of ether serves to extract all the alkaloid. The veratria is allowed to dry, and is then carefully detached from the plates so as to avoid unpleasant consequences to the operator, and kept for use. M. Delondre considers his process more productive, cheaper, and less inconvenient than the one generally employed; as the injurious effects of heat are avoided, and there are less frequent solutions.

The alkaloid, *veratrin*, being insoluble in ether, is left behind after the operation of that liquid. It is extracted by alcohol, which, on evaporation, yields a brown resinous matter, from which the veratrin may be obtained by heating it with water acidulated with sulphuric acid, and precipitating by ammonia. It exists, however, in very minute proportion, and is difficult to obtain pure. Its effects have not been determined; but its powder produces sneezing, though much less violently than veratria.

The washings and decanted fluid, which had been set aside, yield on evaporation an extract, which, when dried, and treated with ether, gives a little additional veratria; the sabadillin and resini-gum of M. Couerbe remaining behind. If the residue be dissolved in cold water, and the solution filtered and slowly evaporated, a mixture of crystals of sabadillin and resini-gum is obtained, which it is very difficult to separate.

Commercial veratria may be purified with great facility by means of ether which dissolves the pure alkaloid, leaving the impurities. (*Note to the eleventh edition.*)

Dr. Murray Thomson, of Edinburgh, operates in a similar manner with M. Delondre in exhausting the seeds with water, acidulated with muriatic acid, and in precipitating with ammonia; but, instead of exhausting the precipitate with ether, he uses hot alcohol for the purpose, and then proceeds by evaporating the tincture, treating the residue with acidulated water, decolorizing with a little animal charcoal, and precipitating with ammonia. The alkaloid thus obtained may be rendered purer by again dissolving and precipitating as before. Dr. Thomson has thus obtained veratria in the proportion of 20 grains to an avoirdupois ounce of the seeds. (*Pharm. Journ.*, May, 1861, p. 548.) It is, however, obvious, from what is said in the preceding note, that the veratria of Dr. Thomson contains veratrin. (*Note to the twelfth edition.*)

which deposits it upon cooling, very soluble in alcohol, and wholly insoluble in ether. It is capable of saturating the acids. (*Journ. de Pharm*, xix. 527.) According to Simon, sabadillia is a compound of resinate of soda and resinate of veratria. Fr. Hübschmann confirms the views of Couerbe as to the separate existence of sabadillia. He obtained it by treating the matter considered as veratria with ether, which removed the pure veratria, and left the sabadillia. The latter does not irritate the nostrils like veratria. (*Am. Journ. of Pharm.*, xxv. 133.)

Properties, &c. In the impure state in which it is obtained by either of the above officinal processes, veratria is a grayish or brownish-white powder, without odour, and of a bitter, acrid taste, producing a sense of tingling or numbness in the tongue, and exciting violent sneezing and coryza, when admitted into the nostrils. When pure, it is white, pulverulent, inodorous, extremely acrid, fusible at 200° F., and volatilizable at 360° F. (*Guy*), inflammable, scarcely soluble in cold water, soluble in a thousand parts of boiling water which it renders sensibly acrid, in eleven parts of alcohol of 0·847, and in six parts of ether (Delondre, *Journ. de Pharm.*, xxvii. 421), and capable of neutralizing acids, with several of which, particularly the sulphuric and muriatic, it forms crystallizable salts. As commonly obtained, it is uncrystallizable; but G. Merck, by dissolving it in highly rectified alcohol, and allowing the solution to evaporate spontaneously, obtained fine crystals in the form of rhombic prisms. The quantity obtained in crystals was but a small proportion of the veratria used, which Merck considered to be a mixture of resin with the pure alkaloid, and on this account to be uncrystallizable. (See *Am. Journ. of Pharm.*, xxviii. 134.) The composition of veratria is expressed, according to Couerbe, by the formula $C_{34}H_{22}NO_6$; but Merck, who obtained it crystallized, and therefore pure, gives the formula $C_{64}H_{52}N_2O_{16}$. (*Ibid.*, p. 135.) It may be recognised by its sensible properties, incapacity of crystallization as ordinarily procured, combustibility, fusibility, peculiar solubilities, alkaline reaction, the intense red colour it assumes upon contact with concentrated sulphuric acid, the yellow solution it forms with nitric acid, and the white precipitates which its solution in dilute acetic acid yields with ammonia and the infusion of galls. Chlorine at first colours a solution of its salts yellow, and afterwards produces a white precipitate. (*Cent. Blatt*, June 28, 1856, p. 454.) Compound solution of iodine causes a reddish-brown precipitate, soluble in alcohol. (Fairthorne, *Am. Journ. of Pharm.*, xviii. 212.) According to Trapp, of St. Petersburg, the smallest trace of veratria, if dissolved in highly concentrated muriatic acid, gives a solution which, though colourless at first, becomes red by boiling, and intensely red like permanganate of potassa if the boiling be long continued. (See *Am. Journ. of Pharm.*, Nov. 1863, p. 556.) It is entirely dissipated by a red heat. It is said sometimes to be sophisticated with lime, which is easily detected by incineration, and may be separated by dissolving the powder in diluted alcohol, precipitating by sulphuric acid, filtering, evaporating the alcohol, and precipitating the veratria by ammonia. (*Chem. Gaz.*, Feb. 1845, p. 73.) Mr. John E. Carter, of Philadelphia, found a specimen which he examined to contain 38 per cent. of magnesia. (*Am. Journ. of Pharm.*, Jan. 1858, p. 16.) It may be used either in the uncombined state, or united with acids; as in both forms it produces essentially the same effects.

Medical Properties and Uses. Veratria is locally irritant, and exercises a peculiar influence on the nervous system. Rubbed upon the skin it excites a sensation of warmth and a peculiar tingling. Sometimes an evanescent blush is produced, and still more rarely an eruption upon the skin; but, in general, no decided signs of inflammation are evinced. Upon the denuded cutis, however, veratria and its salts are powerfully irritating; in the mouth and fauces produce an almost insupportable sense of acrimony; and snuffed up the nostrils excite violent sneezing. Magendie states that, when taken internally in the dose of a quarter of a grain, they promptly produce abundant alvine evacuations, and in larger doses provoke more or less violent vomiting. Other experimenters have

observed similar effects. Dr. Turnbull, on the contrary, says that he has very seldom found them to purge, even when largely administered. According to this author, their first effect, when given in moderate doses, is a feeling of warmth in the stomach, gradually extending itself over the abdomen and lower part of the chest, and ultimately to the head and extremities. If the medicine is continued, this feeling of warmth is followed by a sense of tingling, similar to that produced by the external use of the medicine, which manifests itself in different parts of the body, and sometimes over the whole surface, and is frequently accompanied by perspiration and some feeling of oppression. Occasionally also diuresis is produced. A still further continuance of the medicine, or the use of large doses, excites nausea and vomiting. It occasions no narcotic effects. In overdoses it is a violent poison. Dr. J. L. Van Praag has experimented with veratria on the lower animals, and gives as the result of his observations, that it lowers the circulation and respiration, diminishes the irritability of many of the nerves, especially the cutaneous, and produces muscular relaxation; while, at the same time, it frequently vomits, and in large doses purges. The secretion of saliva is much increased, but that of urine little affected. In poisonous doses, before producing the depressing effects above referred to, it accelerates the pulse and respiration, occasions tonic and clonic spasms of the muscles, and exalts the nervous irritability generally. Tetanic stiffening of the limbs, followed by a dancing movement, is a characteristic symptom of poisoning with this alkaloid. Death seems to result from paralysis of the spinal cord. (*B. and F. Medico-chirurg. Rev.*, July, 1855, Am. ed., p. 185; from *Virchow's Archiv.*)

The diseases in which veratria has been employed are chiefly gout, rheumatism, and neuralgia. M. Piedagnel has used it with great supposed advantage in acute articular rheumatism, which he has found generally to get well under its use in seven or eight days. (See *Am. Journ. of Med. Sci.*, N. S., xxvi. 496.) Dr. Turnbull has found it useful also in dropsy, and in diseases of the heart, particularly those of a functional character. He thinks he has also seen it do good in structural diseases of that organ, but chiefly by acting as a diuretic, and thus removing effusion in the pericardium. Prof. Vogt, of Berne, employs it in pneumonia, giving 5 milligrammes (about the thirteenth of a grain) every two hours, and five or six times that amount during the day, increased in insusceptible persons to ten or twelve times the quantity; the dose being continued or increased till vomiting and reduction of the pulse are produced. (See *Am. Journ. of Pharm.*, May, 1860, p. 222.) Dr. D. Martin, of the French army, has experienced great advantage from it in choroido-iritis. (*Ann. de Thérap.*, 1867, p. 16.) Veratria has also been employed in dysmenorrhœa, and in various nervous affections, as paralysis, hooping-cough, epilepsy, hysteria, and disorders dependent upon spinal irritation. From one-twelfth to one-sixth of a grain may be given in the form of pill, and repeated every three hours till the effects of the medicine are experienced. Some prefer the salts for internal use Dr. Turnbull states that the tartrate is least disposed to irritate the stomach. The sulphate or acetate, however, may be used. Any one of these salts may be prepared by treating veratria with water acidulated with the acid to perfect neutralization, and then carefully evaporating to dryness.

But veratria is much more employed externally than by the stomach, and is applicable in this way to all the complaints already mentioned. It has been highly praised as a local application in chronic swellings, stiffening, and induration of the joints, whether from rheumatism, scrofula, or simply from local injuries, as sprains. It may be used either dissolved in alcohol, or rubbed up with lard or other unctuous substance, in the proportion of from five to twenty grains to the ounce. It is advisable that the alkaloid should be dissolved in a little alcohol before being mixed with the lard. Of the ointment thus prepared, a portion of the size of a filbert may be rubbed upon the skin over the part affected, night and morning, from five to fifteen minutes, or until the more urgent symptoms are relieved. Veratria may be used in this way to the amount of from four to eight grains in the day. Care must be taken that the cuticle is sound over the

parts to which it is applied. When the skin is irritable, smaller quantities than those above mentioned must be used.

VINA MEDICATA.

Medicated Wines.

The advantages of wine as a pharmaceutic menstruum are that, in consequence of the alcohol it contains, it dissolves substances insoluble in water, and, to a certain extent, resists their tendency to spontaneous change; while, at the same time, it is less stimulant than rectified or proof spirit, both from its smaller proportion of alcohol, and from the modified state in which this fluid exists in its composition. The acid which it usually contains serves in some instances to increase its solvent power. But most wines, particularly the light varieties, are liable to undergo decomposition; and even the strongest acquire such a liability from the principles which they extract from vegetable substances; so that medicated wines, though they keep much better than infusions or decoctions, are inferior in this respect to the tinctures. The proportion of alcohol, moreover, is not constant; and the preparations, therefore, made with them, are of unequal strength. From these causes, few medicated wines are at present retained. In the choice of wine, the purest and most generous should be selected. Sherry, as directed by the U. S. and British Pharmacopœias, Teneriffe, or Madeira should be preferred. The medicated wines, in consequence of their liability to change, should be prepared in small quantities, without heat, and should be kept in well-stopped bottles in a cool place.

The Wines, formerly officinal, which have been omitted in the present Pharmacopœias, are *Vinum Gentianæ*, Ed., and *Vinum Veratri Albi*, U. S., Lond. W.

VINUM ALOËS. *U. S., Br. Wine of Aloes.*

"Take of Socotrine Aloes, in fine powder, *a troyounce;* Cardamom [seeds], in moderately fine powder, Ginger, in moderately fine powder, each, *sixty grains;* Sherry Wine *a pint.* Macerate for seven days, with occasional agitation, and filter through paper." *U. S.*

"Take of Socotrine Aloes *one ounce and a half* [avoirdupois]; Cardamom Seeds, freed from the pericarps and bruised, Ginger, in coarse powder, of each, *eighty grains;* Sherry *two pints* [Imperial measure]. Macerate for seven days in a closed vessel, with occasional agitation; filter the liquor, and add sufficient Sherry to make two pints [Imp. meas.]." *Br.*

The wine of aloes is a warm stomachic purgative, useful in constipation dependent on a want of due irritability of the alimentary canal, and in complaints connected with this state of the bowels. It has long been used in chlorosis, amenorrhœa, dyspepsia, gout, paralysis, &c. It is said to leave behind it a more lax condition of the bowels than most other cathartics. The dose as a stomachic is one or two fluidrachms, as a purgative from half a fluidounce to a fluidounce. W.

VINUM ANTIMONII. *U. S.* Vinum Antimoniale. *Br. Antimonial Wine. Wine of Antimony.*

"Take of Tartrate of Antimony and Potassa *thirty-two grains;* Boiling Distilled Water *a fluidounce;* Sherry Wine *a sufficient quantity.* Dissolve the Salt in the Distilled Water, and, while the solution is hot, add sufficient Sherry Wine to make it measure a pint." *U. S.*

"Take of Tartarated Antimony *forty grains;* Sherry *one pint* [Imperial measure]. Dissolve." *Br.*

In the first edition of the United States Pharmacopœia, the proportion of tartar emetic was four grains to the fluidounce of wine. In the revision of 1830, the quantity was reduced to two grains, and, as this was very nearly the proportion directed by the British Colleges, the highly important object was accom-

plished, of uniformity in the strength of this very popular preparation. The seeming discrepancy between the British formula and that of the U. S. Pharmacopœia will disappear, when it is considered that the Imperial pint, employed in the former, contains twenty fluidounces, each very nearly equal to the fluidounce of the ordinary apothecaries' measure. The U. S. officinal name was adopted as most convenient, sufficiently expressive, and in accordance with the nomenclature of several other metallic preparations, such as *Emplastrum Ferri*, *Mistura Ferri Composita*, &c.

Difficulty is often experienced in effecting a solution of tartar emetic in wine; and precipitation is apt to occur after the solution has been effected. These results are attributable either to impurity in the antimonial salt, which frequently contains bitartrate of potassa and various insoluble substances, or to inferiority in the character of the wine, which holds in solution vegetable principles that form insoluble compounds with the teroxide of antimony. Dr. Paris stated that he had seen the decomposition of the tartar emetic so complete, that no traces of the salt could be detected in the supernatant liquid. The difficulty is not avoided by the plan adopted in the U. S. Pharmacopœia, of first dissolving the antimonial in water, and then adding the wine; for, even allowing that the solution may be accomplished, the same ingredients are present, and their mutual reaction must ultimately result in the same effects. The proper course is to select perfectly pure crystallized tartar emetic, and sound Sherry or Teneriffe wine, which make a permanent solution. To obviate the risk of decomposition, the Dublin College directed water and rectified spirit in about the proportion in which these exist in the wines just mentioned. The only objection to this menstruum is the want of colour, which renders the preparation liable to be confounded with less active liquids.

The advantages of antimonial wine are, that it affords the means of administering minute doses of tartar emetic, and is more permanent than an aqueous solution of that salt, which is liable to spontaneous decomposition. It is usually administered in small doses as a diaphoretic or expectorant, or as an emetic in infantile cases. When a considerable quantity of tartar emetic is requisite, it should always be given in extemporaneous aqueous solution. The dose of the wine, as an expectorant or diaphoretic, is from ten to thirty drops, given frequently; as an emetic for children, from thirty drops to a fluidrachm, repeated every fifteen minutes till it operates.

Off. Prep. Mistura Glycyrrhizæ Composita, *U. S.* W.

VINUM AURANTII. *Br. Orange Wine.*

"Wine made in Britain, by the fermentation of a Saccharine Solution to which the fresh Peel of the Bitter Orange has been added." *Br.*

This preparation has a taste and aroma derived from the bitter orange peel, is slightly acid to test paper, and contains about 12 per cent. of alcohol. It is a mild, pleasant aromatic tonic, but is used rather as a vehicle of other tonics than by itself.

Off. Prep. Vinum Ferri Citratis, *Br.;* Vinum Quiniæ, *Br.* W.

VINUM COLCHICI RADICIS. *U. S.* Vinum Colchici. *Br. Wine of Colchicum Root.*

"Take of Colchicum Root, in moderately fine powder, *twelve troyounces;* Sherry Wine *a sufficient quantity.* Moisten the powder with four fluidounces of Sherry Wine, pack it firmly in a conical percolator, and gradually pour Sherry Wine upon it until two pints of filtered liquid are obtained." *U. S.*

"Take of Colchicum Corm, sliced, dried, and bruised, *four ounces* [avoirdupois]; Sherry *one pint* [Imperial measure]. Macerate the Colchicum in the Wine for seven days in a closed vessel, with occasional agitation, press and strain through calico; then add sufficient Sherry to make up one pint [Imp. meas.]." *Br.*

This is intended to be a saturated vinous tincture of colchicum. As the colchicum bulb imported into the United States is of variable strength, the only

method by which an active preparation can be ensured, is to employ a large quantity of it in proportion to that of the menstruum. If the former should happen to be in excess, no other injury could result than a slight pecuniary loss; while a deficiency in the strength of the preparation would frequently be of serious detriment in urgent cases of disease. A wine made from the fresh bulb is occasionally imported from England, and is thought by some to be more efficacious than our officinal preparation; but we have seldom been disappointed in obtaining the effects of colchicum from the wine prepared according to the directions of the U. S. Pharmacopœia. The dose of the officinal wine is from ten minims to a fluidrachm, repeated three or four times a day, or more frequently in severe cases, till its effects are experienced. In gout it is frequently given in connection with magnesia and its sulphate; and in neuralgic cases we have found much advantage from combining it with the solution of sulphate of morphia, especially when we have desired to give it a direction rather to the skin than the bowels. It has been employed externally with asserted advantage in rheumatism. In overdoses it may produce fatal effects. Death is said to have occurred in one instance from two drachms and a half of the wine; but much more would probably in general be requisite to produce this result. W.

VINUM COLCHICI SEMINIS. *U. S. Wine of Colchicum Seed.*

"Take of Colchicum Seed, in moderately coarse powder, *four troyounces;* Sherry Wine *two pints.* Macerate for fourteen days, with occasional agitation; then express, and filter through paper." *U. S.*

As the seeds of colchicum are less liable to injury than the bulb, and are, therefore, of more uniform strength, there is not the same necessity for preparing a saturated tincture. Dr. Williams, who introduced the seeds into use, supposed that their active properties resided in their coating, and that it was, therefore, not advisable to bruise them in preparing the wine or tincture. But this has been shown to be an error by the experiments of Mr. Bonnewyn, who found a larger proportion of colchicia in a tincture of the bruised than in one of the unbruised seeds. (See *Am. Journ. of Pharm.*, xxvi. 120.) In order that the seeds may be properly comminuted, Mr. Maisch recommends that they should be macerated for two or three days in a portion of the wine, before being bruised. (*Ibid.*, xxviii. 514.) The dose is from thirty minims to two fluidrachms. Two fluidounces have proved fatal. W.

VINUM ERGOTÆ. *U.S. Wine of Ergot.*

"Take of Ergot, in moderately fine powder, *four troyounces;* Sherry Wine *a sufficient quantity.* Moisten the powder with half a fluidounce of Sherry Wine, pack it in a conical percolator, and gradually pour Sherry Wine upon it until two pints of filtered liquid are obtained." *U. S.*

In a certain number of copies of the existing edition of the U. S. Pharmacopœia first issued from the press, *two* troyounces of the ergot were, no doubt inadvertently, directed instead of *four;* the intention being that the Wine should continue to have the same strength as that of 1850, in the preparation of which two ounces were directed; but the fact being overlooked that the quantity of the menstruum was only one pint, while in the present formula it is two pints. The error, however, was corrected; and in the copies now issued four ounces are ordered, as above stated. The large proportion of fixed oil in ergot interferes with the solvent action of the menstruum, unless the grains are finely powdered. It is, therefore, best to employ the ergot in this process well powdered, instead of merely bruised, as was formerly officinally directed.

The dose of this wine is for a woman in labour two or three fluidrachms; for other purposes, one or two fluidrachms, to be repeated several times a day, and gradually increased if necessary. W.

VINUM FERRI. *Br. Wine of Iron.*

"Take of Fine Iron Wire (about No. 35) *one ounce* [avoirdupois]; Sherry *one pint* [Imperial measure]. Macerate for thirty days in a closed vessel, the

Iron being almost but not quite wholly immersed in the Wine, and the vessel frequently shaken, and the stopper removed; then filter." *Br.*

When wine is made to react on metallic iron with presence of air, the metal is oxidized, and then unites with the excess of acid of the bitartrate of potassa, which is the characteristic salt of wines. The ferruginous salt, therefore, formed is the tartrate of iron and potassa, or tartarated iron of the Br. Pharmacopœia; and this was the old method of preparing the Wine of Iron. But it is obvious that the strength in iron cannot be entirely uniform, as the quantity dissolved must depend on the proportion of the bitartrate in the wine, which is variable, and on various circumstances of the manipulation. In consideration of these objections, it was thought best, in the Br. formula of 1864, to substitute a simple solution in the wine of the tartrate of iron and potassa already formed, and to abandon the old tedious formula. But it is obvious that a solution of the ferruginous salt in wine is not exactly the same as the wine of iron prepared with the metal, as it contains the bitartrate of potassa unaltered. For this, or other reasons, the Br. Pharmacopœia has returned to the old method. The dose of the wine of iron is from one to four fluidrachms. W.

VINUM FERRI CITRATIS. *Br. Wine of Citrate of Iron.*

"Take of Citrate of Iron and Ammonia *one hundred and sixty grains;* Orange Wine *one pint* [Imperial measure]. Dissolve, and let the solution remain for three days in a closed vessel, shaking it occasionally; afterwards filter. Dose one to four fluidrachms." *Br.*

VINUM IPECACUANHÆ. *U.S., Br. Wine of Ipecacuanha.*

"Take of Ipecacuanha, in moderately fine powder, *two troyounces;* Sherry Wine *a sufficient quantity.* Moisten the powder with half a fluidounce of Sherry Wine, pack it moderately in a conical percolator, and gradually pour Sherry Wine upon it until two pints of filtered liquid are obtained." *U. S.*

"Take of Ipecacuanha, bruised, *one ounce* [avoirdupois]; Sherry *one pint* [Imperial measure]. Macerate for seven days in a closed vessel, with occasional agitation, strain, press, and filter; then add sufficient Sherry to make one pint [Imp. meas.]" *Br.*

The preparations of the two Pharmacopœias are not of the same strength; the U. S. wine containing the virtue of 30 grains, the British of only somewhat more than 20 grains in a fluidounce. In the preparation of the British Pharmacopœia, the strength of this wine was reduced almost one-third. Wine of ipecacuanha possesses all the medical properties of the root, and may be used as a substitute when it is desirable to administer the medicine in the liquid form. As it is milder, without being less efficacious than antimonial wine, it is in some instances preferable as an emetic for infants, especially when the antimonial, as not unfrequently happens, is disposed to irritate the bowels. It is much used as an expectorant and diaphoretic; and the effects of the Dover's powder may be obtained by combining it with laudanum, or other liquid preparation of opium. The dose as an emetic for an adult is a fluidounce; as an expectorant and diaphoretic, from ten to thirty minims. A fluidrachm may be given as an emetic to a child one or two years old, and repeated every fifteen minutes till it operates. W.

VINUM OPII. *U.S., Br. Wine of Opium. Sydenham's Laudanum.*

"Take of Opium, dried, and in moderately fine powder, *two troyounces;* Cinnamon, in moderately fine powder, Cloves, in moderately fine powder, each, *sixty grains;* Sherry Wine *a sufficient quantity.* Mix the powders with fifteen fluidounces of Sherry Wine, and macerate for seven days, with occasional agitation; then transfer the mixture to a conical percolator, and, when the liquid has passed the surface, gradually pour on Sherry Wine until a pint of filtered liquid is obtained." *U.S.*

"Take of Extract of Opium *one ounce* [avoirdupois]; Cinnamon Bark, bruised, Cloves, bruised, of each, *seventy-five grains;* Sherry *one pint* [Impe-

rial measure]. Macerate for seven days in a closed vessel, with occasional agitation, and filter." *Br.*

The wine made according to the directions of the U. S. Pharmacopœia is a saturated vinous tincture of opium. It contains about the same proportions of the ingredients as the *laudanum of Sydenham*, from which it differs only in wanting a drachm of saffron. The aromatic additions are thought to adapt it to certain states of the stomach or system, in which laudanum is found to produce unpleasant effects. On being long kept it deposits insoluble matter, a sample of which M. Bihot, of Malines, has shown to consist mainly of narcotina, with possibly a little codeia, without any discoverable trace of morphia. (*Journ. de Pharm.*, xxx. 200.) Mr. Ware recommended it as a local application to the eye, in the latter stages of ophthalmia, when the vessels of the conjunctiva still remain turgid with blood. Two or three drops are introduced into the eye every morning till the redness disappears. The dose of the wine of opium is the same as that of the tincture.* W.

VINUM QUINIÆ. *Br. Wine of Quinia.*

"Take of Sulphate of Quinia *twenty grains;* Citric Acid *thirty grains;* Orange Wine *one pint* [Imperial measure]. Dissolve first the Citric Acid, and then the Sulphate of Quinia in the Wine; allow the solution to remain for three days in a closed vessel, shaking it occasionally; and afterwards filter. The dose is from half a fluidounce to a fluidounce." *Br.*

VINUM RHEI. *U. S., Br. Wine of Rhubarb.*

"Take of Rhubarb, in moderately coarse powder, *two troyounces;* Canella, in moderately fine powder, *sixty grains;* Sherry Wine *fourteen fluidounces;* Diluted Alcohol *a sufficient quantity.* Mix two fluidounces of Diluted Alcohol with the Sherry Wine, and moisten the powders, previously rubbed together, with half a fluidounce of the mixture; then transfer them to a conical percolator, and gradually pour upon them the remainder of the mixture, and afterwards Diluted Alcohol until a pint of filtered liquid is obtained." *U. S.*

"Take of Rhubarb Root, in coarse powder, *one ounce and a half* [avoirdupois]; Canella Alba Bark, in coarse powder, *sixty grains;* Sherry *one pint* [Imperial measure]. Macerate for seven days in a closed vessel, with occasional agitation, then strain, press, filter, and add sufficient Sherry to make one pint [Imp. meas.]." *Br.*

This is a warm cordial laxative, applicable to debilitated conditions of the system or alimentary canal requiring evacuation of the bowels. The dose is from one to four fluidrachms or more, according to the amount of effect required, and the condition of the patient. W.

VINUM TABACI. *U. S. Wine of Tobacco.*

"Take of Tobacco, in moderately fine powder, *a troyounce;* Sherry Wine *a pint.* Macerate for seven days, with occasional agitation; then express, and filter through paper." *U. S.*

The dose of the wine of tobacco, as a diuretic, is from ten to thirty minims. It is very seldom used. W.

* *Rousseau's laudanum* is a tincture of opium made with very weak alcohol, which may be classed with propriety along with the above preparation. It is made according to the following formula. "Take of white honey *twelve ounces;* warm water *three pounds.* Having dissolved the honey, set the solution aside in a warm place; and, as soon as fermentation begins, add of selected opium *four ounces*, previously dissolved in *twelve ounces* of water. Allow the mixture to stand for a month at the temperature of 24° Reaumur (86° F.); then strain, filter, and evaporate to *ten ounces;* finally strain, and add *four ounces and a half* of alcohol of 20° B. Seven drops contain about a grain of opium." (*Pharmacop. Univers.*, ii. 265.)

ZINCUM.

Preparations of Zinc.

Of the officinal Preparations of Zinc formerly treated of under this head, *Sulphate of Zinc* has been transferred, in the U. S. Pharmacopœia, to the Materia Medica catalogue; *Prepared Calamine*, U. S., Lond., Ed., has been omitted in the present Pharmacopœias; and *Solution of Chloride of Zinc*, Dub., has been placed with the Liquores or Solutions.

ZINCI ACETAS. *U. S., Br. Acetate of Zinc.*

"Take of Acetate of Lead *twelve troyounces;* Zinc, granulated, *nine troyounces;* Distilled Water *a sufficient quantity.* Dissolve the Acetate of Lead in three pints of Distilled Water, and filter. Then add the Zinc to the solution, and agitate the mixture occasionally, in a stopped bottle, for five or six hours, or until the liquid yields no precipitate with a solution of iodide of potassium. Filter the liquid, evaporate it with a moderate heat to one-fifth, acidulate it slightly with acetic acid, and set it aside to crystallize. Pour off the liquid, and dry the crystals on bibulous paper. Should the crystals be coloured, dissolve them in a pint and a half of Distilled Water, and, having heated the solution to ebullition, drop into it, while boiling, recently precipitated carbonate of zinc, in successive portions, until a small quantity of the liquid, being filtered, passes colourless. Then filter the liquid, acidulate it slightly with acetic acid, and evaporate that crystals may form." *U. S.*

"Take of Carbonate of Zinc *two ounces* [avoirdupois]; Acetic Acid *five fluidounces*, or *a sufficiency;* Distilled Water *six fluidounces.* Add the Carbonate of Zinc in successive portions to three [fluid]ounces of the Acetic Acid, previously mixed with the Water in a flask; heat gently, add by degrees the remainder of the Acid till the carbonate is dissolved; boil for a few minutes, filter while hot, and set it aside for two days to crystallize. Decant the mother-liquor; evaporate to one-half, and again set it aside for two days to crystallize. Place the crystals in a funnel to drain, then spread them on filtering paper on a porous tile, and dry them by exposure to the air at ordinary temperatures." *Br.*

In the *U. S.* process the lead is wholly precipitated by the zinc, which forms with the acetic acid the acetate of zinc in solution. In order to be sure that the solution is entirely free from lead, it is tested with iodide of potassium, which will produce a yellow precipitate if any of the lead remain unprecipitated. The crystals of acetate of zinc, as first obtained, are apt to be coloured with iron. Should this be the case, a boiling solution of them in distilled water is to be treated by the addition of successive portions of precipitated carbonate of zinc, until a small quantity of the liquid, being filtered, passes colourless. The zinc of the carbonate of zinc precipitates the iron, and takes its place in the solution; and the iron is known to be all removed, when a portion of the solution is found, upon trial, to filter colourless. This mode of purifying the acetate of zinc from iron was suggested by Professor Procter, and was adopted in the U. S. Pharmacopœia of 1850, in place of the mode by means of a solution of chlorinated lime, which he found to separate the iron imperfectly. The necessary carbonate of zinc may be obtained extemporaneously, by converting one-thirtieth of the coloured solution of the acetate into carbonate by precipitating it with carbonate of potassa in slight excess, as originally proposed by Prof. Procter. The precipitated carbonate, first washed from acetate of potassa, is added in the state of magma to the coloured solution, boiling hot. During the evaporation of the solution of the acetate of zinc, a small portion of the acetic acid is lost; and hence the necessity of acidulating with a few drops of acetic acid before crystallizing. In the *British* process, there is simply a decomposition of the carbonate of zinc by acetic acid, with the formation of acetate of zinc in solution, and the escape of carbonic acid. Though not an economical process, it has the recommendation of being easily performed, and of yielding a pure

product. In relation to the acetate of zinc, see a paper by Mr. Ambrose Smith, contained in the *Amer. Journ. of Pharm.* (vii. 14).

Properties, &c. Acetate of zinc, when carefully crystallized, is in colourless hexagonal plates, which effloresce in a dry air. As found in the shops it is in white micaceous crystals. It is very soluble in water, moderately so in rectified spirit, and has an astringent, metallic taste. The solution yields white precipitates with ferrocyanide of potassium and hydrosulphuret of ammonia. The precipitate thrown down by ammonia from the pure salt is entirely redissolved by an excess of the precipitant; but, if sesquioxide of iron be present, it will be left undissolved. Acetate of zinc is decomposed by the mineral acids, with the escape of acetous vapours. It consists of one eq. of acetic acid 51, one of protoxide of zinc 40·3, and two of water 18 = 109·3 ($ZnO,C_4H_3O_3 + 2HO$).

Medical Properties. Acetate of zinc is used almost exclusively as a local remedy. It is employed principally as an astringent collyrium in ophthalmia, and as an injection in gonorrhœa, after the acute stage in these affections has passed. The strength of the solution, usually prescribed, is one or two grains to a fluidounce of distilled water. B.

ZINCI CARBONAS PRÆCIPITATA. *U. S.* Zinci Carbonas. *Br.* *Precipitated Carbonate of Zinc. Carbonate of Zinc.*

"Take of Sulphate of Zinc, Carbonate of soda, each, *twelve troyounces;* Water *eight pints.* Dissolve the salts separately, with the aid of heat, each in four pints of the Water. Then mix the solutions, and, having stirred the mixture, set it by that the powder may subside. Lastly, having poured off the supernatant liquid, wash the precipitate with hot water until the washings are nearly tasteless, and dry it with a gentle heat." *U. S.*

"Take of Sulphate of Zinc *ten ounces* [avoirdupois]; Carbonate of Soda *ten ounces and a half* [avoird.]; Boiling Distilled Water *a sufficiency.* Dissolve the Carbonate of Soda with a pint [Imperial measure] of the Water in a capacious porcelain vessel, and pour into it the Sulphate of Zinc also dissolved in a pint [Imp. meas.] of the Water, stirring diligently. Boil for fifteen minutes after effervescence has ceased; and let the precipitate subside. Decant the supernatant liquor, pour on the precipitate three pints of boiling Distilled Water, agitating briskly; let the precipitate again subside; and repeat the process of affusion of hot Distilled Water and subsidence, till the washings are no longer precipitated by chloride of barium. Collect the precipitate on calico, let it drain, and dry it with a gentle heat." *Br.*

In view of the impurities and frequent falsification of the native carbonate of zinc, the revisers of the U. S. Pharmacopœia conceived that it would be best to discard altogether the old preparation, which in the edition of 1850 was still retained under the changed name of *Calamina*, and to recognise exclusively the new one first adopted in 1850. In the U. S. formula a double decomposition takes place between the salts employed, resulting in the formation of sulphate of soda in solution, and carbonate of zinc which precipitates. Carbonate of soda is preferable to carbonate of potassa for decomposing the sulphate; since the former gives rise to sulphate of soda, which is more easily washed away than sulphate of potassa derived from the latter. Boiling water is properly used in the process, in order to obtain a pulverulent precipitate, which is readily washed. If cold solutions are used, a gelatinous precipitate is formed, which is washed with difficulty. The present *British* formula is essentially the same with that of the U. S. Pharm., having superseded the Dublin process, in which the reacting salts were chloride of zinc and carbonate of soda.

Properties, &c. Precipitated carbonate of zinc is in the form of a very soft, loose, white powder, resembling magnesia alba. It dissolves in dilute sulphuric acid with effervescence, forming a solution having the characters of a solution of sulphate of zinc. If adulterated with chalk, it will be only partly soluble in this acid. Precipitated carbonate of zinc is often sold under the incorrect name of flowers of zinc, a name which properly belongs only to the oxide, as obtained

by combustion. When obtained from boiling solutions of sulphate of zinc and carbonate of soda, it has the composition, according to Schindler and Lefort, $8ZnO,3CO_2 + 6HO$. (*Journ. de Pharm.*, 3e sér., xi. 329.) According to the Br. Pharmacopœia, it consists, as thus prepared, of one eq. of carbonate and two eqs. of oxide of zinc, with three eqs. of water ($ZnO,CO_2 + 2ZnO + 3HO$). The basic character of the salt is explained by the fact that effervescence of carbonic acid takes place on mixing the solutions. It is employed for the same purposes as prepared calamine, and is gradually superseding the spurious article usually sold under that name. The U. S. Pharmacopœia orders a cerate made from it as a substitute for calamine cerate. (See *Ceratum Zinci Carbonatis.*)

Off. Prep. Zinci Acetas, *Br.;* Ceratum Zinci Carbonatis, *U. S.;* and Zinci Oxidum. B.

ZINCI CHLORIDUM. *U. S., Br. Chloride of Zinc. Butter of Zinc.*

"Take of Zinc, in small pieces, *two troyounces and a half;* Nitric Acid, Prepared Chalk, each, *sixty grains;* Muriatic Acid, Water, each, *a sufficient quantity.* To the Zinc, in a glass or porcelain vessel, add gradually sufficient Muriatic Acid to dissolve it; then strain the solution, add the Nitric Acid, and evaporate to dryness. Dissolve the dry mass in five fluidounces of the Water, add the Chalk, and allow the mixture to stand for twenty-four hours. Then filter into an evaporating basin, and again evaporate to dryness. Lastly, fuse the dry mass in the basin, pour out the liquid on a flat stone, and, when it has congealed, break the mass in pieces, and keep the fragments in a well-stopped bottle." *U. S.*

"Take of Granulated Zinc *sixteen ounces* [avoirdupois]; Hydrochloric Acid *forty-four fluidounces* [Imperial measure]; Solution of Chlorine *a sufficiency;* Carbonate of Zinc *half an ounce* [avoird.], or *a sufficiency;* Distilled Water *one pint* [Imp. meas.]. Put the Zinc into a porcelain basin, add by degrees the Hydrochloric Acid previously mixed with the Water, and aid the action by gently warming it on a sand-bath until gas is no longer evolved. Boil for half an hour, supplying the water lost by evaporation, and allow it to stand on a cool part of a sand-bath for twenty-four hours, stirring frequently. Filter the product into a gallon bottle, and pour in the Solution of Chlorine by degrees, with frequent agitation, until the fluid acquires a permanent odour of chlorine. Add the Carbonate of Zinc, in small quantities at a time, and with renewed agitation, until a brown sediment appears. Filter through paper into a porcelain basin, and evaporate until a portion of the liquid, withdrawn on the end of a glass rod and cooled, forms an opaque white solid. Pour it out now into proper moulds, and when the salt has solidified, but before it has cooled, place it in closely stoppered bottles." *Br.*

In the U. S. process the chloride of zinc is first formed in solution by dissolving zinc in muriatic acid. The nitric acid added sesquioxidizes any iron which may have existed as an impurity in the zinc. By evaporating to dryness and redissolving in water, most of the sesquioxide of iron is left behind. Lastly, in order to remove any remains of iron, a small portion of chalk is added, which precipitates it as a sesquioxide; and the mixture, after standing, is filtered and evaporated to dryness. This process is the same as that of the French Codex. The British agrees with the U. S. process in first preparing the chloride of zinc in solution; but differs in the mode of getting rid of the iron. Instead of nitric acid it uses chlorine, which combines with the iron to form a chloride; and, carbonate of zinc being then added, the zinc combines with the chlorine to increase the product of chloride of zinc, while the oxygen of the oxide of zinc, the carbonic acid, and the iron unite as the carbonate of iron, which is deposited. As this preparation is used chiefly as a caustic, it is melted and cast into moulds as the last step in the Br. process. In relation to this chloride, the reader is referred to a paper by Mr. B. J. Crew in the *Am. Journ. of Pharm.*, May, 1853, p. 203.

M. Rhighini prepares this chloride by double decomposition between solutions of chloride of barium and sulphate of zinc. Sulphate of baryta is precipi-

tated, and chloride of zinc remains in solution, from which it is obtained in white flaky crystals by due evaporation.

Properties. Chloride of zinc is generally in white, amorphous or granulated masses, sometimes in cylinders or tablets, and very deliquescent. When pure, it is wholly soluble in water, alcohol, and ether; but, as prepared by the U. S. formula, it contains some oxychloride, which is left undissolved by water. According to M. Lassaigne, commercial chloride of zinc sometimes contains as much as 12 per cent. of arseniate of zinc, which, being insoluble in solution of chloride of zinc, will be left undissolved when the chloride is treated with water. (*Phillips's Trans. of the Lond. Pharm.*, 1851, p. 375.) Its solution yields with nitrate of silver a white precipitate (chloride of silver) insoluble in nitric acid; and with ammonia and potassa a white precipitate, soluble in those reagents when added in excess. The carbonates of potassa and soda also throw down white precipitates, which are not dissolved by an excess of the precipitants. Chloride of zinc has a strong tendency to combine with organic bases, forming crystallizable compounds, as with strychnia, morphia, quinia, cinchonia, &c.; in this respect resembling certain other metallic chlorides, as of platinum, palladium, gold, and mercury. (*Journ. de Pharm.*, 4e sér., iii. 56.) When exposed to heat chloride of zinc first melts and then sublimes. When pure it gives white precipitates with ferrocyanide of potassium and hydrosulphuret of ammonia. A blue precipitate with the former test would indicate iron, a dark one with the latter, lead. It consists of one eq. of zinc 32·3, and one of chlorine 35·5 = 67·8.

Medical Properties and Uses. This chloride was introduced into medicine by Dr. Papenguth, of St. Petersburg, and subsequently recommended by Prof. Hancke, of Breslau, and Dr. Canquoin, of Paris. Internally it has been given as an alterative and antispasmodic in scrofula, epilepsy, chorea, and, combined with hydrocyanic acid, in facial neuralgia. Its chief use, however, has been as an escharotic, applied to cancerous affections, and to ulcers of an anomalous and intractable character. When thus used, it not only destroys the diseased structure, but excites a new action in the surrounding parts. As a caustic it has the advantage of not causing constitutional disorder from absorption, an effect which is sometimes produced by the arsenical preparations.

Dr. Canquoin prepares the chloride of zinc, as an escharotic, by thoroughly and quickly mixing it with wheat flour and water into a paste of four different strengths, containing severally an ounce of the chloride, incorporated with two, three, four, and five ounces of flour; fifteen drops of water being added for every ounce of flour, or sufficient to form the paste. It is applied in cakes from a twelfth to a third of an inch in thickness, and produces an eschar more or less deep (from a line to an inch and a half), according to the thickness and strength of the paste, the length of the application, and the nature of the part acted on. The strongest paste is applied to lardaceous and fibro-cartilaginous structures; the second to carcinomatous tumours, and very painful cancers which have not much thickness, and the third to cancerous affections in persons who have a dread of the use of the knife. These preparations, applied to the skin denuded of its cuticle by means of a blister, excite in a few minutes a sensation of heat, and afterwards violent burning pain. The eschar, which is white, thick, and very hard, falls off, with the aid of an emollient poultice, between the eighth and twelfth days. To destroy thick cancerous tumours, having an uneven surface, and situated in fleshy parts, Dr. Canquoin uses a caustic formed of one part of chloride of zinc, half a part of chloride of antimony, and two and a half parts of flour, made into a paste with water. In all cases, the caustic is to be reapplied, after the falling off of the eschar, until the whole morbid structure is destroyed. When the skin is unbroken, it is now usual to destroy, not merely the cuticle, but the true skin also, by means of the acid nitrate of mercury, to the extent desired for the chloride to operate. This is applied, spread on lint, and the dressing is covered with a portion of cotton wadding, to absorb any discharge, and to preserve a uniform temperature. The surrounding skin should be protected from the caustic by a thickly-spread dressing of simple cerate, containing as much chloroform as it

will take up, as recommended by Dr. E. S. Haviland, of London. M. Bonnet has applied the paste of chloride of zinc to the treatment of aneurism. He has reported the complete cure of one case of subclavian aneurism from a penetrating wound, by a continued series of applications of the paste. Every two or three days, the superficial layers of the slough were removed by a bistoury. At the end of the second month, the eschar began to detach itself without any hemorrhage, and the clot came away with the eschar. Chloride of zinc has also been used successfully by MM. Bonnet and Gensoul in the treatment of aneurism by anastomosis. (*Med. Times and Gaz.*, July 23, 1853.) Instead of flour, Dr. Alex. Ure, of Glasgow, mixes the chloride with pure anhydrous sulphate of lime in impalpable powder. He states that this has the advantages of furnishing a porous medium from which the escharotic gradually exudes into the morbid structure, and of forming afterwards, by acquiring a firmer consistence, an impervious case for the eschar. Mr. Cock, of Guy's Hospital, has imitated this mode of preparing the chloride, so as to form a caustic which may be limited in its action, and does not run. It may be prepared as a caustic seton, by thickly covering a waxed cotton wick with Dr. Canquoin's caustic paste, and then rolling it out in the form of a cylinder, according to the plan of M. Ancrénis, of Lyons. A thread is wound spirally round the cylinder to give it firmness. Mr. Calloway, of Guy's Hospital, has employed the chloride of zinc with considerable success in the treatment of nævi materni. He rubs it, at intervals, on the part until the skin becomes slightly discoloured. The late Mr. Guthrie used it with advantage for penetrating the hard case of new bone which forms over a sequestrum, in order to expose the latter, and permit its convenient extraction.

Chloride of zinc is an ingredient in the complex caustic formed of chlorides, employed by Prof. Landolfi, of Naples, in the treatment of cancer. For his formula, see *pages* 181–2. This treatment was reported on unfavourably, in 1856, by a committee of the French Academy of Medicine, headed by M. Broca. (See *Ranking's Abstract*, no. 24, p. 100.) The cancer caustic of Dr. J. W. Fell consists of chloride of zinc, mixed with bloodroot, and made into a paste with flour and water. It is not supposed that the bloodroot has any decided caustic effect; so that the local treatment of cancer by Dr. Fell is virtually the same as that recommended in certain cases by Dr. Canquoin.

Chloride of zinc, with a view to its escharotic effect, may be formed extemporaneously by means of *galvanism*, on the plan recommended by an English physician, Dr. Thomas Smith. A simple galvanic circle is formed by riveting a disc of zinc, of the size of the eschar desired, to a disc of silver of equal size; the pair being excited by a piece of spongio-piline, placed on the silver, and moistened with a solution of common salt. The little battery is then fixed upon the skin by means of strips of adhesive plaster. Once in twelve hours it must be removed, and washed in salt and water, and then reapplied. By the electrolysis of the common salt chlorine is liberated, which, combining with the zinc, converts it to a certain extent into the chloride. This, acting on the skin, exercises its caustic effect; and at the end of twelve days a white eschar is formed. This mode of forming an issue has, according to Dr. Smith, the advantage of being less painful than those usually employed.

According to M. E. Robiquet, chloride of zinc may be made into a very malleable, pliable caustic, susceptible of taking any shape desired by the surgeon, by melting it with an equal weight of gutta-percha. (See *page* 446.)

For internal exhibition, the most convenient form is a solution in the spirit of ether, in the proportion of half an ounce to three fluidounces. Of this from four to eight drops may be given twice a day. Dr. Lloyd, of London, has found chloride of zinc useful as an injection in the acute stage of gonorrhœa, made of the strength of about two grains to three fluidounces of distilled water, and employed once in five or six hours. A solution of one grain to the fluidounce is used by Mr. Critchett, of the Royal Ophthalmic Hospital, London, as a collyrium in vascular and thickened conjunctiva, forming a sort of gleet of the eye.

In overdoses chloride of zinc acts as a corrosive poison, producing burning

pain in the gullet and stomach, nausea and vomiting, cold sweats, depression of the pulse, and cramps of the legs. According to Dr. T. Stratton, surgeon R. N., who treated two cases of poisoning with this chloride at Montreal, the best antidotes are the carbonated alkalies, which act by converting the poison into carbonate of zinc. Should the alkalies not be at hand, a solution of common soap should be immediately and freely given. (*Med. Exam.*, Feb. 1849; from the *Brit. Am. Journ. of Med. and Phys. Sci.*) Dr. Letheby reports a fatal case of poisoning by this chloride occurring in a child. The form of chloride swallowed was Burnett's disinfecting fluid. (See *Liquor Zinci Chloridi.*) Its local effect was that of a corrosive on the lips, mouth, and fauces. Among the constitutional effects were paralysis of the voluntary muscles, coldness of the surface, dilated pupil, and coma.*

ZINCI OXIDUM. *U. S., Br. Oxide of Zinc.*

"Take of Precipitated Carbonate of Zinc *twelve troyounces.* Expose it, in a shallow vessel, to a low-red heat until the water and carbonic acid are wholly expelled." *U. S.*

"Take of Carbonate of Zinc *six ounces.* Place the Carbonate of Zinc in a loosely covered Hessian crucible, and expose it to a dull red heat until a portion, taken from the centre of the contents of the crucible and cooled, no longer effervesces when dropped into diluted sulphuric acid. Let the crucible cool, and transfer the product to stoppered bottles." *Br.*

Both the Pharmacopœias prepare the oxide of zinc from the carbonate already formed. By referring to the article on Precipitated Carbonate of Zinc, it will be found that it is obtained in the U. S. and Br. processes from sulphate of zinc, by the decomposing influence of carbonate of soda. Other methods of obtaining the carbonate of zinc are by the mutual decomposition of the chloride and carbonate of soda and the sulphate and carbonate

* The following table, showing the percentage of anhydrous chloride of zinc in solutions of different densities, prepared by Mr. Charles Bullock, should have been given under the heading of Liquor Zinci Chloridi, but had not attracted our attention when revising that article for the present edition of the Dispensatory. The table is taken from the *Am. Journ. of Pharm.*, Sept. 1868, p. 397. The densities marked * were found by experiment, the others were calculated.

of ammonia; but the officinal plan is to be preferred. M. Lefort found it to furnish a carbonate which is washed with facility, and is convertible by calcination into a pure oxide, readily reduced to an impalpable and very light powder. (*Journ. de Pharm.*, 3e sér., xi. 329.) It is, besides, more economical. The carbonate of zinc, in whatever way obtained, is exposed to heat to drive off the carbonic acid and water, in order to obtain the oxide. According to Mohr, a full red heat is not necessary; a temperature between 536° and 572° being sufficient. It is probable that an unnecessarily high heat injures the oxide as a therapeutic agent.

Oxide of zinc may be obtained by the combustion of the metal; and in this way it was formerly prepared by the Dublin College. Zinc melts at 773°, and immediately becomes covered with a film of gray oxide. When the temperature reaches nearly to redness, it takes fire and burns with an intense white light, generating the oxide in the form of very light and white flocculi, resembling carded wool, which quickly fill the crucible, and are in part driven into the atmosphere by the current of air. The late Mr. G. D. Midgely, of London, several years ago, called attention to the production of oxide of zinc by combustion, and gave a description of the apparatus by which he was enabled to prepare from one to two hundred weight of the oxide at one operation. It consisted of a large muffle, heated to redness in a suitable furnace, and supplied with zinc from time to time as the combustion proceeded. The necessary draught of air was conveyed from the muffle by a tube, passing through the top of the furnace, and terminating in a vessel of water, in which the portion of oxide carried up by the current was retained. The resulting oxide was freed from particles of metallic zinc by being passed through a sieve.

Properties. The officinal oxide of zinc is an inodorous, tasteless, yellowish-white powder, insoluble in water and alcohol, and anhydrous. As obtained by combustion it is perfectly white. It dissolves readily in acids without effervescence; and in potassa and soda, but not in their carbonates. Being anhydrous, it is insoluble in ammonia; but the impure oxide found in the shops, being generally hydrated, is soluble in that alkali. At a low white heat it fuses, and at full whiteness sublimes. When prepared by combustion it was formerly called *pompholix*, *nihil album*, *lana philosophica*, and *flowers of zinc*. Its neutral solution in acids should give a white precipitate with ferrocyanide of potassium and hydrosulphuret of ammonia. If the precipitate with the former test is bluish-white, iron is indicated; if black with the latter, lead is shown. Prepared by the old officinal process, namely, by precipitating sulphate of zinc with ammonia, it contains the subsulphate, the acid of which may be detected by dissolving the oxide in nitric acid, and precipitating by nitrate of baryta. Sometimes it is obtained by precipitating chloride of zinc with ammonia, in which case the oxide contains subchloride, easily detected by nitrate of silver. If it contain white lead or chalk, it will not be entirely soluble in dilute sulphuric acid, but an insoluble sulphate of lead or of lime will be left. If iron be present, brownish red flocks of sesquioxide of iron will remain undissolved, when the muriatic solution of the oxide is treated with ammonia in excess. Oxide of zinc consists of one eq. of zinc 32·3, and one of oxygen $8 = 40·3$.

The powder sold in the shops as oxide of zinc is often very impure. Sometimes the carbonate is substituted for it, showing that the exposure to a red heat has been omitted. In this case the preparation will effervesce with acids. Most samples contain a large proportion of subsulphate, showing that the discarded but productive process of precipitating the sulphate of zinc solution by ammonia has been employed. Again, other samples contain subchloride. These spurious oxides are pointed out by Mr. Redwood, of London, as occurring in the English market, and, no doubt, are sold in the shops of the United States. (See *Pharm. Journ.*, Jan. 1855, p. 301.) Unfortunately, a white oxide is preferred by purchasers, though whiteness is generally a sign of impurity; the officinal oxide being yellowish-white.

Medical Properties and Uses. This oxide is tonic and antispasmodic. It

has been given in chorea, epilepsy, hooping-cough, spasm of the stomach dependent on dyspepsia, and other similar affections. Externally it is employed as an exsiccant to excoriated surfaces, sometimes by sprinkling it on the affected part, but generally in the form of ointment. (See *Unguentum Zinci Oxidi.*) The dose is from two to eight grains or more, repeated several times a day, and given in the form of pill.

Oxide of zinc, prepared by combustion, is extensively used in painting as a substitute for white lead, over which it has the advantage of not being discoloured by sulphuretted hydrogen. It has, moreover, the merit of not producing injurious effects on the workmen at all comparable to those caused by white lead. The oxide thus prepared, even though pure, should not be substituted for the officinal, as its state of aggregation is probably different.

ZINCI VALERIANAS. *U. S., Br. Valerianate of Zinc.*

"Take of Valerianate of Soda *two troyounces and a half;* Sulphate of Zinc *two troyounces* and *four hundred and twenty grains;* Distilled Water *a sufficient quantity.* Dissolve the salts separately, each in twenty fluidounces of Distilled Water, and, having heated the solutions to 212°, mix them, and set the mixture aside to crystallize. Decant the mother-water from the crystals, and put them upon a filter in a funnel to drain. Mix the mother-water and the drainings, evaporate at a heat not exceeding 200° to four fluidounces, and again set aside to crystallize. Add the crystals, thus obtained, to those in the funnel, wash the whole with a little Distilled Water, and, having removed them with the filter, spread them on bibulous paper, and dry them with a heat not exceeding 200°." *U. S.*

"Take of Sulphate of Zinc *five ounces and three-quarters* [avoirdupois]; Valerianate of Soda *five ounces* [avoird.]; Distilled Water *a sufficiency.* Dissolve the Sulphate of Zinc and the Valerianate of Soda, each in two pints [Imperial measure] of the Water; raise both solutions to near the boiling point, mix them, cool, and skim off the crystals which are produced. Evaporate the mother-liquor at a heat not exceeding 200°, till it is reduced to four [fluid] ounces; cool again, remove the crystals which have formed, and add them to those which have been already obtained. Drain the crystals on a paper filter, and wash them with a small quantity of cold Distilled Water, till the washings give but a very feeble precipitate with chloride of barium. Let them now be again drained, and dried on filtering paper at ordinary temperatures." *Br.*

These formulas are essentially the same as that of the late Dublin Pharmacopœia. In the formation of the salt a double decomposition takes place between the reacting salts, resulting in the production of valerianate of zinc and sulphate of soda. Upon mixing the hot solutions, crystals of the sparingly soluble valerianate of zinc form on the surface of the liquid; and, during the progress of its concentration to one-tenth, more of them are successively produced. These are then washed with cold distilled water to separate adhering sulphate of soda, drained on a filter, and dried.

Properties. This salt is in white, pearly scales, having a faint odour of valerianic acid, and a metallic, styptic taste. It dissolves in 160 parts of cold water, and in 60 of alcohol of 0·833. The solutions, which have an acrid reaction, become turbid on the application of heat, but clear again on cooling. The salt, as obtained by the officinal formulas, is anhydrous; but, when formed by exactly saturating carbonate of zinc, made into a paste with water, with valerianic acid, it contains twelve eqs. of water, and, when dried at 122°, perfectly resembles the anhydrous salt. (*G. C. Wittstein.*) Acetate of zinc, impregnated with oil of valerian, has been substituted for this salt; but at present, from the relative costliness of the oil, there is no inducement to this fraud. The butyrate of zinc has been sold in Paris for the valerianate, and is so like it as not to be distinguished by its physical properties. The two salts, however, may be discriminated by adding a concentrated solution of the acid of the suspected salt, obtained by distillation with sulphuric acid, to a concentrated solu-

tion of acetate of copper. If the acid is the butyric, its addition to the solution of the acetate disturbs the transparency of the latter, by the formation of a bluish-white precipitate; while, if the valerianic, no change is produced. (Larocque and Huraut, *Journ. de Pharm.*, 3e sér., ix. 430.)

Medical Properties. Valerianate of zinc was proposed as a remedy, on theoretical grounds, by Prince Louis-Lucien Bonaparte. Upon trial it was found to possess antispasmodic properties. By some of the Italian physicians it has been extolled as a remedy in neuralgic affections. Dr. Namias, of Venice, employed it with advantage in anomalous nervous affections, attended with palpitation of the heart, constriction of the throat, and pain in the head. Dr. Francis Devay, of Lyons, found it useful in epilepsy, and in the nervous affections which accompany chlorosis. The dose is one or two grains, repeated several times a day, and given in the form of pill. (See a paper on this valerianate by Prof. Procter, in the *Am. Journ. of Pharm.* for April, 1845.) B.

ZINCUM GRANULATUM. *Br. Granulated Zinc.*

"Take of Zinc of commerce *one pound.* Fuse it in an earthen crucible, heated to a sufficient but not excessive degree in a suitable fire, and pour the fluid metal in a thin stream into a vessel containing two gallons of cold water. Remove the Granulated Zinc from the water and dry it." *Br.*

TESTS.

In the Appendix of the British Pharmacopœia, two series of tests are given, one qualitative, the other quantitative, to which frequent reference is made throughout that work, and which, so far as they are not incidentally described in the Dispensatory, require a special notice in this place; as, otherwise, much that has been stated in regard to the British Preparations would be unintelligible.

1. *Qualitative Tests.*

Those here given are all in the state of solution, and are used for determining the character of particular substances, whether isolated or in composition; thus enabling us to ascertain the identity of medicines, their purity or impurity, and the character of the foreign ingredients which may be mixed with them accidentally, or with a view to adulteration.

Solution of Acetate of Copper. "Take of Subacetate of Copper of Commerce, in fine powder, *half an ounce* [avoirdupois]; Acetic Acid *one fluidounce* [Imperial measure]; Distilled Water *a sufficiency.* Dilute the Acid with half a fluidounce [Imp. meas.] of the Water; digest the Subacetate of Copper in the mixture at a temperature not exceeding 212° with repeated stirring, and continue the heat until a dry residue is obtained. Digest this in four [fluid]ounces of boiling Distilled Water, and by the addition of more of the Water make up the solution to five fluidounces. Filter it."

Solution of Acetate of Potassa. Dissolve half an avoirdupois ounce of Acetate of Potassa in five fluidounces of Distilled Water, and filter.

Solution of Acetate of Soda. Dissolve half an avoirdupois ounce of Acetate of Soda in five fluidounces of Distilled Water, and filter.

Solution of Albumen. Mix, by trituration in a mortar, the White of one Egg and four fluidounces of Distilled Water, and filter through clean tow previously moistened with Distilled Water. The solution should be prepared when wanted for use.

Solution of Ammonio-nitrate of Silver. "Take of Nitrate of Silver, in crystals, *a quarter of an ounce* [avoirdupois]; Solution of Ammonia *half a fluidounce*, or *a sufficiency;* Distilled Water *a sufficiency.* Dissolve the Nitrate in eight fluidounces of the

Water, and to the solution add the Ammonia until the precipitate first formed is nearly dissolved. Filter, and add Distilled Water, so that the bulk may be ten fluidounces."

SOLUTION OF AMMONIO-SULPHATE OF COPPER. "Take of Sulphate of Copper, in crystals, *half an ounce* [avoirdupois]; Solution of Ammonia, Distilled Water, each, *a sufficiency*. Dissolve the Sulphate in eight fluidounces of the Water, and to the solution add the Ammonia until the precipitate first formed is nearly dissolved. Filter, and then add Distilled Water, so that the bulk may be ten fluidounces."

SOLUTION OF AMMONIO-SULPHATE OF MAGNESIA. "Take of Sulphate of Magnesia *one ounce* [avoirdupois]; Chloride of Ammonium [Muriate of Ammonia] *half an ounce;* Solution [Water] of Ammonia *half a fluidounce;* Distilled Water *a sufficiency*. Dissolve the Sulphate and Chloride in eight fluidounces of the Water, and to the Solution add the Ammonia, and as much Distilled Water as will make up the bulk to ten fluidounces. Filter it."

SOLUTION OF BORACIC ACID. Dissolve *fifty grains* of Boracic Acid in one fluidounce of Rectified Spirit, and filter.

SOLUTION OF BROMINE. Upon *ten minims* of Bromine, in a bottle furnished with an accurately fitting glass stopper, pour *five fluidounces* of Distilled Water, and shake several times. Keep the solution excluded from the light.

SOLUTION OF CARBONATE OF AMMONIA. "Take of Carbonate of Ammonia, in small pieces, *half an ounce* [avoirdupois]; Distilled Water *ten fluidounces*. Dissolve and filter."

SOLUTION OF CHLORIDE OF AMMONIUM. *Solution of Hydrochlorate of Ammonia.* Dissolve *one avoirdupois ounce* of Chloride of Ammonium in *ten fluidounces* of Distilled Water, and filter.

SATURATED SOLUTION OF CHLORIDE OF CALCIUM. Dissolve *four ounces* [avoirdupois] of Chloride of Calcium in *five fluidounces* of Distilled Water, and filter.

SOLUTION OF CHLORIDE OF GOLD. "Take of fine Gold, reduced by a rolling machine to a thin lamina, *sixty grains;* Nitric Acid *one fluidounce and a half* [Imperial measure]; Hydrochloric Acid *seven fluidounces* [Imp. meas.]; Distilled Water *a sufficiency*. Place the Gold in a flask with the Nitric and six fluidounces of the Hydrochloric Acid, first mixed with four fluidounces of the Water, and digest until it is dissolved. Add to the solution the additional fluidounce of Hydrochloric Acid, evaporate at a heat not exceeding 212° until acid vapours cease to be given off, and dissolve the Chloride of Gold thus obtained in five fluidounces of Distilled Water. The solution should be kept in a stoppered bottle."

SOLUTION OF CHLORIDE OF TIN. "Take of Granulated Tin *one ounce* [avoirdupois]; Hydrochloric Acid *three fluidounces;* Distilled Water *a sufficiency*. Dilute the Acid in a flask with one fluidounce of the Water, and, having added the Tin, apply a moderate heat until gas ceases to be evolved. Add as much of the Water as will make up the bulk to five fluidounces, and transfer the solution, together with the undissolved tin, to a bottle with an accurately ground stopper."

SOLUTION OF GELATIN. "Take of Isinglass [Ichthyocolla], in shreds, *fifty grains;* Warm Distilled Water *five fluidounces*. Mix and digest for half an hour on a water-bath with repeated shaking, and filter through clean tow moistened with Distilled Water."

SOLUTION OF IODATE OF POTASH. "Take of Iodine, Chlorate of Potash, each, *fifty grains;* Nitric Acid *eight minims;* Distilled Water *ten fluidounces and a half*. Rub the Iodine and Chlorate of Potash together to a fine powder; place the mixture in a Florence flask, and, having poured upon it half a [fluid]ounce of the Water acidulated with the Nitric Acid, digest at a gentle heat until the colour of the iodine disappears. Boil for one minute, then transfer the contents of the flask to a capsule, and evaporate to perfect dryness at 212°. Finally dissolve the residue in the remaining ten [fluid]ounces of Distilled Water, filter the solution, and keep it in a stoppered bottle."

SOLUTION OF IODIDE OF POTASSIUM. Dissolve *one avoirdupois ounce* of Iodide of Potassium in *ten fluidounces* of Distilled Water, and filter.

SOLUTION OF OXALATE OF AMMONIA. "Take of Oxalate of Ammonia *half an ounce* [avoirdupois]; Warm Distilled Water *one pint* [Imperial measure]. Dissolve and filter."

SOLUTION OF PERCHLORIDE OF PLATINUM. "Take of thin Platinum foil *a quarter of an ounce* [avoirdupois]; Nitric Acid, Hydrochloric Acid, each, *a sufficiency;* Distilled Water *seven fluidounces*. Mix a fluidounce of the Nitric Acid with four fluidounces of the Hydrochloric Acid and two fluidounces of the Water; pour the mixture into a small flask containing the Platinum, and digest at a gentle heat, adding more of the Acids mixed in the same proportion, should this be necessary, until the metal is dissolved. Transfer the solution to a porcelain capsule, add to it a fluidrachm of Hydrochloric Acid,

and evaporate on a water-bath until acid vapours cease to be given off. Let the residue be dissolved in the remaining five [fluid]ounces of Distilled Water. Filter and preserve in a stoppered bottle."

Solution of Phosphate of Soda. Dissolve *one avoirdupois ounce* of crystallized Phosphate of Soda in *ten fluidounces* of Distilled Water, and filter.

Solution of Red Prussiate of Potash. *Solution of Ferridcyanide of Potassium* Dissolve *a quarter of an ounce* [avoirdupois] of crystallized Red Prussiate of Potash in five fluidounces of Distilled Water, and filter.

Solution of Sulphate of Indigo. "Take of Indigo, dry and in fine powder, *five grains;* Sulphuric Acid *ten fluidounces.* Mix the Indigo with a fluidrachm of the Acid in a small test tube, and apply the heat of a water-bath for an hour. Pour the blue liquid into the remainder of the Acid, agitate the mixture, and when the undissolved indigo has subsided, decant the clear liquid into a stoppered bottle."

Solution of Sulphate of Iron. Dissolve *ten grains* of Granulated Sulphate of Iron in *one fluidounce* of boiling Distilled Water, and filter. This solution should be prepared when wanted for use.

Solution of Sulphate of Lime. "Take of Plaster of Paris *a quarter of an ounce* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Rub the Plaster of Paris in a porcelain mortar for a few minutes with two [fluid]ounces of the Water, introduce the mixture thus obtained into a pint bottle [Imp. meas.] containing the rest of the Water, shake well several times, and allow the undissolved sulphate to subside. When this has occurred, filter."

Solution of Sulphide of Ammonium. "Take of Solution of Ammonia *five fluidounces.* Put three fluidounces of the Ammonia into a bottle, and conduct into this a stream of Sulphuretted Hydrogen so long as this gas continues to be absorbed; then add the remainder of the Ammonia, and transfer the solution to a green-glass bottle furnished with a well-ground stopper."

Solution of Tartaric Acid. Dissolve *one avoirdupois ounce* of crystallized Tartaric Acid in *eight fluidounces* of Distilled Water, add *two fluidounces* of Rectified Spirit, and keep the solution in a stoppered bottle. The spirit is added to preserve the solution.

Solution of Yellow Prussiate of Potash. *Solution of Ferrocyanide of Potassium.* Dissolve *a quarter of an ounce* [avoirdupois] of crystallized "Yellow Prussiate of Potash" in five fluidounces of Distilled Water, and filter.

2. *Quantitative Tests.*

The quantitative tests are intended to estimate the quantity of any particular substance in the mixture or compound submitted to examination. They are all liquid, being denominated in the British Pharmacopœia *Volumetric Solutions*, and have individually been frequently referred to, throughout the Dispensatory, when it was deemed proper to indicate a method of determining the strength of medicines or their preparations recognised in the British Pharmacopœia. The method of operating in volumetric analysis is simple. The quantities of the substance to be tested are expressed by grains, those of the test solution by grain-measures, that is, the volume of a grain of distilled water at 60°. A glass tube (*burette*) is to be provided, capable, when filled up to a point marked 0, of containing 1000 grains of distilled water at 60° F., and beneath this point graduated into 100 equal parts. Each part, therefore, corresponds to 10 grain-measures. Into this tube the volumetric solution is to be introduced of a certain strength, so that the quantity of the substance dissolved which may be consumed in the application of the test is at once known, by observing the number of grain-measures of the volumetric solution which have disappeared. This quantity, being known, measures the quantity of the substance acted on by the test, supposing the nature of the reactions to be understood, and the equivalents of the several substances well ascertained. For convenient measurement it will be necessary to have a cylindrical glass jar, capable of holding 10,000 grains of distilled water up to a point marked 0, and below this point graduated into 100 equal parts; and a flask which, when filled to a mark on the neck, contains precisely 10,000 grains of distilled water at 60°, or in other words, has a capacity of 10,000 grain-measures. The volumetric solutions, before being used, should

be well shaken, in order that they may be uniform throughout. They should be kept in stoppered bottles. All the measurements should be made at 60° F.

Volumetric Solution of Bichromate of Potassa. Formula of the salt $KO,2CrO_3$ =147·5. "Take of Bichromate of Potash 147·5 grains; Distilled Water a sufficiency. Put the Bichromate into the 10,000 grain flask, and, having half filled the flask with the Water, allow the salt to dissolve; then dilute the solution with more Water, until it has the exact bulk of 10,000 grain-measures." (*Br.*) "The quantity of this solution which fills the volumetric tube to 0 (1000 grain-measures), contains one-tenth of an equivalent, in grains (14·75 grains), of the Bichromate of Potash, and, when added to a solution of a protosalt of iron acidulated with hydrochloric acid, is capable of converting one-tenth of six eqs. of iron (16·8 grains) from the state of a protosalt to that of a persalt [sesquisalt]. In practising this volumetric process, it is known that the whole of the protosalt has been converted into a persalt, when a minute drop of the solution, placed in contact with a drop of the solution of ferridcyanide of potassium, on a white plate, ceases to strike with it a blue colour." *Br.* 1864.

It is obvious, therefore, that, by means of this test, it is possible to estimate the quantity of protoxide, protochloride, protiodide, or protobromide of iron in any mixture or compound in which it may exist. The rationale, in reference to the protoxide of iron, is that two eqs. of the bichromate containing two eqs. of chromic acid ($2CrO_3$), and of course six eqs. of oxygen, give up three eqs. of oxygen, whereby the acid becomes sesquioxide of chrome (Cr_2O_3), to six eqs. of the protoxide of iron ($6FeO$), converting them into three eqs. of the sesquioxide ($3Fe_2O_3$); and, in reference to haloid salts, it is only necessary that each of them should be preliminarily converted, through the instrumentality of the water present, into the protoxide and the acid corresponding with its other element, in order that the same reaction should be exerted upon it as on the protoxide.

Volumetric Solution of Hyposulphite of Soda. Formula of the crystallized salt $NaO,S_2O_2+5HO=124$. "Take of Hyposulphite of Soda, in crystals, 260 *grains;* Distilled Water *a sufficiency.* Dissolve the Hyposulphite in 10,000 grain-measures of the Water. Fill a burette with this solution and drop it cautiously into 1000 grain-measures of the volumetric solution of Iodine until the brown colour is just discharged. Note the number of grain-measures (n) required to produce this effect; then put 8000 grain-measures of the same solution into a graduated jar, and augment this quantity by the addition of Distilled Water until it amounts to $\frac{8000\times1000}{N}$ grain-measures. If, for example, $n=950$, the 8000 grain-measures of solution should be diluted to the bulk of $\frac{8000\times1000}{950}=8421$ grain-measures. Of this solution 1000 grain-measures contain 24·8 grains of the hyposulphite ($\frac{1}{10}$th of $2(NaO,S_2O_2+5HO)$, in grains), and, therefore, correspond to 12·7 grains of iodine ($\frac{1}{10}$th of an equivalent)." *Br.*

"This solution is used for estimating free iodine, an object which it accomplishes by forming with the iodine, iodide of sodium and tetrathionate of soda. One thousand grain-measures of it include one-tenth of two eqs. of the hyposulphite in grains, and therefore correspond to 12·7 grains of free iodine." *Br.* 1864.

Tetrathionic acid consists of four eqs. of sulphur and five of oxygen; and tetrathionate of soda would be represented by the formula NaO,S_4O_5. When the hyposulphite (*dithionate*) of soda (NaO,S_2O_2) reacts with iodine, two eqs. of the salt are called into action, and, by the substitution of one eq. of iodine for one eq. of oxygen of the soda, become one eq. of iodide of sodium, one of soda, and one of tetrathionate of soda; as represented by the following equation, $I+2(NaO,S_2O_2)=NaI+NaO,S_4O_5$. Two eqs. of the test salt are therefore capable of neutralizing and rendering invisible one eq. of iodine; and, as the eq. of the salt is 124 and that of iodine 127, it follows that 248 grains of it should neutralize 127 grains of iodine, or every grain of the former consumed would indicate the neutralization of ·512 grain of the latter as nearly as may be.

Volumetric Solution of Iodine. Formula I=127. "Take of Iodine 127 *grains;* Iodide of Potassium 180 *grains;* Distilled Water *a sufficiency.* Put the Iodide of Potassium and Iodine into the 10,000 grain flask, fill the flask to about two-thirds of its bulk with the Distilled Water, gently agitate until solution is complete, and then dilute the solution with more of the Water, until it has the exact volume of 10,000 grain-measures. Of this solution 1000 grain-measures contain $\frac{1}{10}$th of an eq. in grains (12·7 grains) of iodine, and therefore correspond to 1·7 grains of sulphuretted hydrogen, 3·2 grains of sulphurous, and 4·95 grains of arsenious acid."

This solution may be employed for determining the amount of sulphuretted hydrogen or of a metallic sulphuret in a fluid, but is chiefly used for the estimation of sulphurous and arsenious acids. It is dropped from the volumetric tube into the liquid to be tested until free iodine begins to appear in the solution.

Volumetric Solution of Nitrate of Silver. Formula of the salt $AgO,NO_5=170$. "Take of Nitrate of Silver 170 *grains;* Distilled Water *a sufficiency.* Put the Nitrate into the 10,000 grain flask, and having half filled the flask with the Water, allow the

salt to dissolve; then dilute the solution with more of the Water until it has the exact bulk of 10,000 grain-measures. The solution should be kept in an opaque stoppered bottle. Of this solution 1000 grain-measures contain $\frac{1}{10}$th of an eq. in grains of nitrate of silver, or 17·0 grains." Upon dropping it into dilute hydrocyanic acid rendered alkaline by soda, the precipitate first formed is upon agitation redissolved, and continues to be so until the whole of the cyanogen of the acid has united with the sodium and silver, forming the double cyanide of sodium and silver. In such experiments 1000 grain-measures of the solution correspond to 5·4 grains of absolute hydrocyanic acid.

Volumetric Solution of Oxalic Acid. Formula of crystallized oxalic acid $2HO, C_4O_6 + 4HO = 126$. "Take of Purified Oxalic acid, in crystals, quite dry, but not effloresced, 630 *grains;* Distilled Water *a sufficiency.* Put the Oxalic Acid into the 10,000 grain flask, fill the flask to about two-thirds of its bulk with the Water, allow the acid to dissolve, and then dilute the solution with more of the Water until it has the exact volume of 10,000 grain-measures. Of this solution 1000 grain-measures contain half an eq. in grains (63) of oxalic acid, and are therefore capable of neutralizing one eq. in grains of an alkali or alkaline carbonate."

Volumetric Solution of Soda. Formula of hydrate of soda $NaO,HO = 40$. "Take of Solution of Soda, Distilled Water, each, *a sufficiency.* Fill a burette with the Solution of Soda, and cautiously drop this into 63 grains of Purified Oxalic Acid dissolved in about two ounces of the Water, until the acid is exactly neutralized as indicated by litmus. Note the number of grain-measures (n) of the solution used, and having then introduced 9000 grain-measures of the Solution of Soda into a graduated jar, augment this quantity by the addition of Water, until it becomes $\frac{9000 \times 1000}{N}$ grain-measures. If, for example, $n = 930$, the 9000 grain-measures should be augmented to $\frac{9000 \times 1000}{930} = 9677$ grain-measures. Of this solution 1000 grain-measures contain one eq. in grains (40 grains) of hydrate of soda, and will, therefore, neutralize one eq. in grains of any monobasic acid." *Br.*

PART III.

DRUGS AND MEDICINES NOT OFFICINAL.*

In the progress of the medical art, numerous remedies have at different times risen into notice and employment, which, by the revolutions of opinion incident to our science, or by the discovery of more efficient substitutes, have so far fallen into disrepute as to have been discarded from general practice, and no longer to hold a place in the officinal catalogues. Of these, however, some are still occasionally employed by practitioners and referred to by writers, and many retain a popularity as domestic remedies, or among empirics, which they have lost with the medical profession generally. The attention of physicians must, therefore, frequently be called to them in the course of practice; and it is highly desirable to possess some knowledge of their properties and effects, in order to be enabled to judge of their agency in any particular case, and at the same time to avoid the suspicion of incompetence which might attach to the exhibition of entire ignorance in relation to them. The remark is true also of other substances, which, though at no time ranked among regular medicines, are yet habitually employed in families, and the influence of which, either remediate or otherwise, must often enter into our estimate of the causes which produce or modify disease. New medicines, moreover, are frequently brought forward, which, without having obtained the sanction of the medical authorities, are occasionally prescribed, and therefore merit notice. To supply, to a certain extent, the requisite means of information in regard to these extra-officinal remedies, is the object of the following brief notices, among which are also included accounts of substances not employed as medicines, but usually kept in the drug stores for various purposes connected with the arts, or with domestic convenience. In a work intended for the use as well of the apothecary and druggist as of the physician and medical student, the introduction of such accounts is obviously proper, if kept in due subordination to the more important object of teaching the properties of medicines, and the modes of preparing them. The authors regret that the limits, which practical convenience appears to require in a Dispensatory, do not admit of a more complete enumeration of the various drugs and medicines of the kind above alluded to, or of ampler details in relation to those actually treated of, than will be found in the following pages. They have endeavoured, however, in the selection of objects, to choose those which are likely most frequently to engage the attention of the medical and pharmaceutical professions, and, in the extent of the descriptions, to consult as far as possible the relative importance of facts, of which they could not detail the whole. In relation to the nomenclature employed, it may be proper to observe that all those vegetable remedies, which, not being generally kept in the shops, have no current commercial name, are described under the scientific title of the plant producing them; while other substances are designated by the names which ordinary usage has assigned them. W.

* By the term officinal medicines, here as well as elsewhere in this work, are meant such as are embraced in the United States and British Pharmacopœias.

ACETATE OF ALUMINA. This salt may be obtained by the direct combination of hydrated alumina with acetic acid, or by reaction between sulphate of alumina and acetate of lead. According to Crum, when pure tersulphate of alumina and neutral acetate of lead are mixed, the resulting salt is apparently biacetate of alumina, which remains in solution with one eq. of pure acetic acid, as there is no teracetate of alumina. The solution, filtered to separate the sulphate of lead and evaporated, yields a gummy mass, which reddens litmus, and has an astringent taste. But if means are used to evaporate the solution quickly, at a low temperature, the salt is obtained dry and in a perfectly soluble state ($Al_2O_3.2C_4H_3O_3+4HO$). (*Gmelin's Handbook*, viii. 303.) It is deliquescent. Acetate of alumina is valuable only as a disinfectant, operating in this way like the sulphate of alumina, and employed in the same manner. (See *Aluminæ Sulphas* in *Part* II., page 1010.) W.

ACETATE OF COPPER. *Cupri Acetas. Crystals of Venus.* This salt is prepared by dissolving verdigris, with the assistance of heat, in vinegar or dilute acetic acid. The solution, after having been sufficiently concentrated, is transferred to suitable vessels, where it crystallizes on cooling. Another method of preparing it is recommended by M. Jonas, who dissolves sulphate of copper in water of ammonia to complete neutralization, and then, having added an excess of concentrated vinegar, boils all together. Fine crystals of neutral acetate of copper soon make their appearance on the surface of the liquid. The change is so rapid that the liquor in a little while appears to consist of two parts, of which the upper is translucent, and of a greenish colour, and the lower is formed of fine crystals of acetate of copper. From 1000 parts of the sulphate, 750 parts of the acetate are thus obtained. The crystals procured in this manner differ from those of commerce in having a brighter green colour, and a more ready solubility in water. (*Journ. de Pharm.*, 4e sér., ii. 314.) Acetate of copper is a slightly efflorescent salt, crystallizing in rhomboidal prisms, and having a rich deep-green colour and strong styptic taste. It dissolves in water without residue, a character which serves to distinguish it from verdigris. It consists of one eq. of acetic acid, one of protoxide of copper, and one of water. Its popular name of *distilled verdigris* is inappropriate; as no distillation is practised in its preparation. This salt is used for colouring maps. It was formerly the chief source of acetic acid. It has been used in the form of tincture by Dr. Rademacher in fevers; but with no very definite object. B.

ACETATE OF MAGNESIA. *Magnesiæ Acetas.* This salt has been proposed as a purgative by M. Renault, of Paris. It is deliquescent, and cannot be crystallized without difficulty. (*Carl von Hauer.*) It has the merit of extreme solubility both in water and alcohol. Though without much taste, it is inferior in that respect to citrate of magnesia, for which it is proposed as a substitute. It is prepared for therapeutic use by saturating 120 parts of carbonate of magnesia with acetic acid, and evaporating the resulting liquid, after filtration, to 300 parts. The product is a syrupy acetate of magnesia, which is to be mixed with three times its weight of syrup of oranges, to form the preparation of M. Renault. Of this about four ounces is the dose. An objection to the liquid acetate is, that, owing to its attraction for moisture, it cannot be preserved of uniform strength for mixing with the syrup of oranges. (*Journ. de Pharm.*, 3e sér., xiii. 260.) B.

ACETIC ETHER. *Æther Aceticus.* This ether may be formed by several processes, the chief of which are the following.—1. Mix 100 parts of alcohol (sp. gr. 0·83) with 63 parts of concentrated acetic acid, and 17 parts of strong sulphuric acid, and distil 125 parts into a receiver, kept cold with wet cloths. 2. Distil to dryness a mixture of three parts of acetate of potassa, three of alcohol, and two of sulphuric acid, mix the distilled product with one-fifth of sulphuric acid, and distil a second time an amount of ether equal to the alcohol employed. 3. Distil two parts of effloresced acetate of lead with one part of alcohol, and a little more than one part of sulphuric acid. In the last two processes, the acetic acid is set free by the action of the sulphuric acid on the acetate employed. Acetic ether is colourless, of a grateful odour, and a peculiar, agreeable taste. Its sp. gr. is 0·866, and its boiling point 160°. It undergoes no change by keeping. By contact with flame it burns readily, diffusing an acid odour. It dissolves in 7·5 parts of water, and unites in all proportions with alcohol. It consists of one eq. of acetic acid 51, and one of oxide of ethyl (ether) 37=88 ($C_4H_5O,C_4H_3O_3$).

Acetic ether is occasionally used in medicine as a stimulant and antispasmodic. The dose is from fifteen to thirty drops, sufficiently diluted with water. It is sometimes employed externally, by friction, as a resolvent, and for rheumatic pains. B.

ACTÆA SPICATA. *Baneberry. Herb Christopher.* This is a perennial, herbaceous, European plant, growing in the woods of mountainous regions, and attaining a height of two feet or more. The root is of a dark-brown colour, and bears some resemblance to that of Helleborus niger, for which it is said to be occasionally substituted. Its odour, in the recent state, is sweetish and rather nauseous, but is in great measure dissipated by drying. The taste is bitterish and somewhat acrid. In its operation on the system, the root is purgative and sometimes emetic, and is capable, in overdoses, of producing dangerous effects. It is unknown in this country. We have, however, a native species of Actæa, *A. Americana* of Pursh, of which there are two varieties—*alba* and *rubra*—distinguished by the colour of their berries, which in the former are white, and in the latter red. They are sometimes called *white* and *red cohosh*, a name derived from the language of the aborigines. By some

botanists they are treated of as distinct species, under the names of *Actæa alba* and *Actæa rubra*. They grow in the rich deep mould of rocky woods, from Canada to Virginia. They are said to have been much esteemed by the Indians. Their medical properties are probably similar to those of *A. spicata*. The name *baneberry*, given to different species of Actæa, was derived from the reputed poisonous properties of their berries. Mr. Frederick Stearns, in his account of the medical plants of Michigan, speaks of the rhizoma of Actæa alba as being violently purgative. (*Proceed. of the Am. Pharm. Assoc.*, 1858, p. 240.) W.

ADANSONIA DIGITATA. *Baobab.* A tree of enormous magnitude, belonging to the Linnæan class and order Monadelphia Polyandria, and to the natural family Sterculiaceæ (*Lindley*). It is a native of Africa, extending quite through that continent from Senegal to Abyssinia, and has been introduced into the West Indies. The leaves and bark of this tree abound in mucilage, and have little smell or taste; yet extraordinary virtues have been ascribed to them. Adanson found the leaves very useful as a preventive of fevers, and they are employed habitually by the native Africans with a view to their diaphoretic property. Dr. Duchassaing, of Guadaloupe, has published a statement of his experience with the bark, in the miasmatic diseases of the West Indies. Out of 93 cases, chiefly of intermittent fever, he failed only in three. M. Pierre has subsequently employed the remedy with success in intermittent fever at Burgogne, in France. (*Arch. Gén.*, 3e sér., xxiii. 535.) The bark has the advantage over cinchona of being almost without taste, and quite acceptable to the stomach. It produces no other observable physiological effect than increase of appetite, increased perspiration, and perhaps diminished frequency of pulse. An ounce may be boiled in a pint and a half of water to a pint, and the whole taken in a day. (*Journ. de Pharm.*, 3e sér., xiii. 412 and 421.) The fruit, which contains a subacid not disagreeable pulp, is used by the Africans in dysentery and other bowel complaints. W.

ADIANTUM PEDATUM. *Maidenhair.* An indigenous fern, the leaves of which are bitterish and aromatic, and have been supposed to be useful in chronic catarrhs and other pectoral affections. A European species, known by the same vulgar name, is the *A. Capillus Veneris*, which has similar properties, though feebler, and has been much used as a pectoral, on the continent of Europe, from very early times. It is given in the form of infusion, sweetened with sugar or honey; and a syrup prepared from it is popular in France, under the name of *sirop de capillaire*. The name of maidenhair has also been given to *Asplenium Trichomanes*, the leaves of which have a mucilaginous, sweetish, somewhat astringent taste, and have been used for the same purposes with those of the plants above mentioned. Another species of Asplenium, *A. Adiantum nigrum*, has been substituted for the genuine maidenhair; but neither of them has the aromatic flavour of that fern. W.

ÆSCULUS HIPPOCASTANUM. *Horsechestnut.* The horsechestnut is a native of Asia, and was introduced about the middle of the sixteenth century into Europe, where, as well as in this country, it is now extensively cultivated as an ornamental tree. Quercitrin has been found by Rochleder in very small proportion in the leaves. (*Journ. de Pharm.*, Mai, 1859, p. 393.) *Fraxin*, a peculiar principle of the bark of Fraxinus excelsior, has been detected also, by Mr. Stokes, in the bark of the horsechestnut; and Rochleder has discovered in the capsules of the fruit a peculiar acid, which he names *capsulæscic acid.* (*Ibid.*, Août, 1860, p. 151.) The fruit and bark have been used in medicine. The *fruit* abounds in starch, but has a rough, disagreeable, bitter taste, which renders it unfit for food, though it is said to be eaten with avidity by horses, oxen, hogs, and sheep. It may be deprived, in great measure, of the bitter principle by maceration in an alkaline solution. The starch may be readily obtained in a state of purity, and is said to excel as an article of diet that procured from the potato. (*Dict. de Mat. Méd.*) Considerable quantities have recently been prepared in France for use; the nut being reduced to a pulp, washed, and treated like the potato. (*Am. Journ. of Sci. and Arts*, Sept. 1856, p. 264.) The bitter principle is denominated *æsculin*, and, according to Rochleder, may be obtained by precipitating with acetate of lead a decoction of the rind, filtering, treating the filtered liquor with sulphuretted hydrogen, again filtering, evaporating to the consistence of syrup, and setting the residue aside in a cool place. In a few days, the liquid is converted into a mass of crystals, which are to be expressed, and purified by repeated crystallization from alcohol, and afterwards from boiling water. If now washed on a filter with cold water till they have lost one-third of their weight, they are rendered as pure as it is possible to obtain them. Esculin is in shining white, prismatic crystals, inodorous, bitter, but slightly soluble in cold water, more soluble in boiling water, and very readily so in boiling alcohol, and in alkaline solutions. Its solution is precipitated by subacetate of lead. It consists of carbon, hydrogen, and oxygen; and its formula, according to Rochleder, is $C_{60}H_{33}O_{37}$. (*Journ. de Pharm.*, 3e sér., xxiii. 474, and xxiv. 292.) When treated with dilute sulphuric acid, it is converted into grape sugar, and a peculiar substance called *esculetin.* (*Chem. Gaz.*, Jan. 15, 1857, p. 27.) The powdered kernel of the fruit, snuffed up the nostrils, produces sneezing, and has been used with advantage as a sternutatory in complaints of the head and eyes. A fixed oil extracted from the kernels by percolation with ether, and obtained separate by evaporating the ether, has recently been used in France as a topical remedy in gout and rheumatism, being applied by means of a hair brush to the part affected, which is then covered with waxed paper, cotton wadding, or flannel. The kernels yield only one-tenth of 1 per cent. of the oil. (See *Am. Journ. of Pharm.*, May, 1859, p. 231.)

The *bark* of the horsechestnut has attracted much attention on the continent of Europe, as a substitute for cinchona. That of the branches from three to five years old is considered best. It should be collected in the spring. It has little odour, but an astringent and bitter, though not very disagreeable taste. It contains, among other ingredients, a bitter principle and tannin, and imparts its virtues to boiling water. The tannin is found in all parts of the tree, including the *leaves* as well as the bark and fruit. According to Rochleder, when pure, it is white and soluble in water, alcohol, and ether; becomes red by the absorption of oxygen; colours *green* the persalts of iron, but *violet* on the addition of a little alkali; precipitates gelatine but not tartar emetic; in concentrated solution, is precipitated, at least partially, by sulphuric, muriatic, and metaphosphoric acids, while acetic acid is opposed to this result; and forms also, with the sulphites of potassa and soda and the hydrosulphate of ammonia, precipitates which are dissolved by dilute acetic acid. (*Journ. de Pharm.*, Janv. 1868, p. 72.) By many physicians it has been found very efficacious in the treatment of intermittent fever; but it has entirely failed in the hands of many others, and certainly cannot be considered comparable to the Peruvian bark in its power over that complaint. It is at present seldom used, and never in this country. It has been given in substance, decoction, and extract. From half an ounce to an ounce of the powder may be given in the course of twenty-four hours. The decoction is prepared and administered in the same manner as that of Peruvian bark. Esculin was given, with complete success by M. Monvenoux, in four cases of periodical neuralgia, in one of which quinia had failed. He gave 30 grains, at two doses, mixed with sweetened water. (*Ann. de Thérap.*, 1859, p. 160.) At a later period, the same principle has been found useful in neuralgia of the uterus, stomach, and bowels, and in periodical fevers, by M. Vicaire, in doses varying from seven to thirty grains. (*Ibid.*, 1860, p. 198.) W.

AGARIC. *Touchwood. Spunk. Tinder.* This is the product of different species of a genus of mushrooms denominated *Boletus*. Several species are used as food, several are poisonous, and two at least have been ranked among officinal medicines in Europe. *Boletus laricis*, which grows upon the larch of the old world, is the *white agaric* or *purging agaric* of medical writers. It is of various sizes, from that of the fist to that of a child's head, or even larger, hard and spongy, externally brownish or reddish; but, as found in commerce, it is deprived of its exterior coat, and consists of a light, white, spongy, somewhat farinaceous, friable mass, which, though capable of being rubbed into powder upon a sieve, is not easily pulverized in the ordinary mode, as it flattens under the pestle. It has a sweetish very bitter taste, and consists, according to Braconnot, of 72 parts of resinous matter, 2 of bitter extractive, and 26 of *fungin*, a nutritious animalized principle, constituting the base of the fleshy substance of mushrooms. It contains also benzoic acid and various saline compounds. In the dose of four or six grains, it is said to act powerfully as a cathartic; but Lieutaud asserts that it may be given in the quantity of thirty grains or a drachm without sensibly purging. M. Andral has found it useful in checking the night-sweats of phthisis. He uses it in doses of eight grains, and gradually increases to a drachm during the day, without any observable inconvenience to the digestive functions. In this country it is scarcely employed, though we have met with it in the shops. That which is most esteemed is said to be brought from Siberia; but it is probably produced wherever the European larch grows. Dr. Wm. M. McPheeters has published, in the *St. Louis Med. and Surg. Journ.* (x. 421), an account of several cases, in which he tried a specimen of Boletus laricis, brought from the Rocky Mountains, in almost all of which it proved decidedly cathartic. The dose was 25 grains, which it was sometimes necessary to repeat. A tincture of the agaric of the Canadian larch has been used successfully in rheumatism by Dr. J. A. Grant. (*British-Am. Journ.*, April, 1862.)

Boletus igniarius, or *agaric of the oak*, like the species just described, is compared in shape to the horse's hoof. Its diameter is from six to ten inches. It is soft like velvet when young, but afterwards becomes hard and ligneous. It usually rests immediately upon the bark of the tree, without any supporting footstalk. On the upper surface it is smooth, but marked with circular ridges of different colours, more or less brown or blackish; on the under, it is whitish or yellowish, and full of small pores; internally it is fibrous, tough, and of a tawny-brown colour. It is composed of short tubular fibres compactly arranged in layers, one of which is added every year. The best is that which grows on the oak, and the season for collecting it is August or September. It has neither taste nor smell. Among its constituents, according to Bouillon-Lagrange, are extractive, resin in very small proportion, azotized matter also in small quantity, chloride of potassium, and sulphate of lime; and in its ashes are found iron, and phosphate of lime and magnesia. It is prepared for use by removing the exterior rind or bark, cutting the inner part into thin slices, and beating these with a hammer until they become soft, pliable, and easily torn by the fingers. In this state it was formerly much used by surgeons for arresting hemorrhage, being applied immediately, with pressure, to the bleeding vessel. It probably acts mechanically, like any other soft porous substance, by absorbing the blood and causing it to coagulate, and is not relied on in severe cases. In the obstinate hemorrhage which occasionally takes place from leech bites, especially those of the European leech, it may be used advantageously, though perhaps not more so than well-prepared lint. It has been sometimes applied to the purposes of moxa.

When prepared agaric is steeped in a solution of nitre, and afterwards dried, it becomes very readily inflammable, and is employed as tinder. Some recommend the substitution of chlorate of potassa for nitre. The preparation is usually known by the name of *spunk*, and is brought to us from Europe. Spunk or tinder, the *amadou* of the French, is in flat pieces, of a consistence somewhat like that of very soft, rotten buckskin leather, of a brownish-yellow colour, capable of absorbing liquids, and inflammable by the slightest spark. It is said to be prepared also from various other species of Boletus, as *B. ungulatus*, *B. fomentarius*, *B. ribis*, &c. W.

AGAVE AMERICANA. *American Agave. American Aloe. Maguey.* An evergreen succulent plant, indigenous in Florida, Mexico, and other parts of tropical America, and largely cultivated, chiefly for hedges, in the South of Europe, especially in Spain. This and other species of Agave bear a considerable resemblance, in appearance, to the plants of the genus Aloe, with which they are sometimes confounded. From the root and leaves of the American agave, when cut, a saccharine juice flows out, which may be converted by evaporation into syrup and even sugar, and by fermentation into a vinous liquor. According to M. Lenoble, this juice when fresh has an herbaceous somewhat nauseous odour and acrid taste, and reddens litmus paper. It is said to be laxative, diuretic, and emmenagogue. Dr. G. Perin, of the U. S. army, has found the juice an admirable remedy in scurvy, being more prompt and efficacious even than lime-juice. He gave two fluidounces three times a day. (*N. Y. Journ. of Med.*, N. S., vii. 181.) According to M. Bazire, however, it is not the *A. Americana* which produces the sweet juice from which the intoxicating *pulqué* of the Mexicans is obtained, but another species, bearing considerable resemblance to the Americana. The latter plant, he informs us, yields a very bitter, viscid, and astringent juice, while it is from the Agave *pulqué* that the sweet fermentable juice is procured. (*Journ. de Pharm.*, 4e sér., iv. 103–4.) The expressed juice, evaporated to the consistence of a soft extract, forms a lather with water, and is employed as a substitute for soap. The fibres of the old leaves, separated by bruising and maceration in water, are used for forming thread. In the vicinity of Cordova, in Spain, the author had an opportunity of seeing the preparation of those fibres by the peasantry. Hung up to dry, they appeared at a little distance like bundles of silk. M. Lenoble found in the leaves an acrid volatile oil, a gum-resinous principle, lignin, salts of potassa and lime, and silica; and thinks that a vinegar or ointment of the leaves might be advantageously used as an epispastic. (*Journ. de Pharm. et de Chim.*, xv. 350.) It is said that a gum exudes and hardens on the leaves of the Maguey, which has been compared to gum arabic, but in fact differs from it in containing a much larger proportion of lime, and in being only partially soluble in water; the soluble portions resembling pure gum, but the larger insoluble portions having all the characteristics of bassorin. (*Ibid.*, 4e sér., iv. 104.) *Agave Virginica*, which grows in our Southern States, and is known in South Carolina by the name of *rattlesnake's master*, has a very bitter root, which is used, in the form of tincture, in flatulent colic, and as a counter-poison in the bites of serpents. (Robert King Reid, *Inaug. Thes.*, A. D. 1849.) W.

AGRIMONIA EUPATORIA. *Common Agrimony.* This species of agrimony is a perennial herb, inhabiting Asia, Europe, and North America, and, in this country, found in fields and on the borders of woods, and flowering during the summer months. Its stem, which rises from one to three feet in height, is hairy, furnished with interruptedly pinnate leaves, and terminated by a long simple spike of yellow flowers. Both the herb and root have been employed. The former has a weak but agreeable aromatic odour, and a rough, bitterish, somewhat aromatic taste. The fragrance is strongest in the flowers. The root has similar properties; but its taste is more bitter and astringent. A volatile oil may be obtained from the plant by distillation. Agrimony is a mild corroborant and astringent. The herb has been employed in relaxed conditions of disease, as in passive hemorrhages, and chronic affections of the mucous membranes. It has been recommended, also, as a deobstruent in jaundice and visceral obstructions, and as an alterative in diseases of the skin. In Europe it is popularly used, in the form of a gargle, in affections of the throat. The Indians of North America and the Canadians are reported to have employed the root with advantage in fevers. The plant may be given in substance, infusion, or decoction. The dose of the powder is a drachm or more. W.

AILANTHUS GLANDULOSA. This tree is well known in the United States, where it has within a few years been extensively cultivated as a shade tree, for which purpose it would be admirably adapted by its rapid growth and abundant foliage, as well as by its exemption from the attacks of insects, were it not for the offensive odour emitted by it in its flowering period. The tree belongs to Polygamia Monœcia in the Linnæan system, and to the natural order of Rutaceæ, *Juss.*, Xanthoxylaceæ, *Lindley*. In its general aspect and the character of its foliage, it appears like a gigantic sumach, and it was at one time considered as a Rhus. The name of *Japan varnish* (*vernis du Japon*), by which it is known in France, arose from its having been mistaken for the true Japan varnish tree, which is a species of Sumach. Attention has recently been called to this tree in France by M. Hétet, Professor in the Marine Medical School at Toulon, who has found it to possess properties which promise to render it of great use in medicine, especially as a vermifuge. Before it had engaged his notice as a medical plant, it had begun to assume considerable importance in an economical point of view; its leaves having been found to be suitable food for a species of silk worm,

Bombyx cinthia, imported from China. The bark is the part in which its anthelmintic virtues have been shown to reside. This, in powder, is of a greenish-yellow colour, a strong, narcotic, nauseating odour, in its recent state, and of a strongly bitter taste. When chewed, besides the bitterness, it appears, through its influence on the gustatory nerves, to produce in a few moments a general uneasiness, a sense of increasing weakness, dazzling, cold sweats, with shivering and nauseous sensations, which are very remarkable, but seem to be well attested. The inference from these effects is that it has probably a powerful depressing agency on the nervous system, similar to that of tobacco. Examined chemically, the bark has been found to contain lignin, chlorophyll, a yellow colouring principle, a gelatinous substance (pectin), a bitter substance, an odorous resin, traces of a volatile oil, an azotized fatty matter, and several salts. An *oleoresin* is obtained from the bark by the action of alcohol, which has the consistence of tar, a very dark greenish-brown colour, and in a high degree the smell and taste of the bark. M. Illétet experimented upon dogs with the powdered bark, powdered leaves, and various preparations of the bark. As a general result, they were found to produce a purgative effect, with copious stools and the discharge of worms. The resin purged, but rarely acted as an anthelmintic. The depressing effects on the nervous system in man were found to depend on the volatile oil, as the resin alone had no such influence. The oil is so powerful that persons exposed to the vapours, in preparing the extract, are liable to be seized with vertigo, cold sweats, and vomiting. The powdered bark has been given in several cases of tape-worm in the human subject, and proved remarkably successful in its expulsion, at the same time operating on the bowels. The oleoresin produced the same effect in a somewhat smaller dose, and has the advantage that it keeps better than the bark, which loses its powers with age. A fact worthy of remark is that neither the bark nor its preparation, taken internally, produce vomiting in man; while this effect is determined by the inhalation of its vapours, when it is boiled. The cathartic operation is not violent. The dose of the powder which was found sufficient for the expulsion of the tape-worm was from seven or eight to thirty grains. (*Journ. de Pharm.*, Mars, 1859, p. 163.) W.

AJUGA CHAMÆPITYS. *Ground Pine. Chamæpitys.* A low, creeping, annual, labiate plant, a native of Europe, and found also in some parts of the United States. The leaves, which bear some resemblance to those of the pine in shape, have a strong, peculiar, resinous, not disagreeable odour, and a bitter, balsamic taste. They yield by distillation with water a small proportion of volatile oil, resembling that of turpentine. They are said to be stimulant, diuretic, and aperient; and have been given in rheumatism, gout, palsy, and amenorrhœa. The dose of the leaves in powder is one or two drachms; but their infusion in wine is considered the best preparation.

Ajuga reptans or *common bugle*, and *A. pyramidalis*, perennial plants of Europe, have also been used in medicine. They are nearly inodorous, but have a somewhat astringent, bitterish, and saline taste. Their virtues are probably those of a mild astringent and tonic. They have been recommended in pulmonary consumption, hæmoptysis and other hemorrhages, and in hepatic obstructions, and have enjoyed considerable reputation as vulneraries; but they are at present nearly obsolete. W.

AKAZGA. *Boundou.* These are the native names of an ordeal poison, used in a district on the West Coast of Africa, extending far into the interior, north and south of the equator, from the use of which in their trials thousands of persons are said to perish annually. It is referred to in the works of Du Chaillu and of Wiseмond Reade. It comes in bundles consisting of long, slender, crooked stems, with the bark generally attached, sometimes of the branches, but seldom of the whole plant. This is about six feet high, with a yellowish-orange bark, in some parts light-red, and covered by a gray efflorescence. The leaves are opposite, oval-acuminate, with a linear prolongation at the end more than an inch long. The precise botanical character of the plant is not known, but it is thought to be a Loganiacea. The active principle of the plant has been extracted by Dr. Thos. R. Fraser, and, having been found to possess the properties of the alkaloids, has been named by its discoverer *akazgia*. It is colourless, crystallizable with difficulty, soluble in 60 parts of cold absolute alcohol, 16 parts of officinal alcohol, 130 parts of anhydrous ether, and in 13,000 parts of water at 60° F. It is freely soluble in chloroform, bisulphuret of carbon, benzole, and ether of 0·735. The alcoholic extract of the plant acts on the system in a manner very similar to nux vomica; and the alkaloid has precisely the same physiological properties. (*Chem. News*, Oct. 18, 1867, p. 203.)

This is probably the same poison referred to under the name of *boundou* or *icaja*, by MM. Pecholier and Saint Pierre, who consider the plant producing it as belonging to the *Apocyneæ*, and state that it is used as an ordeal poison by the natives of Gaboon, in Africa. They extracted from it a poisonous principle, which, like that discovered by Dr. Fraser, resembled nux vomica in its action on the system. (See *Am. Journ. of Pharm.*, March, 1867, p. 124.) W.

ALBUMINATE OF IRON AND POTASSA, SYRUP OF. This syrup, proposed by M. Lassaigne, is made as follows. Dissolve 100 parts of white of eggs in 100 of distilled water, and precipitate the filtered solution with 36 parts of a solution of the tersulphate

of sesquioxide of iron, marking 5° of the areometer. Then add 2 parts of alcoholic potassa, previously dissolved in 50 parts of water. This, by agitation, will gradually dissolve the precipitate caused by the ferruginous solution, forming a deep orange-yellow liquid. The liquid is then converted into a syrup by dissolving in it one and a half times its weight of coarsely powdered sugar, and filtered. The syrup has a slightly alkaline and sweetish taste, totally devoid of inky flavour. Each fluidounce contains about six grains of anhydrous sesquioxide of iron. Mr. A. J. Cooley has proposed to make a simple *albuminate of iron* by dissolving the freshly precipitated oxides of iron in a filtered solution of albumen. B.

ALBUMINATE OF IRON AND SODA. Angelico Fabri, observing that simple contact of the white of eggs with a salt of iron and soda was sufficient to produce a soluble albuminate of iron and soda, the composition of which is so stable that it is not disturbed by ferrocyanide of potassium unless with the presence of an acid, and inferring that this is the condition in which the several ingredients of the compound exist in the blood, proposes this salt as likely to meet better than any other those wants of the system which call for the use of chalybeates. He prepares the salt by pouring upon the whites of four eggs, previously beaten up, solutions separately made of 112 grains of caustic soda and 104 of sulphate of iron in sufficient distilled water; shaking the mixture, and placing it on a filter to separate the excess of hydrated oxide of iron which has precipitated; adding lime-water to the filtrate to separate the sulphuric acid of the sulphate of soda which exists in the solution; again filtering, and precipitating the lime held in the solution by passing through it a stream of carbonic acid; filtering a third time to separate the carbonate of lime; and finally reducing the liquid with a moderate heat to the measure of a pint. A transparent orange-yellow solution is thus obtained, having a slightly saltish and chalybeate taste, and unaffected by ferrocyanide of iron unless with the presence of an acid. Each fluidounce contains 4 grains of the albuminate, with an excess of albumen and soda, which gives it an alkaline reaction, and renders it conformable to the state in which the compound exists in the blood. The albuminate of iron and soda is represented by the formula $C_{30}H_{50}O_{10}+HO+Fe_2O_3+NaO+2HO=Al,Fe_2O_3,NaO+2HO$. It may be obtained in radiated crystals by evaporating the salt to dryness. (*Am. Jour. of Pharm.*, Jan. 1863, p. 69; from *Journal of Rational Medicine*, May, 1862.) W.

ALCHEMILLA VULGARIS. *Ladies' Mantle.* A perennial European herb, growing in meadows, on the banks of rivulets, and in the borders of woods. The whole plant has an astringent, bitterish taste, which is strongest in the root. It was formerly employed in diarrhœa, and other complaints requiring the use of astringents. By the ancients it was highly esteemed; and extraordinary powers were ascribed to it by the alchemists, from whom, according to Linnæus, it derived its generic title. W.

ALCORNOQUE. Under this name a bark was introduced into Europe from South America, more than fifty years since, and for a short time attracted considerable attention. It has been conjecturally referred by different writers to different plants, but its precise origin is unknown. It is in large thick pieces, composed of two layers, of which the external is reddish, cracked, granular, spongy, and two or three lines in thickness, the internal lamellated, woody, and possessed of the quality of imparting a yellow colour to the saliva when chewed. It is inodorous. The outer layer is of an astringent, somewhat bitter taste, and was thought to have febrifuge powers; the inner is much more bitter, and is decidedly emetic. The bark was brought into notice chiefly as a remedy in phthisis; but, having been found useless in that complaint, has fallen into entire neglect. It was given in the form of powder, in the dose of thirty grains; or half an ounce of it was boiled in a pint of water down to half a pint, and two or three tablespoonfuls of the decoction were administered every two hours. In these doses it acted as an emetic. The bark known in Spain by the name of *alcornoque* is obtained from the cork-tree (*Quercus Suber*), and has sometimes been confounded in European pharmacy with that derived from South America. It has the properties of the ordinary oak barks. W.

ALEURITES TRILOBA, OIL OF. This is a small tree belonging to the Linnæan Class and Order Monœcia Monadelphia, and the Natural Order Euphorbiaceæ. It is widely diffused through the tropics, being indigenous in the East Indies and Islands of the Pacific, and naturalized in the West Indies. The fruit is a nut nearly as large as a walnut, consisting of a thick shell enclosing a kernel, which is rich in oil, and yields it readily by expression. The nuts, strung together on the fibres of the palm-leaf, are used in the South Pacific Islands as a substitute for candles. The oil has been long known in the various countries inhabited by the plant, being called in Jamaica *Spanish walnut oil*, in India *Belgaum walnut oil*, in Ceylon *kekune oil*, and in the Sandwich Islands *kukui oil*. It may be obtained by boiling with water the kernels previously beaten in a mortar, or by expression. Sixteen pints of kernels yield about three pints of oil. The yearly product of the Sandwich Islands is said to be 10,000 gallons. (M. C. Cooke, *Pharm. Journ.*, Nov. 1860, p. 282.) The oil has been used in the arts; but it is only of late that attention has been called to its medicinal qualities by Mr. O'Rorke. The following account of its properties and uses we take from *Bouchardat's Annuaire* (1859, p. 117). The oil is very fluid, of an amber colour, without taste or smell, congealing at 32° F., insoluble in alcohol, readily

saponifiable, "and very strongly drying." As a medicine it acts as a prompt and efficient but mild cathartic, without any tendency to produce nausea, vomiting, or griping pains and destitute of any other medical property. It seems to be admirably adapted to cases in which castor oil is used, and has the great advantage over that cathartic that it does not nauseate, and is very easily administered. The does is from one to two ounces; the smaller quantity generally answering. The cake left after the expression of the oil, given to a dog in the dose of about half an ounce, produced no vomiting, but acted strongly as a purgative. Should all that has been said of the oil prove correct upon further trial, it would be likely to supersede castor oil to a considerable extent. W.

ALISMA PLANTAGO. *Water Plantain.* A perennial herbaceous plant, common to Europe and the United States, and growing in streams, pools, ditches, and other standing waters. The *root* has when fresh an odour like that of Florentine orris, but loses it when dried. Its taste is acrid and nauseous. It acquired at one time considerable credit as a preventive of hydrophobia, for which purpose it was said to have been used with great advantage in Russia; but subsequent experiments have proved its total inefficacy. The Calmucks are said to use it for food. The *leaves* are rubefacient, and will sometimes even blister when applied to the skin. They have been recommended in gravel and complaints of the bladder, in the dose of a drachm. The root has recently been used in chorea and epilepsy with asserted advantage. The dose of the powdered root, at first about 8 or 10 grains morning and evening, is rapidly increased to a teaspoonful, and in the end carried to three or four spoonfuls in the course of the day. (*Ann. de Thérap.*, 1859, p. 62.) W.

ALKANET. This is the root of *Anchusa tinctoria*, or *dyers' alkanet*, an herbaceous perennial plant, growing in the Grecian Archipelago and the South of Europe. It is said in some medical works to be cultivated abundantly in the South of France; but another plant is probably referred to—*Lithospermum tinctorium* of Linnæus and De Candolle, *Anchusa tinctoria* of Lamarck—which is a native of that country, and the root of which is considered as the true alkanet by the French writers. Alkanet, as found in the shops, is in pieces three or four inches long, from the thickness of a quill to that of the little finger, somewhat twisted, consisting of a dark-red, easily separable bark, and an internal ligneous portion, which is reddish externally, whitish near the centre, and composed of numerous distinct, slender, cohering fibres. As it comes to us it is usually much decayed internally, very light, and of a loose, almost spongy texture. The fresh root has a faint odour, and a bitterish, astringent taste; but when dried it is nearly inodorous and insipid. Its colouring principle, which abounds mostly in the cortical part, is soluble in alcohol, ether, and the oils, to which it imparts a fine deep red; but is insoluble in water. It may be obtained by first exhausting the root with water, and then treating it with a weak solution of the carbonate of potassa or soda, from which the colouring principle may be precipitated by an acid. According to Pelletier, by whom it was discovered, it possesses acid properties, forming with the alkalies and earths neutral compounds, which are of a blue colour, and soluble in alcohol and ether. He calls it *anchusic acid*, and states that it may be sublimed unchanged. (*Journ. de Pharm.*, xix. 105.) The tincture of alkanet has its colour deepened by acids, changed to blue by alkalies, and again restored by neutralizing the latter substances. It may, therefore, be used as a test. The extract obtained by evaporating the tincture is dark-brown. Alkanet is somewhat astringent, and was formerly used in several diseases; but it is now employed exclusively for colouring oils, ointments, and plasters, which are beautifully reddened by one-fortieth of their weight of the root. It is said also to be used in the preparation of spurious port wine. W.

ALLIARIA OFFICINALIS. *Erysimum Alliaria.* Linn. *Hedge Garlic.* A perennial European herb, having an alliaceous odour when rubbed, and a bitterish, somewhat acrid taste. When eaten it communicates its smell to the breath. Mr. Wertheim obtained from the root a volatile oil, apparently identical with that of mustard. (*Ann. der Chem. und Pharm.*, liii. 52.) The herb and seeds are esteemed diuretic, diaphoretic, and expectorant, and have been given in humoral asthma, chronic catarrh, and other complaints in which garlic is useful. The herb has also been recommended as an external application in gangrenous affections, and to promote suppuration. W.

ALNUS GLUTINOSA. *Common European Alder.* A European tree, twenty-five feet or more in height, growing in swamps, on the sides of streams, and in other damp places. The bark and leaves are very astringent, and somewhat bitter. The former has been used in intermittent fever, the latter as a topical remedy in wounds and ulcers. The bruised leaves are sometimes applied to the breast for the purpose of repelling the milk. The cones also are astringent, and form a useful gargle in complaints of the throat. All these parts of the tree are used in dyeing, and the leaves and bark in tanning. The tannic acid, however, appears to differ from that of galls and oak bark, as, according to Dr. Stenhouse, it does not yield glucose when acted on by sulphuric acid. (*Pharm. Journ.*, Dec. 1861, p. 331.) *Alnus serrulata*, or common *American alder*, has analogous properties. W.

AMARANTHUS HYPOCHONDRIACUS. *Prince's Feather.* An annual plant growing spontaneously though sparingly in the Middle States, but believed to have been derived from tropical America. (*Gray's Manual*, p. 368.) It is cultivated in our gardens on account of its flowers, which are in densely crowded spikes, and of a deep-red colour

The leaves are said to be astringent, and to be used internally and topically in the complaints to which the astringents generally are applicable. W.

AMBERGRIS. *Ambra Grisea.* This substance, which is found floating on the sea, or thrown by the waves upon the shores of various countries, particularly in the southern hemisphere, is now generally believed to be produced in the intestines of the *Physeter macrocephalus*, or spermaceti whale, and perhaps in those of some other fish. It is in roundish or amorphous pieces, usually small, but sometimes of considerable magnitude; and masses have been found weighing 50, 100, and even 200 pounds. These pieces are often composed of concentric layers. They are of various colours, usually gray, with brownish, yellow, and white streaks, often dark-brown or blackish on the external surface. They are opaque, lighter than water, and of a consistence like that of wax. Ambergris has a peculiar aromatic agreeable odour, is almost tasteless, softens with the warmth of the hand, melts under 212°, is almost completely volatilizable by heat, and is inflammable. It is insoluble in water, but is readily dissolved, with the aid of heat, by alcohol, ether, and the volatile and fixed oils. It consists chiefly of a peculiar fatty matter analogous to cholesterin, and denominated by Pelletier and Caventou *ambrein.* This may be obtained by treating ambergris with heated alcohol, filtering the solution, and allowing it to stand. Crystals of ambrein are deposited. It is incapable of forming soaps with the alkalies. When pure it has little or no odour. Ambergris is often adulterated; but does not then exhibit its ordinary fusibility and volatility. It was long regarded as a cordial and antispasmodic, somewhat analogous to musk; and has been recommended in typhoid fevers, and various nervous diseases. It formerly entered into many officinal preparations, and is still retained in some European Pharmacopœias. The French Codex directs a tincture to be prepared by macerating, for ten days, 100 parts of powdered ambergris with 1000 parts of alcohol at 80°, expressing and filtering. M. Stan. Martin assures us that the tincture will keep better, deposit nothing, and have a more agreeable odour, if the ambergris, instead of being merely powdered in a mortar, be subjected to porphyrization, especially with the addition of washed sand. Heat, he says, should never be used in its preparation. (*Journ. de Pharm.*, 4e sér., i. 448.) It is, however, feeble as a remedy, and is much more used in perfumery than in medicine. The dose is from five grains to a drachm. W.

AMBROSIA TRIFIDA. *Ragweed.* (*Gray's Manual*, p. 212.) This and another indigenous species, *A. artemisiæfolia*, both annual plants, and usually ranked among worthless weeds, have found a place in the Materia Medica of the eclectics, by whom they are deemed astringent and somewhat exciting, and are given in low forms of fever, and other conditions of the system in which the vital actions are enfeebled. W.

AMMONIATED IRON. FERRUM AMMONIATUM. *Ammoniated Iron. Ammonio-chloride of Iron.* Though discharged from the officinal lists at the late revisions of the Pharmacopœias, this preparation has too long occupied a conspicuous place in the Materia Medica to justify its omission in a work of this kind. It was recognised until recently both by the U. S. and London Pharmacopœias, which contained formulas for its preparation. The following was the U. S. process. "Take of Subcarbonate of Iron *three ounces;* Muriatic Acid *ten fluidounces;* Muriate of Ammonia *two pounds and a half;* Distilled Water *four pints.* Mix the Subcarbonate of Iron with the Muriatic Acid in a glass vessel, and digest for two hours; then add the Muriate of Ammonia, previously dissolved in the Distilled Water, and, having filtered the liquor, evaporate to dryness. Rub the residue to powder." (*U. S.*) The process of the *London College* was essentially the same as the above, of which, in fact, it was the original. By the mutual action of muriatic acid and the sesquioxide of iron of the subcarbonate, water and sesquichloride of iron are formed; and the solution of the latter, being evaporated along with that of the muriate of ammonia, yields a mixture of the two salts. If any carbonate of iron be present in the subcarbonate, a portion of protochloride of iron must also be formed, which, however, would probably be converted into sesquichloride during the operation. The preparation was formerly made by subliming a mixture of red oxide (sesquioxide) of iron and muriate of ammonia. A portion of the muriate of ammonia was decomposed; the ammonia escaping, and the muriatic acid reacting upon the sesquioxide of iron so as to form water and sesquichloride of iron, the latter of which was sublimed with the undecomposed muriate of ammonia. By this mode of preparation the proportion between the two salts was variable. The late officinal plan has the double advantage of uniformity in the result, and greater facility in the process. There is no reason to believe that the sesquichloride of iron and muriate of ammonia are chemically combined in the preparation. According to Mr. Phillips, they are in the proportion of 15 parts of the sesquichloride to 85 of the muriate.

Properties. Ammoniated iron, thus prepared, is in crystalline grains, of a fine reddish-orange colour, and a sharp, styptic, saline taste. It is entirely soluble in water and diluted alcohol, is deliquescent, and should be kept in well-stopped bottles. By the alkalies and their carbonates, and by lime-water it is decomposed, with the precipitation of about 7 per cent. of sesquioxide of iron; and potassa in excess occasions the evolution of ammonia. Like the other chalybeates, it is incompatible with vegetable astringents.

As procured by sublimation, it is of a yellow colour and feeble odour, and is probably the result of a chemical reaction between the ingredients.

Medical Properties and Uses. This preparation unites aperient properties with those belonging to the chalybeates generally, and is said to have been used with advantage in amenorrhœa, epilepsy, scrofula, rickets, &c.; but it is at best uncertain, and is now very seldom prescribed. The sublimed preparation was formerly employed under the names of *flores martiales* and *eus martis*. From four to twelve grains may be given in the form of pill, electuary, or solution, several times a day. W.

AMPELOPSIS QUINQUEFOLIA. *Virginia Creeper. American Ivy.* (*Gray's Manual*, p. 78.) This woody creeper, which is a common indigenous plant, and conspicuous in autumn by its bright crimson leaves, has been used by the "eclectics" as an alterative, tonic, and expectorant. The bark and twigs are the parts employed. The remedy has been recommended by Dr. J. McCall, in the *Memphis Journal of Medicine*, in the treatment of dropsy. He believes it to act rather by stimulating absorption than as a diuretic. Dr. McCall employs the bark collected late in the fall, and exhibits it in the state of decoction or infusion. (*Penins. and Independ. Med. Journ.*, June, 1858, p. 169.) W.

AMYLEN. *Valeren.* This compound was alluded to under amylic alcohol, *page* 85 It is an iso-equivalent carbohydrogen, having the formula $C_{10}H_{10}$. Amyl is $C_{10}H_{11}$, and amylic alcohol (fusel oil) is the hydrated oxide of amyl $C_{10}H_{11}O+HO$, or the bihydrate of amylen $C_{10}H_{10}+2HO$. Amylen was discovered by M. Balard, of Paris, in 1844. It is prepared by distilling amylic alcohol with a concentrated solution of chloride of zinc. The product is redistilled, and that which comes over first, constituting the more volatile part, is separately collected, and agitated with concentrated sulphuric acid, when the amylen, freed from water, will rise to the surface. Amylen is a colourless, very mobile liquid, having the density 0·695 at 56°. Its boiling point is 102° (95° *Dumas*) and the density of its vapour 2·45. Its smell is peculiar and disagreeable. It is soluble in alcohol and ether, in all proportions, but very sparingly so in water. When pure it does not act on potassium, and is not coloured by a prolonged contact with caustic potassa.

Amylen was proposed as a new anæsthetic by Dr. Snow, in a paper read before the London Medical Society on the 10th of Jan. 1857. The advantages claimed for it, compared with other anæsthetics, were that its vapour is less pungent; that it abolishes pain with a stupor less deep; and that there is no struggling on the part of the patient, and no sick stomach after its administration. Its bad smell was admitted as an objection. These alleged advantages have not been found to counterbalance the dangers of its use. Dr. Snow admits "the absolute safety which seems to attend sulphuric ether under all circumstances;" an admission which makes it less necessary to seek for a new anæsthetic. Already, within the brief period during which it has been tried, two deaths have occurred, although the amylen was administered by Dr. Snow himself. The French Academy of Medicine, after a deliberate examination of its alleged advantages, have condemned it as dangerous. From a chemical examination of various specimens of commercial amylen, as well as of the purest form of it as prepared by the process of M. Balard, Dr. Schauenstein has found that they all contain chlorine; and the uncertainty thus thrown upon the nature of the compound adds to the motives, previously existing, for abandoning the use of it as an anæsthetic agent. (See *B. and F. Med.-chir. Rev.*, Am. ed., Jan. 1858, p. 193.)

Hydruret of Amyl (hydride of amyl), $C_{10}H_{11}H$, is another new anæsthetic, proposed by Prof. Simpson, of Edinburgh. It was discovered by Dr. E. Franklin, of Manchester, who obtained it by a complicated process, which has been rendered more easy of execution by Messrs. T. & H. Smith, of Edinburgh, who prepared the substance at the request of Prof. Simpson. (See T. & H. Smith's paper, in the *Pharm. Journ.*, June, 1857.) Hydruret of amyl is a colourless, volatile, mobile liquid, possessing a grateful fruity odour, but no taste. It is the lightest liquid known, having the sp. gr. 0·638 at 57°. It boils at 86°, and the density of its vapour is 2·5. It is very inflammable, and burns with a brilliant white flame. It is readily soluble in alcohol and ether, but insoluble in water. "It is a very stable compound, resisting the action of fuming sulphuric acid and the most powerful oxidizing agents." We have not seen any precise account of its mode of action as an anæsthetic. B.

Besides the hydruret of amyl, other compounds have been examined by Dr. B. W. Richardson, of London, among which are *amylic alcohol*, the *iodide*, the *acetate*, and the *nitrite*. Of these the nitrite is the most energetic, and has been brought into special notice by Dr. Richardson.

Nitrite of Amyl. This is an inflammable liquid, lighter than water, boiling at 182° F., having a fruity pear-like odour, and the composition $C_{10}H_{11}.NO_3+HO$. (*B. and F. Med.-chir. Rev.*, Oct. 1866, p. 450.) It may be prepared by heating fusel oil gently, in a retort, with nitric acid, removing the heat as soon as bubbles form, repressing effervescence if too strong by cold water, rectifying from potassa the distillate passing over under 212° F., and collecting apart the product which distils under 177° F. (*Gmelin*, xi. 63.) From the experiments of Dr. Richardson on animals, it appears to find entrance into the system from any point of application. When inhaled it acts immediately as a powerful stimulant to the heart, more powerful, indeed, than any other known agent; and a little of it

applied to the nostrils causes an instantaneous and extraordinary flushing of the face. This excitement of the heart is followed by diminished but not extinguished power of that organ, and contraction of the external vessels. Given to animals by inhalation, it is capable of suspending respiration, and producing death; but, short of the latter result, it may produce, when properly regulated, a reduction of the respiration and circulation so extreme, that a condition analogous to *trance* may be induced and sustained for many hours. It does not seem to have anæsthetic properties. Consciousness is never lost unless a state of approaching death is induced, from which the animal rarely if ever recovers. Its force is directed especially to the muscular action, which it first "wildly excites" and then subdues. The appearances after death differ according to the mode in which the fatal effect has been produced. If the nitrite be given very rapidly, the lungs and brain are free from congestion and even blanched, and the left side of the heart is empty, though the right cavities are engorged with blood. If slowly administered, it leaves a congested state of the lungs and brain, and blood is found in both sides of the heart. No distinction of colour is observed between the arterial and venous blood. Notwithstanding the violent action of the heart, Dr. Richardson has never known it to cause rupture of a blood-vessel, or extravasation. Though no therapeutic use of this fluid has yet been made, so far as we know, yet its extraordinarily rapid and powerful action on the heart suggests important applications of it in threatening cases of syncope, and others of great failure in the heart's actions.

In relation to *amylen*, Dr. Richardson observed that, though it is capable of producing insensibility, this is attended with a kind of consciousness, leading to certain actions, of which there is no remembrance after awaking. *Amylic alcohol*, when inhaled by men or the lower animals, produces a state of muscular paralysis with paroxysms of convulsive trembling, which are excited by the slightest cause, as a simple touch, or breathing on the surface. *Iodide of amyl* acts similarly to amylic alcohol, with this superadded symptom, that when the animal begins to move, whether spontaneously or under excitation, he does so for a considerable time in a circle. The *acetate of amyl* exerts an influence similar to those of the nitrite and iodide, but less marked. All of these compounds have the property of preventing putrefaction in vegetable substances. None of them can be used as anæsthetic agents; as they do not, like the compounds of formyl or ethyl, produce general insensibility to pain. (*B. and F. Med.-chir. Rev.*, Jan. 1867, p. 245.) W.

ANACAHUITE WOOD. Under this name, in the year 1860, considerable quantities of a peculiar wood were imported from Tampico, in Mexico, into Germany, where for a short time it attracted great attention as a supposed remedy in phthisis. The circumstance that the wood was destitute of taste and smell naturally suggested that it could possess little remedial power; and frequent trials of it in consumptive affections have ended in failure; so that the wood is likely to be forgotten almost as speedily as brought into temporary notoriety. In the mean time, the question of its botanical origin attracted the attention of pharmacologists; and the question has been at length determined by the importation of a living specimen of the tree into Germany, which partially flowered in the botanical garden of Göttingen. This, with dried specimens received from Mexico, enabled the botanists to decide that the wood was the product of the *Cordia Boissieri* of Alphonse De Candolle. (See *Pharm. Journ.*, Dec. 1862, p. 272, where the plant is figured.) W.

ANACARDIUM OCCIDENTALE. Linn. *Cassuvium pomiferum*. Lam. *Cashew-nut*. A small and elegant tree, growing in the West Indies, and other parts of tropical America. A gum exudes from the bark, which bears some resemblance to gum arabic, but is only in part soluble in water, and consists of true gum and bassorin. It is the *gomme d'acajou* of the French writers. The fruit is a fleshy, pear-shaped receptacle, supporting at its summit a hard, shining, ash-coloured, kidney-shaped nut, an inch or more in length, and three-quarters of an inch broad, consisting of two shells, with a black juice between them, and of a sweet oily kernel. The receptacle is red or yellow, and of an agreeable subacid flavour with some astringency. It is edible, and affords a juice which has been recommended in uterine complaints and dropsy. This juice is converted by fermentation into a vinous liquor, which yields a spirit by distillation, used in making punch, and said to be powerfully diuretic. The nuts are well known under the name of *cashew-nuts*. The black juice, contained between their outer and inner shell, is extremely acrid and corrosive, producing, when applied to the skin, severe inflammation, followed by blisters or desquamation. It has been examined chemically by Stoedeler, who found in it two peculiar principles, one having acid properties, which he calls *anacardic acid*, and the other a yellow, oleaginous liquid, named *cardol*. (See *Journ. de Pharm.*, 3e sér., xiii. 459.) The juice is used in the West Indies for the cure of corns, warts, ringworms, and obstinate ulcers, and is said to be sometimes applied to the face by females, in order to remove the cuticle, and produce a fresher and more youthful aspect. In a case of external poisoning which came under our notice, in a lady who was exposed to the fumes of the nut while roasting, the face was so much swollen that for some time not a feature was discernible. A similar case, occurring in a boy who had cut open one of the nuts, eaten a small portion raw, and by handling it had spread the juice over different parts of the body, is recorded by Dr. Monkur in the *N. J. Med. Reporter* (April, 1855, p. 187). The tongue, face, neck, hands, forearms, scrotum, &c. were red and enormously swollen, and very painful. The tincture of iodine was found useful as a

local application to the parts affected. The kernel has a sweet, agreeable taste, and is eaten like chestnuts, either raw or roasted. It is also used as an ingredient of puddings, &c., and forms an excellent chocolate when ground with cocoa. By age it becomes rancid. The black juice of the nut, and a milky juice which flows from the tree by incision, are sometimes used for marking linen, upon which they leave a nearly indelible brown or black stain. W.

ANAGALLIS ARVENSIS. *Scarlet Pimpernel.* An annual plant, growing in Europe and this country, with small, delicate, procumbent stems, furnished with opposite branches, opposite ovate leaves, and small scarlet flowers, which are supported upon axillary, solitary peduncles, and appear in June and July. It has little smell, but a bitterish, somewhat acrid taste. The ancients esteemed it a counter-poison, and in modern times it has been used as a preventive of hydrophobia; but at present no faith is placed in its alexipharmic powers. It is, nevertheless, not wholly inactive; as Orfila found three drachms of an extract prepared from it sufficient to destroy a dog, with marks of inflammation of the bowels. It has been recommended as a local application to old and ill-conditioned ulcers, and has been given internally in visceral obstructions, consumption, dropsy, epilepsy, mania, &c. But too little is known of its precise properties, to authorize its indiscriminate employment in these complaints. Mr. J. A. Heintzelman obtained a small quantity of volatile oil from the dried herb, and found it of a strong peculiar odour, a pungent and somewhat acrid taste, and the sp. gr. 0·987. Four drops of it produced intense headache and nausea, which continued for 24 hours, with pains throughout the body. Another species, considered by Linnæus as a variety of A. arvensis, is *A. cærulea*, distinguished by its blue flowers. The medical properties of the two, so far as is known, are the same. W.

ANCHUSA OFFICINALIS. *Bugloss.* This species of Anchusa is a native of Europe, and unknown in the United States. It is a biennial plant, from one to three feet high, and was formerly much esteemed as a medicine. The root, leaves, and flowers were officinal. These are inodorous and nearly tasteless. The root is mucilaginous and slightly sweetish, and the flowers very feebly bitter. The plant has no claim whatever to the credit, formerly attached to it, of possessing cordial and exhilarating properties. It was used by the ancients in hypochondriacal affections; but, as it was given in wine, the elevation of spirits was probably due to the vehicle. In France, the *Anchusa Italica*, which is there known as *buglosse*, is employed for the same purposes and in the same manner as Borago officinalis. (See *Borago officinalis* in *Part* III.) W.

ANDROMEDA ARBOREA. *Sorrel-tree.* A beautiful indigenous tree, growing in the valleys of the Alleghanies, from Pennsylvania to Florida. The leaves have a pleasant acid taste, which has given rise to the common name of the tree. They are used by hunters to allay thirst, and form in decoction a grateful refrigerant drink in fevers. The other species of Andromeda are shrubs, and some of them ornamental. Dr. Barton, in his "Collections," states that a decoction of *A. Mariana* is employed in the Southern States, as a wash in a disagreeable ulceration of the feet to which the negroes are liable. The powder upon the leaves and buds of *A. speciosa* is said to be a powerful errhine. W.

ANEMONE PRATENSIS. *Meadow Anemone.* This plant enjoyed at one time considerable credit from the recommendation of Störck, who believed that he found it useful in amaurosis and other complaints of the eye, in secondary syphilis, and in cutaneous eruptions. Dr. J. de Ramm found it also very useful in hooping-cough. *A. Pulsatilla* (*pulsatilla*), an analogous species, has been employed for similar purposes; and favourable reports have been made of its efficacy in obstinate diseases of the skin, and in hooping-cough. It has been supposed also to possess emmenagogue properties, and to exert an alterative influence over the mucous membranes; rendering it useful in ophthalmia, in catarrhal inflammation of the nostrils, throat, and respiratory passages, and in similar conditions of the alimentary canal and urinary organs. The preparation employed by Störck was an extract of the herbaceous part of the plant, which was given in the dose of one or two grains daily, gradually increased to twenty grains or more. The dried herb, and a tincture and distilled water of the plant were used; the dose of the powder being two or three grains, of the tincture half a fluidrachm, and of the water two or three drachms. In large doses it was found frequently to produce nausea and vomiting, or griping and looseness of the bowels, and sometimes acted as a diuretic. It is, we believe, a favourite remedy with the homœopathists. For a more particular account of the uses of pulsatilla, the reader is referred to an article by Dr. J. C. Peters, of N. York, in the *Bost. Med. and Surg. Journ.* (Aug. 29, 1867, p. 77). The species of Anemone above mentioned are European plants, and are not cultivated in this country. We have several native species. One of them, *A. nemorosa*, which is common to Europe and the United States, is said to act as a poison to cattle, producing bloody urine and convulsions. It is stated also to have proved, when applied to the head, a speedy cure for tinea capitis. Most of the species are, in the recent state, acrid and rubefacient, resembling in this respect other Ranunculaceæ. They contain a peculiar crystallizable principle, named *anemonin*, convertible into *anemonic acid* by the action of alkalies. (*Ann. der Pharm.*, xxxii. 276.) It is deposited by water distilled from the fresh herb upon standing, and resembles camphor. According to J. Müller, it is formed by a metamorphosis of the acrid matters which are distilled with the water. (*Pharm. Cent.*

Blatt, Sept. 11, 1850, p. 618.) M Dobraschinky obtains it by a method founded on its solubility in chloroform. The distilled water of Anemone pratensis is agitated with one-tenth of this liquid, with which it is continued in contact for some hours; the liquid on standing separates into two layers, the heavier of which, containing the chloroformic solution, is distilled. The chloroform passes, and the residue, constituting one-eighth of the solution, is treated with strong alcohol, heated, and set aside to crystallize. Anemonin separates in handsome crystals having all the properties of that very poisonous alkaloid. (*Journ. de Pharm.*, 4e sér., i. 319.) The *A. Ludoviciana*, an American species, growing in Minnesota and other parts beyond the Mississippi, has been employed with supposed advantage by Dr. W. H. Miller, of St. Paul, in chronic diseases of the eyes, in cutaneous eruptions, and syphilitic affections. Mr. A. W. Miller, having submitted the plant to chemical examination, succeeded in obtaining anemonin from it. (*Am. Journ. of Pharm.*, July, 1862, p. 300.) W.

ANGRÆCUM FRAGRANS. This is an orchideous plant, indigenous in the Isle of Bourbon and Mauritius, where the leaves have been long used, under the name of *faham*, for the same purposes as Chinese tea, to which they are preferred by the natives of these islands. They have a somewhat pungent aromatic taste, and a strong and highly agreeable odour, scenting the whole apartment with a delicious perfume. Given in infusion, they appear to have an effect on the system somewhat similar to that of Chinese tea, and have recently been introduced into Paris, as a rival of that popular beverage The drink is made by putting the leaves and stalks, in the proportion of 15 grains to a teacupful, into cold water, boiling for about ten minutes, and then pouring into a closed vessel, and sweetening it when used. (*Am. Journ. of Pharm.*, Sept. 1866, p. 441.) W.

ANILIN. *Aniline. Anilia.* This is an organic alkaloid obtained from coal tar. It was first discovered by Unverdorben, in 1826, among the products of the dry distillation of indigo, and was named by him *crystalline*. Fritzshe, who obtained it afterwards from indigo by another process, seems to have been the first to give it the name of anilin. In 1837 Runge obtained three volatile principles from coal tar, which he named *kinol*, *leucol*, and *pyrrhol*. Of these, kinol was afterwards found by Hoffmann to be identical with anilin, and leucol has been ascertained to be the same as quinolin (cincholin). (See *page* 302.) Nitrobenzole has also been made to yield anilin by various processes; and this and coal tar are its chief practical sources. When coal tar is distilled, a set of the more volatile principles first come over, and, when condensed in the liquid form, constitute the *light oil of tar*. This includes benzole. Afterwards, another set come over, heavier, and with a higher boiling point, and these are all embraced under the name of the *heavy oil of tar*. Among these are anilin, quinolin, creasote, phenol, &c. After these follow other substances having when condensed a buttery consistence, among which are paraffin, &c. The heavy oil comes over between the temperatures of 300° and 450° F. At a higher heat than about 480° F. anilin is no longer found among the results of distillation. Hoffmann procures anilin in the following manner. The heavy oil already referred to is agitated with muriatic acid, and set aside for 12 or 14 hours. The liquid separates into an oily and an acid layer. The latter is separated and agitated with another portion of oil, though not to full saturation. The acid liquid containing the alkaloids in the form of muriates, having been filtered to separate all the oil, is mixed with an excess of lime and distilled. A milky liquid comes over containing the alkaloids, and anilin among them. These are again saturated with diluted muriatic acid, and the solution, after being concentrated by a water-bath, is treated with a slight excess of soda or potassa. The bases then set free float on the surface of the liquid, and, having been removed by a pipette, are rectified by distillation. The distillate which first comes over, at a heat short of 400° to 420° F., is anilin sufficiently pure for commercial purposes. Beyond the latter heat it is principally quinolin that comes over. To get anilin chemically pure, oxalic acid in alcoholic solution is added to the impure alkaloid. Oxalate of anilin is thrown down as a mass of white crystals. This is washed with alcohol, pressed, and then dissolved in water with a little alcohol, from which the oxalate crystallizes on concentration. The oxalate is decomposed by a caustic alkali, and the anilin, thus set free, is distilled once more. Water first comes over, then water with some anilin, and lastly pure anilin. (See *Am. Journ. of Pharm.*, Jan. and March, 1861, pp. 39 and 129, for the abstract of a paper by M. E. Kopp, abridged from the *Moniteur Scientifique*, t. ii. liv. 86.) For the mode of preparing anilin from nitrobenzole, the reader is referred to a paper by Prof. Procter in the *Am. Journ. of Pharm.*, July, 1862, p. 296; also to a memoir by MM. Depoully, translated in the *Chem. News*, Oct. 5, 1866, p. 157.)

Properties. Pure anilin is a thin colourless fluid, of an oily appearance; but as found in the shops it is generally more or less coloured, and sometimes of a deep reddish-brown. It has a peculiar not disagreeable odour, and a pungent, aromatic, burning taste, and the sp. gr 1·020 (*Hoffmann*), 1·028 (*Fritzshe*). It is not solidified at —4° F., boils at 360°, and its vapours are condensed unchanged. It is slightly soluble in water. Though possessed of strong basic powers, it does not restore the colour of reddened litmus, nor does it redden turmeric. It changes, however, the violet colour of dahlias to green. With the acids it forms soluble and readily crystallizable salts. It is inflammable, and absorbs oxygen from the air, becoming at first yellowish, afterwards reddish, and ultimately brown. A characteristic

property is that it produces instantly a deep-blue or purple colour when brought into contact with chlorinated lime or other hypochlorite. Dr. Letheby has described a very delicate test for this alkaloid. If a drop of a very weak solution of the sulphate be placed on a piece of clean platinum foil, and touched with the negative pole of a galvanic battery, the solution acquires a bluish, then a violet, and ultimately a pink colour. (*Pharm. Journ.*, Sept. 1862, p. 128.) It consists of carbon, hydrogen, and nitrogen; its formula being $C_{12}H_7N$. The chief value of anilin at present is for the colouring matters derived from it. Beautiful reds, purples, yellows, and blues, and various other tints are obtained from it, some of them truly magnificent. (See *Am. Journ. of Sci. and Arts*, May, 1863, p. 417.) An anilin black has also been obtained, but by a process somewhat different from that used for the other colours. (*Chem. News*, Feb. 10, 1865, p. 65.) Some of these colours are advantageously used in the preparation of inks. For the mode of making from them inks of different hues, even a black indelible ink, the reader is referred to the *Am. Journ. of Pharm.*, July, 1868, pp. 332 and 335. Anilin colours have been advantageously employed by Dr. J. J. Woodward, U. S. A., in histological researches; as they have the property of permanently colouring the cells and cell-derivatives of animal structures, without affecting the other constituents. For general use, he prefers the anilin red, and dissolves it in dilute acetic acid, or sometimes in water. (*Am. Journ. of Med. Sci.*, Jan. 1865, p. 106.) Böttger uses anilin red in detecting cotton in any fabric with which it is mixed. He dips a portion of the texture in an alcoholic solution of this colouring matter, then washes it with water till the washings are colourless, and puts it into a watery solution of ammonia. If cotton be present, its threads will be deprived of colour, while the linen will continue of a bright rose colour. (See *Am. Journ. of Pharm.*, Jan. 1866, p. 86.)

Medical Properties and Uses. Anilin is said by Wöhler and Frerichs to have no poisonous action on dogs. This is, however, contradicted by the experiments of Dr. Letheby, who found that from 20 to 60 drops given to dogs and cats caused a rapid loss of respiratory powers, passing into coma, and ending in death. (*Guy's Hosp. Reports*, A. D. 1864, p. 198.) Some experiments have been made which show that it has a deleterious influence on leeches and frogs, and young rabbits were killed by it; but these prove nothing as to its effects on man. A case is on record in which a workman having been exposed strongly to the vapours of anilin, in consequence of a vessel containing it having broken and spilled the contents over his person, was seized with symptoms of great prostration, from which, however, he recovered under stimulating treatment. (*Med. Times and Gaz.*, June 7, 1862.) Several other instances have since occurred, in which persons inhaling the vapour of anilin in the process of manufacture have been seriously affected; the prominent symptoms being violent attacks of neuralgia, heaviness in the head, giddiness, and apparent prostration, sometimes confining the workmen to bed for days; but in all instances recovery took place, leaving, so far as appears, no serious evil behind; showing that the action of the poison is directed mainly, if not exclusively, to the nervous system. (*B. & F. Med.-chir. Review*, April, 1866, p. 539.) It would seem, however, from the experiments of Dr. Letheby, that the salts of anilin are destitute of the poisonous properties of the pure alkaloid; though a change of colour is sometimes produced by them; a patient who had taken a considerable quantity of the sulphate having his skin, nails, and gums stained yellow. The colour, however, disappeared in a few days. (*Journ. de Pharm.*, 4e sér., iii. 397.) Some of the anilin colours, or those derived from substances belonging to the same series, used in dyeing, are said to have a violently irritant effect upon the skin to which the fabric dyed with them may be brought into contact; and, in some instances, constitutional effects seem to have been induced. For further observations on this point, see the article on *coralline*, in the present part of the *Dispensatory*. Dr. Turnbull, of Liverpool, has employed the sulphate remedially, and speaks favourably of its effects in chorea. A remarkable effect which he found it to produce was a transient blueness of the skin and lips, which he ascribed to the oxidation of anilin in the blood. (*Pharm. Journ.*, Nov. 1861, p. 284.) In some instances headache and symptoms of general depression were experienced, which, however, disappeared without leaving any unpleasant effect. The sulphate is made by simply saturating the alkaloid with the acid. Prof. Procter gives the following formula. Take 500 grains of pure anilin, 250 grains of sulphuric acid, and 4 fluidounces of distilled water. Mix the acid and water, add the anilin, and agitate till a thick mass is formed, and the odour of anilin is lost. Wash this with strong alcohol till the acid and colouring matter are removed, press the salt in bibulous paper, and dry it in the dark. (*Am. J. of Pharm.*, July, 1862, p. 298.) The salt is liable to be decomposed, and to change colour when exposed to air and light. Water at 60° dissolves about 6 per cent. It is only sparingly soluble in cold, but freely in hot absolute alcohol. It is more soluble in diluted alcohol, and insoluble in ether. The limits of the dose have not been satisfactorily determined. It has been given in the dose of three-fourths of a grain gradually increased to four or even seven grains, without any derangement of the functions, except the change of colour above referred to; but how far the latter dose may be exceeded with impunity has not been ascertained. (*Ann. de Thérap.*, 1864, p. 101.) From trials which have been made of the remedy by Drs. Fraser and Davis, it has been inferred that the sulphate is much less powerful than the free alkaloid; and it is even stated that, while anilin itself is a powerful poison, the sulphate has little effect on the system. (*Pharm. Journ.*, Sept.

1863, p. 133.) Since the statements here made, the sulphate of anilin has been used in chorea and epilepsy with varying success. After failure in several cases of chorea, Dr. Fraser treated the disease successfully in two cases of a rather unpromising character, giving 5 grains of the sulphate three times a day. About half an hour after the medicine was taken, the mucous membrane of the mouth, and the nails became of a mauve colour, which increased for about two hours, and then disappeared. The patients complained more or less of headache and giddiness in the course of the treatment. In one of them 200 grains of the medicine were taken in about three weeks. (*Med. Times & Gaz.*, Aug. 1865, p. 142.) Dr. Filiberti, of Lyons, gives the sulphate with encouraging results in chorea and epilepsy. Beginning with a grain and one-half daily in two doses, he increases by the same amount daily till the dose reaches 15 grains, when he diminishes it in the same proportion till reduced to from 3 to 7 grains daily, which is continued. (*Ann. de Thérap.*, 1865, p. 124; from *Gaz. Méd. de Lyon.*) W.

ANIMÉ. *Gum Animé.* The substance known at present by the name of animé is a resin supposed to be derived from the *Hymenæa Courbaril*, a tree of South America; though this origin is denied by Hayne. According to Dr. W. Hamilton, the resin exudes from wounds in the bark, and is found also underneath the surface of the ground, between the principal roots. (*Pharm. Journ.*, vi. 522.) It is in small, irregular pieces, of a pale lemon-yellow colour, sometimes inclining to reddish, more or less transparent, covered with a whitish powder, brittle, and pulverizable, with a shining fracture, a weak but agreeable odour, and a mild, resinous taste. It softens in the mouth, adheres to the fingers when in powder, and readily melts with heat, diffusing its agreeable odour in an increased degree. It consists of two resins, one soluble, the other insoluble in cold alcohol, and of a small proportion of volatile oil. There is a variety of a darker colour, less transparent, and with small cavities in the interior; in other respects resembling the preceding. Another variety is the East Indian, supposed to be derived from *Vateria Indica;* but this never reaches us as a distinct article of commerce. Animé formerly entered into the composition of various ointments and plasters; but is now used only as incense, or in the preparation of varnishes. The Brazilians are said to employ it internally in diseases of the lungs. W.

ANNOTTA. *Orleana.* The colouring substance called *annotta, arnotta,* or *roucou,* is the reddish pulp surrounding the seeds in the fruit of *Bixa Orellana*, a middling-sized tree growing in Guiana, and other parts of South America. For a paper on the cultivation of this tree and the mode of preparing the annotta, by Mr. Th. Peckolt, see *Am. Journ. of Pharm.* (July, 1859, p. 360). The pulp is separated by bruising the fruit, mixing it with water, then straining through a sieve, and allowing the liquid to stand till the undissolved portion subsides. The water is then poured off, and the mass which remains, having been sufficiently dried, is formed into flat cakes or cylindrical rolls, and sent into the market. Another mode is to bruise the seeds, mix them with water, and allow the mixture to ferment. The colouring matter is deposited during the fermentation, after which it is removed and dried. In commerce there are two kinds of annotta, the Spanish or Brazilian, and French; the former coming in baskets from Brazil, the latter in casks from French Guiana. The French, which is also called *flag annotta*, has a disagreeable smell, probably from having been prepared by the fermenting process; but is superior, as a dye-stuff, to the Spanish, which is without any disagreeable odour. Annotta is of a brownish-red colour, usually rather soft, but hard and brittle when dry, of a dull fracture, of a sweetish peculiar odour, and a rough, saline, bitterish taste. It is inflammable, but does not melt with heat. It softens in water, to which it imparts a yellow colour, but does not dissolve. Alcohol, ether, the oils, and alkaline solutions dissolve the greater part of it. It contains a peculiar crystallizable colouring principle, to which M. Preisser, its discoverer, gave the name of *bixin.* (See *Journ. de Pharm.*, 3e sér., v. 258.) The chief uses to which annotta is applied are for dyeing silk and cotton orange-yellow, and for colouring cheese. The colour, however, which it imparts to cloth, is fugitive. It has been given internally as a medicine; but is not now used, and probably exercises little influence upon the system. In pharmacy it is used to colour plasters, and has occasionally been substituted for saffron. It is said to be sometimes largely adulterated; and red ochre, powdered bricks, colcothar, farinaceous substances, chalk, sulphate of lime, turmeric, &c., have been employed for the purpose. The mineral substances, if present, will be left behind when the annotta is burned. (See, in reference to its adulteration, *Pharm. Journ.*, xv. 199, 299, and 323.) W.

ANTENARIA MARGARITACEA. This is one of our indigenous plants which are known commonly by the name of *life-everlasting.* It is an herbaceous plant, a foot or two in height, and grows everywhere in the U. States northward of N. Carolina. For a description of the plant, see Gray's Manual of Botany (p. 229). The flowers are of a pearly whiteness, and slightly fragrant. The leaves are the part used, having the credit, with the "eclectics," of being somewhat astringent and expectorant. W.

ANTHRAKOKALI. This preparation, introduced by Dr. Polya, is of two kinds, the simple and the sulphuretted. The *simple anthrakokali* is formed by adding 160 parts of porphyrized mineral coal to 192 parts of a concentrated and boiling solution of caustic potassa, contained in an iron vessel, the whole being well stirred together. When the mixture is completed, the vessel is taken from the fire, and the stirring continued until the whole

is converted into a homogeneous black powder. The *sulphuretted anthrakokali* is prepared in a similar manner, 16 parts of sulphur being mixed with the mineral coal before it is added to the caustic potassa solution. Dr. Polya recommends these preparations, both internally and externally, in scrofula, chronic rheumatism, rheumatic tumours of the joints, and certain herpetic affections. The dose is a grain and a half three or four times a day, mixed with two or three times its weight of powdered liquorice root. For external use, sixteen grains may be rubbed with an ounce of lard to form an ointment, to be used by friction night and morning. B.

ANTHRISCUS CEREFOLIUM. De Cand. *Chærophyllum sativum.* Lam. *Scandix Cerefolium.* Linn. *Chervil.* An annual European plant, cultivated in gardens as a pot-herb, and supposed by some to possess remedial powers. It has a strong agreeable odour, especially when rubbed, and a pungent, slightly bitterish taste. These properties it owes to a volatile oil, which may be separated by distillation with water. It is said to be deobstruent, diuretic, and emmenagogue, and has been recommended by different authors in consumption, scrofula, dropsy, cutaneous and scorbutic affections, and as an external application to swollen breasts, bruises, and other local complaints or injuries. It is, however, very feeble, and is more used as an addition to broths than as a medicine. W.

ANTIMONIATED HYDROGEN. This is a gaseous substance, and, being taken by inhalation, is prepared at the moment of administration. A drachm of pure antimony and twice the quantity of pure zinc formed into an alloy, and a drachm of tartar emetic or chloride of antimony, are mixed, and introduced into a bottle with a large tubulure; and from time to time, as the gas is wanted for inhalation, from half a drachm to a drachm of muriatic acid is added, of which the whole quantity must not exceed about eight drachms. Muriatic acid gas is evolved at the same time with the antimoniated hydrogen; and to prevent the inhalation of the former, a sponge wet with an alkaline solution is made to close the respiratory orifices. This arrests the acid gas, but allows the other to pass into the lungs. The patient is to breathe the atmosphere impregnated in this manner for five minutes every hour. Besides, the bottle may be left unstopped in the mean time, so that the air of the chamber may become more or less affected. It is asserted that few therapeutical agents are more powerful than this in pneumonia and capillary bronchitis with fever. The gas is inodorous and unirritating, and the respiration is in no degree oppressed. The pulse diminishes in frequency and force, without nausea or vomiting; the expectoration is facilitated and increased; and a cure is effected more quickly than by any other known method of treatment. Such are the statements made by M. J. Hannon, an abstract of which may be seen in *Bouchardat's Annuaire* (1860, p. 143). A method of preparing pure antimoniated hydrogen, with the figure of an instrument used for that purpose, by Mr. W. L. Scott, will be found described in the *Med. Times and Gaz.* (Octob. 1865, p. 402). W.

ANTIRRHINUM LINARIA. Linn. *Linaria Vulgaris.* (Lindley.) *Common Toadflax.* This is a perennial herbaceous plant, from one to two feet high, with numerous narrow linear leaves, and a terminal crowded spike of large yellow flowers. It is a native of Europe, but has been introduced into this country, and now grows in great abundance along the road-sides, through the Middle States. It is readily distinguishable by the shape of its leaf, and its conspicuous yellow flowers, which appear in succession from June to October. The herb is the part used. It should be collected when in flower, dried quickly, and kept excluded from the air. When fresh it has a peculiar, heavy, rather disagreeable odour, which is in a great measure dissipated by drying. The taste is herbaceous, weakly saline, bitter, and slightly acrid. This plant is said to be diuretic and cathartic, and has been used in dropsy, jaundice, and cutaneous eruptions. It is most conveniently employed in infusion. The fresh plant is sometimes applied, in the shape of poultice or fomentation, to hemorrhoidal tumours; and an ointment made from the flowers has been employed for the same purpose, and also locally in diseases of the skin. The flowers are used in Germany for dyeing yellow. W.

AQUA BINELLI. An Italian nostrum, named after a physician of Turin, which at one time enjoyed great reputation in Europe as a styptic; but has been proved to possess very little efficacy. It is a transparent liquid, with little taste and an empyreumatic odour, and, after the discovery of creasote, was conjectured to contain a small proportion of that principle. It is now out of use. A recipe for its preparation is given in the *Annuaire de Thérapeutique*, 1848, p. 227. W.

AQUILEGIA VULGARIS. *Columbine.* A perennial herbaceous plant, indigenous in Europe, but cultivated in our gardens as an ornamental flower. All parts of it have been medicinally employed. The root, leaves, and flowers have a disagreeable odour, and a bitterish, acrid taste. The seeds are small, black, shining, inodorous, and of an oleaginous sweetish taste, followed by a sense of acrimony. Columbine has been considered diuretic, diaphoretic, and antiscorbutic, and has been employed in jaundice, in smallpox to promote the eruption, in scurvy, and externally as a vulnerary. It is not used at present, and is even suspected to possess dangerous properties, like most other Ranunculaceæ. W.

ARECA NUT. *Betel Nut.* This is the product of *Areca Catechu*, an East India tree belonging to the family of palms. The fruit, which is about the size and shape of a small egg, and of an orange-yellow colour, contains the nut embedded in a fibrous, fleshy en-

velope, and invested with a brittle shell which adheres to the exterior flesh. The kernel, which is the betel-nut of commerce, is of a roundish conical shape, rather larger than a chestnut, externally of a deep-brown diversified with a fawn colour, so as to present a reticular appearance, internally brownish-red with whitish veins, very hard, of a feeble odour when broken, and of an astringent, somewhat acrid taste. It abounds in tannin, and contains also gallic acid, a fixed oil, gum, a little volatile oil, lignin, and various saline substances. It yields its astringency to water; and, in some parts of Hindostan, an extract is prepared from it having the appearance and properties of catechu. Immense quantities of the nut are consumed in the East, mixed with the leaves of the Piper Betel, and with lime, forming the masticatory so well known by the name of *Betel*. The red colour which this mixture imparts to the saliva and the excrements is owing to the areca nut, which is also powerfully astringent, and, by its internal use, tends to counteract the relaxation of bowels to which the heat of the climate so strongly predisposes. The nut is used, in this country, almost exclusively in the preparation of tooth powder, for which purpose it is first reduced by heat to the state of charcoal. The superiority of this form of charcoal over that from other sources is probably owing to its hardness. The nut has been used successfully in Great Britain, by Dr. Edwin Morris, in the treatment of the tape-worm, in doses of from four to six drachms. (See *Am. Journ. of Med. Sci.*, April, 1862, p. 496.) W.

ARGEMONE MEXICANA. *Prickly Poppy.* An annual plant, belonging to the Papaveraceæ, growing in our Southern and Western States, Mexico, the West Indies, Brazil, and in many parts of Africa and Southern Asia. According to Dr. E. Bonavia, it grows abundantly about Lucknow, in Hindostan. (*Pharm. Journ.*, Nov. 1866, p. 297.) It has an erect, somewhat glaucous, bristly stem, with alternate sessile leaves, sinuated and prickly at the angles, and usually marked with white spots. The flowers are solitary, yellow or white, with two or three prickly deciduous sepals, four or six large petals, about twenty stamens, and four to six reflected stigmas. The whole plant abounds in a milky, viscid juice, which becomes yellow on exposure to the air. The plant was submitted to chemical examination by M. Charbonnier, who obtained from it a minute quantity of an alkaloid, which gave evidence to tests of being very similar to morphia, if not identical with it, as it is believed to be by its discoverer. (*Journ. de Pharm.*, Mai, 1868, p. 352.) From the statements of different authors, it may be inferred that the plant is emetic and purgative, and possesses also narcotic properties. The juice, which is acrid, has been used internally in obstinate cutaneous eruptions, and as a local application to warts and chancres, and in diseases of the eyes. The flowers are stated by De Candolle to have been employed as a soporific. But the seeds are most esteemed. They are small, round, black, and roughish. In the dose of two drachms, infused in a pint of water, they are said to act as an emetic. In smaller doses they are purgative. An oil may be obtained from them by expression, which has the cathartic property of the seeds, and, according to M. Lepine, might be advantageously used in the arts. (*Journ. de Pharm.*, Juillet, 1861, p. 16.) It may be separated by means of sulphuret of carbon, and, thus procured, it is described by M. Charbonnier as of a light-yellow colour, limpid, transparent, retaining its fluidity at 41° F., of a somewhat nauseous odour, and of a slightly acrid taste, which, however, are not disagreeable. It is a drying oil, and is entirely soluble in 5 or 6 measures of alcohol at 90°. It is thought applicable to various purposes in the arts, especially to painting; and the cultivation of the plant with a view to its production is suggested as a promising enterprise. M. Charbonnier found it gently cathartic in the dose of 15 to 25 drops, and emeto-cathartic in larger doses. (*Journ. de Pharm.*, Mai, 1868, p. 348.) According to Dr. W. Hamilton, the seeds unite an anodyne and soporific with the cathartic property; and, in the hands of Dr. Affleck, of Jamaica, have proved useful in flatulent colic, given in emulsion, in the dose of about eight grains, repeated every half hour till three doses were taken. The pain was relieved, and the bowels opened. (*Pharm. Journ.*, xiii. 642.) Dr. Bonavia also found it useful in colic with constipation, and, following a practice common in Upper India, applied it very successfully, as a local remedy, in a troublesome cutaneous affection about the waist, called the *dhad*, which is apt to occur in those regions. W.

ARSENIATE OF AMMONIA. *Ammoniæ Arsenias.* This salt is obtained in crystals by saturating a concentrated solution of arsenic acid with ammonia or carbonate of ammonia, and allowing it to evaporate spontaneously. It has been used with advantage by Biett in several inveterate diseases of the skin. It is administered in solution, formed by dissolving a grain of the salt in a fluidounce of distilled water. Of this the dose is from twenty to twenty-five drops, given in divided portions in the course of the day, and gradually increased. B.

ARSENIC ACID. *Acidum Arsenicum.* This acid is described at *page* 149. It has similar therapeutic effects to those of arsenious acid, but is more poisonous. The dose is the twentieth of a grain, given in aqueous solution. B.

ASARABACCA. This is the product of *Asarum Europæum*, an herbaceous perennial plant, growing in Europe, between 37° and 60° north latitude, in woods and shady places, and flowering in May. All parts of the plant are acrid. The leaves were specially directed by the London College, when the plant was recognised as officinal; but the whole plant,

including the root, stem, leaves, and flowers, is usually kept in the shops. The root is about as thick as a goose-quill, of a grayish colour, quadrangular, knotted and twisted, and sometimes furnished with radicles at each joint. It has a smell analogous to that of pepper, an acrid taste, and affords a grayish powder. The leaves, which have long footstalks, are kidney-shaped, entire, somewhat hairy, of a shining deep-green colour when fresh, nearly inodorous, with a taste slightly aromatic, bitter, acrid, and nauseous. Their powder is yellowish-green. Both parts rapidly lose their activity by keeping, and ultimately become inert. Geiger, however, asserts that they keep well if perfectly dry. Their virtues are imparted to alcohol and water, but are dissipated by decoction. According to MM. Feneulle and Lassaigne, the root contains a concrete volatile oil, a very acrid fixed oil, a yellow substance analogous to *cytisin*, starch, albumen, mucilage, citric acid, and saline matters. The latest analysis is by Gräger, who found in the *root* a liquid volatile oil, two concrete volatile substances called respectively *asarum camphor* or *asarone*, and *asarite*, a peculiar bitter principle called *asarin*, tannin, extractive, resin, starch, gluten, albumen, lignin, citric acid, and various salts; in the *leaves*, asarin, tannin, extractive, chlorophyll, albumen, citric acid, and lignin. The active principles appear to be the volatile oil, which is lighter than water, glutinous, yellow, of an acrid and burning taste, and a smell like that of valerian, and the asarin, which is soluble in alcohol and very bitter, and is probably the same as the *cytisin* of Feneulle and Lassaigne. (See *Cytisus Laburnum*, in *Part* III.) The root and leaves of asarabacca, either fresh or carefully dried, are powerfully emetic and cathartic, and were formerly much used in Europe with a view to these effects. The dose is from thirty grains to a drachm. But as an emetic they have been entirely superseded by ipecacuanha; and they are now used chiefly, if not exclusively, as an errhine. One or two grains of the powdered root, snuffed up the nostrils, produce much irritation, and a copious flow of mucus, which is said to continue sometimes for several days. The leaves are milder, and generally preferred. They should be used in the quantity of three or four grains, repeated every night until the desired effect is experienced. They have been strongly recommended in headache, chronic ophthalmia, and rheumatic and paralytic affections of the face, mouth, and throat; and are in great repute in Russia, as a remedy for the deranged state of health consequent on habits of intoxication. W.

ASCLEPIAS CURASSAVICA. *Bastard Ipecacuanha. Redhead. Blood Weed.* This is a pretty species of Asclepias, from one to three feet high, and bearing umbels of bright-red flowers. It is a native of the West Indies, abounding especially in Nevis and St. Kitts, where it is considerably used as a medicine. Both the root and expressed juice are emetic, the former in the dose of one or two scruples, the latter in that of a fluidounce or more. They are also cathartic in somewhat smaller doses; and the expressed juice, made into a syrup with sugar, has been strongly recommended as a remedy in worms. The medicine, however, is somewhat uncertain in its operation. According to Dr. W. Hamilton, the plant may also be usefully employed in arresting hemorrhages, and in obstinate gonorrhœa, in which it has been found very efficient by Dr. Barham. (See *Am. Journ. of Pharm.*, xix. 19.) W.

ASCLEPIAS INCARNATA. *Flesh-coloured Asclepias.* (*Gray's Manual*, p. 353.) This species of Asclepias held formerly a place in the secondary catalogue of the U. S. Pharmacopœia, from which, however, it was dismissed at the recent revision of that work. It has an erect downy stem, branched above, two or three feet high, and furnished with opposite, nearly sessile, lanceolate, somewhat downy leaves. The flowers are red, sweet-scented, and disposed in numerous crowded erect umbels, which are generally in pairs. The nectary is entire, with its horn exserted. In one variety the flowers are white. The plant grows in all parts of the United States, preferring a wet soil, and flowering from June to August. Upon being wounded it emits a milky juice. The root was the officinal portion. Its properties are probably similiar to those of *A. Syriaca;* but they have not, so far as we know, been fully tested. Dr. Griffith states that it has been employed by several physicians, who speak of it as a useful emetic and carthatic. (*Journ. of the Phil. Col. of Pharm.*, iv. 283.) Dr. Tully, of New Haven, has found it useful in catarrh, asthma, rheumatism, syphilis, and worms. W.

ASCLEPIAS SYRIACA. *A. Syriaca.* Willd. *Sp. Plant.* i. 1265. *A. Cornuti* (Decaisne, *Gray's Manual*, p. 351). *Common Silk-weed. Common Milk-weed.* This, like the preceding species, was discharged from the secondary catalogue of the U. S. Pharmacopœia, but, we think, on insufficient grounds, considering the extent to which it has been used by regular practitioners, to say nothing of its reputation with others. The silk-weed has simple stems, from three to five feet high, with opposite, lanceolate-oblong, petiolate leaves, downy on their under surface. The flowers are large, of a pale-purple colour, sweet-scented, and arranged in two or three nodding umbels. The nectary is bidentate. The pod or follicle is covered with sharp prickles, and contains a large quantity of silky seed-down, which has been used as a substitute for fur in the manufacture of hats, and for feathers in beds and pillows.

This species of Asclepias is very common in the United States, growing in sandy fields, on the road-sides, and on the banks of streams, from New England to Virginia. It flowers in July and August. Like the preceding species, it gives out a white juice when wounded, and has hence received the name of *milk-weed*, by which it is frequently called. This juice has a faint smell, a sub-acrid taste, and an acid reaction. According to Shultz, 80 parts of it contain 69 of water, 3·5 of a wax-like fatty matter, 5 of caoutchouc, 0·5 of gum, 1 of sugar with salts of acetic acid, and 1 of other salts. (*Pharm. Central Blatt*, 1844, p. 302.)

Dr. C. List has found the chief solid ingredient of the juice to be a peculiar crystalline substance, of a resinous character, closely allied to lactucone, and which he proposes to call *asclepione*. To obtain it, the juice is coagulated by heat, filtered so as to separate the liquid portion, and then digested with ether, which dissolves the asclepione, and yields it by evaporation. To purify it, the residue must be treated repeatedly with anhydrous ether, which leaves another substance undissolved. It is white, crystalline, tasteless, inodorous, fusible, insoluble in water and alcohol, soluble in ether, oil of turpentine, and concentrated acetic acid. A strong hot solution of potassa does not affect it. Its constituents are carbon, hydrogen, and oxygen, and its formula $C_{40}H_{34}O_6$. (List, *Liebig's Annalen*, Jan. 1849.)

Medical Properties and Uses. Dr. Richardson, of Massachusetts, found the root possessed of anodyne properties. He gave it with advantage to an asthmatic patient, and in a case of typhus fever attended with catarrh. In both instances it appeared to promote expectoration, and to relieve pain, cough, and dyspnœa. He gave a drachm of the powdered bark of the root, in divided doses, during the day, and employed it also in strong infusion. In a letter to one of the authors, dated Jan. 22d, 1850, Dr. A. E. Thomas, of Rocky Spring, Mississippi, stated that he had employed the root in scrofula with great success, and in dyspepsia with advantage. He found it cathartic and alterative, but observed no anodyne property. He was induced to try it by having noticed that it was much used by the planters in scrofula and other diseases, and by the recommendation of Dr. McLean, of Kentucky, who had employed it in scrofula for twenty years, with the most satisfactory results. In a letter subsequently received from Dr. McLean himself, this account of the virtues of the asclepias root has been confirmed. Dr. McLean has also found it an excellent alterative in hepatic affections; but he seems to be of the opinion that the root he employed was from a different species of asclepias, and one not described in this Dispensatory. Mention may here be made of another indigenous species of Asclepias, *A. verticillata* (*Gray's Manual*, p. 354), which has reputation in some parts of the Southern States as a remedy in snake-bites and the bites of venomous insects. It is given in the form of a saturated decoction of the fresh plant (root, stem, and leaves), of which three gills are said to have been taken at a draught, with the effect of producing an anodyne and sudorific effect, followed by a gentle sleep. (See *Va. Med. Journ.*, Dec. 1858, p. 458.) W.

ASPARAGUS OFFICINALIS. *Asparagus.* This well-known garden vegetable is a native of Europe. It is perennial and herbaceous. The *root*, which is inodorous, and of a weak, sweetish taste, was formerly used as a diuretic, aperient, and purifier of the blood; and it is stated to be still employed to a considerable extent in France. It is given in the form of decoction, made in the proportion of one or two ounces of the root to a quart of water. Hayne asserts that, in the dried state, it is wholly inert. The *young shoots* are much used as food. Before being boiled they have a disagreeable taste; and their juice was found by Robiquet and Vauquelin to contain a peculiar crystallizable principle, called *asparagin*. (See *page* 98.) This has been thought not to exert any special influence on the system; but Dr. Allen Dedrick, of New Orleans, has found it to be sedative to the circulation, eight grains of it having reduced his own pulse from 72 to 56 in the minute, while, at the same time, brief frontal headache, a sense of fulness of the eyes, and a feeling of muscular weakness were experienced. The effect on the pulse was perceived at the end of five minutes, was at its height in an hour, and continued so for half an hour, when it gradually subsided. The pulse was also rendered intermittent. (*N. O. Med. and Surg. Journ.*, xi. 198.) Asparagin is said to be obtained with facility by the process of dialysis. If the thick viscid mucilage of the marshmallow (*Althæa officinalis*) be put into a dialyser, with distilled water outside, the asparagin passes into the water, and may be obtained in crystals by evaporating the solution. (See *Pharm. Journ.*, May, 1862, p. 572.) It might probably be obtained in the same way from an infusion of asparagus.

The sprouts themselves are not without effect; as the urine acquires a disagreeable odour very soon after they have been eaten. They have been accused of producing irritation, with a morbid flow of mucus, of the urinary passages. (*Ann. de Thérap.*, 1861, p. 107.) They are considered by some writers as diuretic, aperient, and deobstruent, and as constituting a very wholesome and useful article of diet, early in the spring, when vegetables are scarce. Broussais thought that they were sedative to the heart, and recommended them especially in hypertrophy and other diseases of that organ attended with excessive action, and without phlogosis of the stomach. M. Gendrin, however, after much experience with asparagus, affirms that he never knew it to exercise the slightest influence over the heart, and ascribes its palliative effects, in diseases of that organ, to a diuretic action. He found it, in all the cases in which he administered it, to increase the quantity of urine, which, in some instances, was quintupled. The most convenient forms for exhibition are those of syrup and extract, prepared from the shoots. The former may be given in the dose of one or two fluidounces, the latter of half a drachm or a drachm. The syrup may be made by adding a sufficient quantity of sugar to the expressed juice of the shoots, previously deprived of its albumen by exposure to heat and by filtration; the extract, by evaporating the same juice to the consistence of a pilular mass. Dr. S. J. Jefferson, of England, has employed a tincture of asparagus for 16 years with great benefit, as an adjuvant of other diuretics. He prepares the tincture either by macerating 5 ounces of the dried tops in 2 pints of proof spirit; or

by taking 5 pounds of the fresh tops, expressing the juice, evaporating it to a pint, straining, and adding a pint of rectified spirit. He gives from half a drachm to two drachms with each dose of the diuretic employed. (*Am. Journ. of Med. Sci.*, N. S., xxx. 490; from the *Assoc. Med. Journ.*) The *berries* are capable of undergoing the vinous fermentation, and affording alcohol by distillation. In their unripe state they possess the same properties as the shoots, and probably in a much higher degree. We have employed a syrup prepared from them, with apparent advantage, in a case of diseased heart. The seeds have been tried as a substitute for coffee, which, when treated in the same way, they are said to resemble in flavour. (See *Boston Med. and Surg. Journ.*, July 19, 1854.) W.

ASPLENIUM FILIX FŒMINA. R. Brown. *Female Fern.* This is the *Polypodium Filix fœmina* of Linn., the *Aspidium Filix fœmina* of Swartz, and the *Athyrium Filix fœmina* of Roth. It has a root analogous in character to that of the male fern (*Aspidium Filix mas*), and has been supposed to possess similar vermifuge properties. At present, however, it is not used. The vulgar name of *female fern* is also given to the *Pteris aquilina*, or *common brake*, which is said by some authors to have the property of destroying the tapeworm. The leaves of two species of Asplenium, *A. Trichomanes*, or *common spleenwort*, and *A. Adiantum-nigrum*, or *black spleenwort*, are mucilaginous, and have been used as substitutes for the *maidenhairs* (*Adiantum Capillus Veneris* and *A. Pedatum*) as pectorals, though destitute of the aromatic flavour which is their chief recommendation. W.

ASTER PUNICEUS. (*Gray's Manual*, p. 195.) This species of Aster is a very common indigenous plant, growing from three to six feet high, in low swampy places. The rootlets are said to be aromatic, bitterish, and astringent, and have been employed in domestic and irregular practice as a stimulating diaphoretic, in rheumatic and catarrhal affections. Other species also of Aster have attracted attention for supposed remedial powers. W.

ATHEROSPERMA MOSCHATA. *Australian Sassafras.* The bark of this tree contains a volatile oil which is obtained by distillation, and has some reputation in Australia as a remedy. It is said to be diaphoretic, diuretic, and sedative to the heart. The dose is a drop every 6 or 8 hours. An alkaloid called *athero-spermin* has been extracted from the bark by M. Zeyer, of Munich. (*Pharm. Journ.*, April, 1863, p. 447.) W.

ATOMIZERS. *Pulverizers. Nebulizers.* These are instruments by which liquid substances, which cannot be wholly volatilized, as saline solutions for example, can be brought into a state of minute division, as in spray, whereby they may be introduced into the air-passages, and by inhalation into the lungs. Various soluble substances can thus be brought into contact with these surfaces in a diseased state, often with great advantage, which cannot otherwise be conveniently applied. The instruments are of various forms, but consist essentially of two tubes open at both ends, with a capillary opening at one end; and joined together so that they shall be perpendicular to each other with their capillary points in contact. One tube is perpendicular, and, when the instrument is in action, is inserted at its larger extremity into a vessel containing the liquid to be atomized; the other is horizontal. Through the latter a current of air is forced, which, on escaping at the capillary opening, carries with it a portion of the air in the orifice of the perpendicular tube, so that, to avoid a vacuum, the liquid is forced up by the atmospheric pressure, and mixes with the current of air as it escapes. It is thus minutely divided, and, accompanying the expanding current, may be received in the mouth or nostrils, and made to impinge on any part of these cavities or of the fauces, or be conveyed by inhalation into the lungs. The further consideration of this subject belongs rather to therapeutics than to pharmacology; and, for a description of different varieties of these instruments, the reader is referred to my work on the Practice of Medicine (6th ed., vol. i. p. 949), and to essays on the subject by Dr. J. M. Da Costa, Dr. J. Solis Cohen, both of Philadelphia, and by Dr. Ephraim Cutter, of Boston. For convenience of reference it may be proper to present here, in a tabular form, the most important substances used in this way, and the proportion to the fluid menstruum which each one should bear. For such a list I am indebted, in large part, to the essay of Dr. Da Costa above referred to. The number given opposite to each name represents the number of grains or of minims in which the substance named should be dissolved in a fluidounce of water.

Alum	10 to 30 grs.
Ammonia, muriate of	10 to 20 grs.
Arsenic (solution of arsenite of potassa)	1 to 20 mins.
Chloride of Sodium	5 to 20 grs.
Chlorinated Soda, solution of	30 to 60 mins.
Conium, fluid extract of	3 to 8 mins.
Copper, sulphate of	1 to 3 grs.
Hemp, tincture of	5 to 10 mins.
Hyoscyamus, fluid extract of	3 to 10 mins.
Iodine, compound solution of	2 to 15 mins.
Iron, perchloride of	⅛ to 2 grs.
Iron, solution of subsulphate of	8 to 16 mins.
Iron, sulphate of	1 to 2 grs.
Lead, acetate of	2 to 5 grs.
Lime-water	60 to 120 mins
Mercury, corrosive chloride of	¼ to 1 gr.
Morphia, solution of sulphate of	¼ to ½ gr.
Opium, tincture of	2 to 12 mins
" watery extract of	¼ to ½ gr.
Silver, nitrate of	1 to 10 grs.
Tannin	1 to 20 grs.
Tar-water	60 to 120 mins.
Turpentine, oil of	1 to 2 mins.
Zinc, sulphate of	1 to 6 grs.

In general a substance may be used in this way of the strength in which it would be applied to the mucous membranes. W.

BALM OF GILEAD. *Balsam of Gilead. Balsamum Gileadense. Baume de la Mecque.* Fr. The genuine balm of Gilead is the resinous juice of the *Amyris Gileadensis* of Linn., the *Balsamodendron Gileadense* of Kunth, a small evergreen tree, growing on the Asiatic and African shores of the Red Sea. It was in high repute with the ancients, and still retains its value in the estimation of the Eastern nations, among whom it is employed both as a medicine and cosmetic. In Western Europe and in this country, it is seldom found in a state of purity, and its use has been entirely abandoned. It is described as a turbid, whitish, thick, gray, odorous liquid, becoming solid by exposure. It possesses no medical properties which do not exist in other balsamic or terebinthinate juices. It was formerly known by the name of *opobalsamum;* while the dried twigs of the tree were called *xylobalsamum*, and the dried fruit, *carpobalsamum.* W.

BALSAM OF SULPHUR. This name was formerly given to a substance resulting from the reaction of sulphur upon olive oil at a high temperature. It was directed in the old Edinburgh Pharmacopœia, under the name of *Oleum Sulphuratum;* but was discharged at the last revision. The directions of the College were to boil *eight parts* of olive oil and *one part* of sublimed sulphur together, with a gentle fire, in a large iron pot, stirring them constantly till they united. The iron pot was directed to be large enough to hold three times the quantity of the materials employed; as the mixture might otherwise boil over. As the vapours which rose were apt to take fire, a lid was to be at hand to cover the pot, and thus extinguish the flame if necessary. Sulphur is soluble to a considerable extent in heated oil, from which, if the solution be saturated, it is deposited in a crystalline state on cooling. But it is not a mere solution which this process was intended to effect. The oil was partly decomposed, and the resulting preparation was an extremely fetid, acrid, viscid, reddish-brown fluid. In order that it might be obtained, it was necessary to heat the oil to the boiling point. *Sulphurated oil*, or *balsam of sulphur*, was formerly thought useful in chronic catarrh, consumption, and other pectoral complaints; but inconvenience arose from its acrid properties, and its internal use was abandoned. It is said to be sometimes applied as a stimulant to foul ulcers. The dose is from five to thirty drops. W.

BALSAMUM TRANQUILANS. *Baume Tranquille.* This is a preparation of some note, directed by the French Codex, and consisting essentially of olive oil holding in solution the active matters of certain narcotic and aromatic plants. The fresh plants are boiled with the oil until all their water is driven off; the oil is then expressed and poured upon the dried plants properly comminuted; and the mixture, having been allowed to stand for a month, is strained, and the oil decanted. The preparation is used by friction as an anodyne in local pains. A formula for it is contained in the *Am. Journ. of Pharm.* (Jan. 1862, p. 22), and in the *Journ. de Pharm.* (Août, 1862, p. 121). W.

BAPTISIA TINCTORIA. *Sophora tinctoria.* Linn. *Podalyria tinctoria.* Michaux. *Wild Indigo.* This is an indigenous perennial plant, found throughout the United States, growing abundantly in woods and dry barren uplands. It is from one to three feet high, with a smooth, very branching stem, small, ternate, cuneate-obovate, bluish-green leaves, and yellow flowers, which appear in July and August, and, like the whole plant, become black when dried. The root, which is the part most highly recommended, is of a dark-brown colour, of a slight peculiar odour in the dried state, and of a nauseous, bitter, somewhat acrid taste. Its virtues appear to reside chiefly in the cortical portion. Mr. B. L. Smedley has rendered it probable that it contains a peculiar alkaloid. (*Am. Journ. of Pharm.*, July, 1862, p. 311.) In large doses, it is said to operate violently as an emetic and cathartic; in smaller, to produce only a mild laxative effect. It is said to have proved useful in scarlatina, typhus fever, and in that state of system which attends gangrene or mortification. Dr. Thacher spoke highly of its efficacy as an external application to obstinate and painful ulcers; and Dr. Comstock, of Rhode Island, found it extremely useful, both as an internal and external remedy, in threatened or existing mortification. By the latter physician it was given in decoction, made in the proportion of an ounce of the root to a pint of water, of which half a fluidounce was administered every four or eight hours, any tendency to operate on the bowels being checked with laudanum. Dr. Stevens, of Ceres, Pennsylvania, has employed a decoction of the root advantageously in epidemic dysentery. (*N. Y. Journ. of Med.*, iv. 358.) It may be used externally in the form of decoction or cataplasm. The stem and leaves possess the same virtues as the root, though in a less degree. A pale-blue colouring substance has been prepared from the plant as a substitute for indigo, but is greatly inferior. Another species, *B. Alba*, or *prairie indigo*, which is abundant in our N. W. prairies, is said to have similar properties, and to be sometimes used as a substitute for *B. tinctoria.* W.

BARBADOES NUTS. *Purging Nuts. Physic Nuts.* These are the seeds of the *Curcas purgans* of Adanson (*Jatropha Curcas* of Linnæus), growing in Brazil, the West Indies, and on the western coast of Africa. The fruit is a three-celled capsule, containing one seed in each cell, and is about the size of a walnut. The seeds are blackish, oval, about eight lines long, flat on one side, convex on the other; and the two sides present a slight longitudinal prominence. They yielded to Soubeiran fixed oil, an acrid resin, sugar, gum, a fatty acid,

gluten, a free acid, and salts. The oil may be separated by expression. When fresh it is without smell or colour, but becomes yellowish and slightly odorous by time. When cold it deposits a white substance, which is probably margarin. Alcohol does not readily dissolve it. Some call it *jatropha oil*. For an account of the chemical properties of this oil, see the *Chemical Gazette* (Dec. 15, 1854, p. 469). From three to five of the *seeds*, slightly roasted and deprived of their envelope, operate actively as a cathartic, and not unfrequently produce nausea and vomiting, with a sense of burning in the stomach. The *oil* purges in the dose of twelve or fifteen drops, and is analogous in its action to croton oil, though less powerful. The cake left after the expression of the oil is an acrid emeto-cathartic, operating in the dose of a few grains. Either of these substances may produce serious consequences in overdoses. The leaves of the plants are rubefacient, and the juice is said to have been usefully employed as a local remedy in piles.

The seeds of *Curcas multifidus* (*Jatropha multifida*, Linn.) have similar properties, and yield a similar oil. This species also grows in Brazil and the West Indies. W.

BASSORA GUM. The plant which yields this substance is unknown. It came into commerce originally from the neighbourhood of Bassora, on the Gulf of Persia; but is often found mixed with gum brought from other countries, and is probably not the product of one plant exclusively. It is in irregular pieces, of various sizes, never very large, white or yellow, intermediate in the degree of its transparency between gum arabic and tragacanth, inodorous, tasteless, and possessed of the property of yielding a slight sound when broken under the teeth. But a small portion of it is soluble in water, whether hot or cold. The remainder swells up considerably, though less than tragacanth, and does not, like that substance, form a gelatinous mass, as it consists of independent granules which have little cohesion. The soluble portion is pure gum or *arabin*, and, according to M. Guérin, constitutes 11·2 per cent. The insoluble portion consists of a peculiar principle called *bassorin*, associated with a small proportion of saline substances, which yield, when the gum is burnt, 5·6 per cent. of ashes. The gum is useless both in medicine and pharmacy, and is described here only as containing a principle which enters into the composition of several medicinal substances.

Bassorin is insoluble in water, alcohol, and ether, but softens and swells up in hot or cold water. Diluted nitric and muriatic acids, with the aid of heat, dissolve it almost entirely. The acidulous solution, concentrated by evaporation, and treated with alcohol, lets fall a flocculent precipitate which has all the characters of pure gum, into which the bassorin appears to have been converted by the action of the acid. This does not, however, constitute more than a tenth part of the bassorin dissolved. By gradually evaporating the alcoholic acidulous solution, a thick, bitterish liquid is obtained, which exhales a strong odour of ammonia when treated with potassa. Strong nitric acid converts bassorin into mucic and oxalic acids; and, treated with sulphuric acid, it yields a sweet crystalline substance which is incapable of the vinous fermentation. (Guérin.) Vauquelin was the first to call attention to this principle, upon which he conferred its present name, from having first observed it in the Bassora gum. Bucholz afterwards discovered the same, or a closely analogous principle, in tragacanth; and John, a principle which was supposed to be the same in the gum of the cherry-tree. Hence it has sometimes been called *tragacanthin* and *cerasin*. M. Guérin, however, has demonstrated that the insoluble principle of the cherry gum is essentially different from bassorin. Berzelius considered the latter as belonging to the class of substances which he associated under the name of mucilage, and of which the mucilages of flaxseed and quince seed are examples. (See *Linum*, p. 528.) W.

BDELLIUM. This name has been given to two different gum-resins, distinguished as *Indian* and *African bdellium*. Dr. Royle was informed that the former was obtained from the *Amyris Commiphora* of Roxburgh, growing in India and Madagascar. The latter is said to be the product of *Heudelotia Africana*, which grows in Senegal. Bdellium sometimes comes mixed with gum arabic and gum senegal. It is either in small roundish pieces, of a reddish colour, semi-transparent, and brittle, with a wax-like fracture, or in large irregular lumps, of a dark brownish-red colour, less transparent, somewhat tenacious, and adhering to the teeth when chewed. It has an odour and taste like those of myrrh, but weaker. It is infusible and inflammable, diffusing while it burns a balsamic odour. According to Pelletier, it consists of 59 per cent. of resin, 9·2 of gum, 30·6 of bassorin, and 1·2 of volatile oil, including loss. In medical properties it is analogous to myrrh, and was formerly used for the same purposes; but it is now scarcely ever given internally. In Europe, it is still occasionally employed as an ingredient of plasters. The dose is from ten to forty grains. W.

BEDEGUAR. *Fungus Rosarum*. An excrescence upon the *sweetbriar* or *eglantine*, and other species of *Rosa*, produced by the puncture of insects, especially by one or more species of *Cynips*. It is of irregular shape, usually roundish, about an inch in diameter, with numerous cells internally, in each of which is the larva of an insect. It has little smell, and a slightly astringent taste. Though formerly considered diuretic, anthelmintic, and lithontriptic, and employed as a remedy for toothache, it has fallen into disuse. It was given in doses of from ten to forty grains. W.

BENZOATE OF SODA. *Sodæ Benzoas*. This salt has been employed by MM. Secquet and Bonjean, in conjunction with silicate of soda and other substances, as a remedy in

gout and rheumatism, for the purpose of eliminating uric acid. It is prepared by saturating a solution of benzoic acid with a solution of carbonate of soda. For the complicated formula proposed, including colchicum and aconite, see *Am. Journ. of Pharm.* (July, 1857, p. 314). B.

BENZOIN ODORIFERUM. Nees. *Laurus Benzoin.* Linn. *Spice-wood. Spice-bush. Fever-bush.* An indigenous shrub, from four to ten feet high, growing in moist, shady places, in all parts of the United States. Its flowers appear early in spring, long before the leaves, and are succeeded by small clusters of oval berries, which, when ripe, in the latter part of September, are of a shining crimson colour. All parts of the shrub have a spicy, agreeable flavour, which is strongest in the bark and berries. The small branches are sometimes used as a gently stimulating aromatic, in the form of infusion or decoction. They are said to be employed in this way by the country people as a vermifuge, and an agreeable drink in low fevers; and the bark has been used in intermittents. The berries, dried and powdered, were sometimes substituted, during the revolutionary war, for allspice. According to Dr. Drake, the oil of the berries is used as a stimulant. W.

BENZOLE. *Benzin. Benzene. Phene. Hydruret of Phenyl.* This substance must not be confounded with a commercial article sometimes sold as *benzine*, which is a mixture of various carbohydrogens of light sp. gr., obtained in the distillation of coal gas and petroleum. (See *Am. Journ. of Pharm.*, July, 1861, p. 367.) Benzole is a distinct carbohydrogen, with a definite constitution. It was originally obtained by distilling benzoic acid with lime. It was afterwards discovered by Faraday as a constituent of coal-gas tar. This tar, when distilled, furnishes *coal-naphtha* (the commercial benzine above referred to), a complex substance, containing a number of carbohydrogens, among which is benzole. Upon distilling this naphtha from a metallic still, surmounted by an open vessel filled with water, and containing a worm terminating in a refrigerated receiver, the benzole will pass over and condense in the receiver; while the other substances associated with it, having higher boiling points, will condense in the worm, and fall back into the still. The benzole is then purified by distillation at a heat between 176° and 194°, and by subjecting the product to a new distillation from one-fourth of its volume of sulphuric acid. A method of obtaining it pure is described by Mr. A. H. Church, consisting in the dry distillation of a compound made by treating the ordinary benzole of commerce with fuming sulphuric acid, then adding carbonate of ammonia, evaporating the whole to dryness, and exhausting the residue with alcohol. The alcoholic solution is distilled to dryness, and the remaining mass distilled at a higher heat. The distillate is washed with solution of potassa, and then rectified from caustic potassa. The product is perfectly pure benzole. (See *Am. Journ. of Pharm.*, March, 1860, p. 144.) M. E. Kopp purifies benzole by taking advantage of its high congealing point. He exposes the impure mixture containing it to a degree of cold sufficient to solidify it (5° F.), presses the congealed mass to separate the liquid carbohydrogens, allows it to become fluid, then again freezes and presses it, and thus obtains it almost entirely pure. The mixed fluids treated in this way he obtains by decomposing the heavier tar oils by a high degree of heat. (*Chem. News*, May 14, 1864, p. 229.)

Prof. Calvert, of Manchester, purifies coal-naphtha, so as to render it a sufficiently pure benzole to be usefully applied to the purpose of removing fatty and oily matters from animal and vegetable substances, by subjecting it to the action of sulphuric acid, added in small quantities, so long as coloration is produced, then washing it with pure water, and afterwards subjecting it to distillation in an ordinary still. The sulphuric acid destroys the less volatile carbohydrogens present, which interfere with the solvent power of the benzole.

In consequence of the great volatility and extreme inflammability of benzole and its attendant carbohydrogens, much care is necessary both in their preparation and subsequent use to avoid any possible exposure to flame. Very serious results have taken place from want of caution in this respect.

Benzole is a colourless oleaginous liquid, possessing an agreeable odour. Its sp. gr. is 0·85, congealing point 32°, and boiling point 176°. Its formula is $C_{12}H_6$. Its powers as a solvent are very extensive. Among the substances soluble in it are sulphur, phosphorus, and iodine. It dissolves quinia, but not cinchonia, with which it forms a bulky gelatinous mass. Morphia and strychnia are sparingly soluble. Its solvent power over some of the organic alkalies led Mr. John Williams, of London, to employ it in extracting them from the vegetables in which they are found; and he succeeded in obtaining them in several instances on a small scale. In this way he extracted quinia, quinidia, and amorphous quinia, together, from cinchona bark, but not cinchonia. In like manner he separated strychnia and brucia from nux vomica, and handsome crystals of cantharidin from cantharides. Mr. Williams supposes that benzole might form a good test of the value of Peruvian barks. Benzole is also a solvent of many of the resins, of mastic, camphor, wax, fatty and oily substances, essential oils, caoutchouc, and gutta-percha. The last two substances may be obtained, without alteration of properties, in tough sheets of any desired tenuity, by spreading their benzole solutions on glass or other polished surface, and allowing the solvent to evaporate. The same solutions, brushed over the skin, form artificial cuticles, which have been found useful as coverings to wounds and burns. The vapour of benzole,

when inhaled, acts as an anæsthetic. As benzole is often mixed, sometimes in but small proportion, with other hydrocarbons associated with it in coal tar and petroleum, it becomes desirable to be able to detect it in such an association. The following method, originating with M. Scharlommer, is based on the conversion of this carbohydrogen into anilin, and that into one of the characteristic colours derived from it. That part of the mixture which volatilizes at 150° C. (302° F.) is operated on. This is treated with fuming nitric acid, which, if benzole be present, gives rise to a nitrobenzole with its bitter-almond odour. The nitrobenzole is then converted by the action of granulated tin and muriatic acid into anilin, which is isolated by distilling the product with potassa. The anilin floats on the top of the liquid that passes. A little of this gives with hypochlorite of soda a fine purple colour; and a drop of it will yield the beautiful colour of rosanilin, if heated with a little bichloride of mercury. (*Journ. de Pharm.*, 4e sér., ii. 177.) In relation to benzole, see the paper of C. B. Mansfield, in the *Chem. Gaz.* (No. 159, p. 224), from which many of the facts of this article have been taken. A case is on record showing that, taken internally in a considerable quantity, it has a decided narcotic action, apparently intermediate between that of ardent spirit and opium. Swallowed accidentally, to the amount probably of one or two fluid-ounces, it produced vertigo with a sensation as of intoxication, followed by sleep for two hours, from which the patient awoke with a gay delirium, attended with bursts of laughter, and some impediment of speech, continuing for four hours. The pulse was slightly quickened, the surface warm, and the expression of face animated. Sleep then came on, from which the patient awoke next day, still feeling some dizziness. The breath had a strong smell of benzole. (See *Journ. de Pharm.*, Mars, 1861, p. 222.)

M. Reynal, of the Veterinary School at Alfort, has long been in the habit of destroying parasites in domestic animals by benzole, and proposes its employment in the parasitic diseases of man. It has the advantage of not affecting the skin. For this purpose a mixture may be used, consisting of 10 parts of benzole, 5 of soap, and 85 of water. B.

M. Dragendorff proposes further to utilize benzole by substituting it for amylic alcohol in the search for strychnia and brucia, which it dissolves more freely, without affecting the sense of smell so strongly. The sulphates of these alkaloids, however, are insoluble in benzole. (*Journ. de Pharm.*, 4e sér., v. 473.)

Prof. Moslor proposes benzole as a remedy in trichiniasis. It is among the most powerful anthelmintics, and will no doubt destroy all the trichinæ remaining in the alimentary canal; and there is hope that it may be able to follow the parasite fatally into the muscles. After some encouraging results with the lower animals, he tried it in several cases of the disease as it prevailed at Quedlinburg early in 1864. He gave the antidote in the following manner. Two drachms of benzole, and an ounce, each, of liquorice juice (solution of the extract) and mucilage of gum arabic, were mixed with four ounces of peppermint-water; and a tablespoonful of the mixture well shaken was given every hour or two. The medicine was easily taken and well borne; and many of the patients found themselves relieved under the treatment. Dr. Rudolff gave as much as two drachms daily, continued from four to six days. No bad effects showed themselves, even in cases when the fever was high. But the ultimate result is not stated. If necessary, larger doses of the medicine could probably be used without danger; at any rate, it would seem to be very promising as a prophylactic if taken soon after the ingestion of the infected meat. (*Bost. Med. and Surg. Journ.*, vol. lxxi. p. 381.) W.

Nitrobenzole. Benzole, by the action of fuming nitric acid, is converted into *nitrobenzole*, also called *nitrobenzule* and *nitrobenzide*, having the formula $C_{12}H_5.NO_4$. The product, after having been washed with water, forms an oily, yellowish, intensely sweet liquid, with an odour like that of oil of bitter almonds. Its density is 1·209, and boiling point 415°. Latterly it has become of commercial importance under the name of *artificial oil of bitter almonds*, being employed in confectionery, for scenting soaps, and for flavouring articles of diet. Nitrobenzole may be viewed as benzole, in which one eq. of hydrogen is replaced by one of hyponitric acid. For some observations on nitrobenzole, especially for a test of it by Mr. Maisch, see *Part* I. page 573. Dr. F. Mahla, of Chicago, considers the commercial nitrobenzole as a different compound from the proper chemical article, which he has found to have an odour between that of cinnamon and of bitter almond oils, but more closely analogous to the former. (*Am. Journ. of Pharm.*, May, 1859, p. 202.) B.

A very interesting paper by Mr. H. Letheby, on the physiological and toxicological properties of nitrobenzole, is contained in the *Pharmaceutical Journal* (Sept. 1863, p. 130). In manufactories, where the fluid is prepared, the workmen are often affected with headache and sleepiness from exposure to the vapour which escapes; but the effects are quickly relieved by fresh air and a mild stimulant. Two fatal cases are, however, recorded, one from the inhalation of the vapour, proceeding from the poison spilled upon the person of the individual affected, the other from the accidental swallowing of a small portion. The effects were the same. For some time there was no feeling of discomfort; but gradually symptoms of stupor came on, with flushed face, ending in profound coma, in which state the patients died, about 9 hours from the time of taking the poison, the coma having come on in 4 hours. The brain was found congested, the heart full, and the blood black and fluid.

Chemical examination detected both nitrobenzole and anilin in the blood, showing that the former had been converted into the latter. Mr. Letheby also made experiments with the poison on domestic animals, and obtained some extraordinary results. From 30 to 60 drops were given by the mouth to cats and dogs. There was rarely vomiting or other sign of gastric irritation. Two classes of effects were observed, either rapid coma, or a slow occurrence of palsy and coma after a period of apparent inaction of the poison. Even in the rapidly comatose cases, paralytic symptoms were noticed in the earlier stage. The time varied in these cases from 25 minutes to 12 hours between the exhibition of the poison and death. In the slower cases there was no visible effect for hours and sometimes for days. Suddenly, however, the animal would be attacked with vomiting, followed by convulsions, which, on their subsidence, left more or less paralysis, first of the hinder and then of the fore limbs. After this the animal generally lay for days, more or less conscious, with now and then epileptic attacks, and at length died of exhaustion or gradually recovered. The time from the exhibition of the poison to the first epileptic fit was from 19 to 72 hours, in most cases about two days, and to the period of death was from 4 to 9 days. This apparent inaction of the poison at first is very extraordinary, almost justifying the belief in those cases of poisoning said to have occurred in ancient times, in which the substance given exerted no effect till a considerable time after it was exhibited. The explanation is that the nitrobenzole undergoes changes in the system into a more violent poison, and as anilin is found after death, this may be the real agent.

Notwithstanding these statements of Mr. Letheby, we find it positively asserted by M. Collas that nitrobenzole is not poisonous; as M. Lassaigne had made numerous trials with it on dogs, to which he had given from one to two drachms without other effect than to perfume their evacuations. (*Ann. de Thérap.*, 1861, p. 35.) It is obvious that either the substances with which Mr. Letheby and M. Lassaigne experimented were not the same; or that the causes which in some of Mr. Letheby's cases operated to prevent action for a time, were of permanent operation in the cases of M. Lassaigne. W.

BETONICA OFFICINALIS. *Wood Betony.* A perennial European herb, belonging to the labiate plants. It has a pleasant but feeble odour, and a warm, somewhat astringent, and bitterish taste. By the ancients it was much esteemed, and employed in numerous diseases; but it is at present little used. It is slightly warming and corroborant, but is inferior in this respect to many other plants of the same family. The root has been considered emetic and purgative. W.

BETULA ALBA. *Common European Birch.* Various parts of this tree have been applied to medical uses. The young shoots and leaves secrete a resinous substance, having acid properties, which, combined with soda, is said to produce the effects of a tonic laxative. (*Journ. de Pharm.*, xxvi. 208.) The *inner bark*, which is bitterish and astringent, has been employed in intermittent fever. The epidermis is separable into thin layers, which may be employed as a substitute for paper, and are applied to various economical uses. The bark contains a peculiar principle, called *betulin*, which is ranked among the subresins. When the bark is distilled, it yields an empyreumatic oil, having the peculiar odour of Russia leather, in the preparation of which it is employed. This oil has been found very useful as a local application in chronic eczema. The *leaves*, which have a peculiar, aromatic, agreeable odour, and a bitter taste, have been employed, in the form of infusion, in gout, rheumatism, dropsy, and cutaneous diseases. The same complaints, particularly dropsy, are said to have been successfully treated by enveloping the body in the fresh leaves, which thus applied excite perspiration. When the stem of the tree is wounded, a saccharine *juice* flows out, which is considered useful in complaints of the kidneys and bladder, and is susceptible, with yeast, of the vinous fermentation. A beer, wine, spirit, and vinegar are prepared from it, and used in some parts of Europe.

Of the American species of birch, *Betula lenta*, variously called *sweet birch*, *black birch*, *cherry birch*, and *mountain mahogany*, is remarkable for the aromatic flavour of its bark and leaves, which have the odour and taste of Gaultheria procumbens, and are sometimes used in infusion, as an agreeable, gently stimulant, and diaphoretic drink. An oil is obtained by distillation from the bark, which has been proved by Prof. Procter to be identical with oil of gaultheria. As in the case of the oil of bitter almonds, this oil does not pre-exist in the dried bark of the birch, but is formed by reaction between water and a neuter principle in the bark, analogous to amygdalin, to which Prof. Procter has given the name of *gaultherin*. (*Am. Journ. of Pharm.*, xv. 243 and 246.) This species also affords a saccharine liquor, which, indeed, appears to be common to all the birches. The bark of *B. papyracea* is employed by the Northern Indians for making canoes; and thin layers of the epidermis are placed inside of boots to prevent the access of moisture. W.

BEZOAR. This name has been given to concretions formed in the stomach or intestines of animals, which were formerly thought to possess extraordinary medical virtues. Many varieties have been noticed; but they were all arranged in two classes, the *oriental bezoar* (*lapis bezoar orientalis*), and *western bezoar* (*lapis bezoar occidentalis*), of which the former was most esteemed. They have fallen into merited neglect. W.

BICARBONATE OF AMMONIA. This salt has been brought into notice by Prof.

Wm. Procter, in reference to its antacid properties. It is formed by exposure of the ordinary carbonate to the air, and is found in considerable quantities on the sides of casks in which that salt is imported, and less largely even in the bottles in which it is kept in the shops. The ordinary carbonate of ammonia, being in fact a sesquicarbonate, undergoes this change by giving off an equivalent of the monocarbonate. When pure, the bicarbonate of ammonia is white, having the same crystalline form as the bicarbonate of potassa, of a saline slightly ammoniacal taste, and a feeble odour of ammonia, ascribable to a very slow volatilization. On exposure to heat, it gives off carbonic acid. It is soluble in 8 parts of water at 60°, is nearly insoluble in officinal alcohol, but soluble in diluted alcohol; and its solution has an alkaline reaction with syrup of violets. It may be prepared by treating sesquicarbonate of ammonia with officinal alcohol, whereby the monocarbonate is dissolved, and the bicarbonate left To render this still purer it should be washed with alcohol and dried. It is obtained as a crystalline precipitate by adding alcohol to a saturated solution of the ordinary carbonate; or by passing carbonic acid through the same solution. It may be used as an antacid in the same manner and the same doses as bicarbonate of soda, being preferable to that salt when a slightly stimulant impression on the stomach is desired. It is due to Prof. Procter to state that this article has been taken, simply with verbal alteration, from his communication on the subject to the *Am. Journ. of Pharm.* (July, 1869, p. 294). W.

BIDENS BIPINNATA. (*Gray's Manual*, p. 222.) *Spanish Needles.* An herbaceous indigenous plant, of which the root and seeds, as well as those of other species of the same genus, have a popular reputation as emmenagogue, and are given by the "eclectics" in laryngeal and bronchial diseases as expectorants. W.

BIRD-LIME. A viscid substance, existing in various plants, particularly in the bark of *Viscum album* and *Ilex aquifolium* or European holly, from the latter of which it is usually procured. The process for preparing it consists in boiling the middle bark for some hours in water, then separating it from the liquid, and placing it in proper vessels in a cool situation, where it is allowed to remain till it becomes viscous. It is then washed to separate impurities, and constitutes the substance in question. Bird-lime thus prepared is greenish, tenacious, glutinous, bitterish, and of an odour analogous to that of flaxseed oil. Exposed to the air in thin layers it becomes dry, brown, and pulverizable, but reacquires its viscidity upon the addition of water. It is a complex body, but is thought to owe its characteristic properties to a proximate principle, identical with that which exudes spontaneously from certain plants, and is called *glu* by the French chemists. This principle is without odour or taste, extremely adhesive, fusible by heat, inflammable, insoluble in water, nearly insoluble in alcohol, but dissolved freely by ether and oil of turpentine. According to M. Macaire, it is insoluble in the fixed oils, either hot or cold; a property which distinguishes it from the resins. M. Macaire proposes for it the name of *viscin*. (*Journ. de Pharm.*, xx. 18.) Bird-lime is so tenacious that it may be employed to catch small birds, which, when they alight on a stick thickly covered with it, are unable to escape. W.

BISTORT. This is the root of *Polygonum Bistorta*, a perennial herbaceous plant, growing in Europe and the North of Asia. The root is cylindrical, somewhat flattened, about as thick as the little finger, marked with annular or transverse wrinkles, furnished with numerous fibres, and folded or bent upon itself, so as to give it the tortuous appearance from which its name was derived. When dried, it is solid, brittle, of a deep-brown colour externally, reddish within, inodorous, and of a rough, astringent taste. It contains much tannin, some gallic acid and gum, and a large proportion of starch. It resembles the other vegetable astringents in medical properties, and is applicable to the same complaints; but is less efficient than catechu or kino, and in this country is seldom used. It may be employed in powder, decoction, or extract. The dose of the powder is 20 or 30 grains.

Besides the bistort, some other plants belonging to the genus Polygonum have been used as medicines. Among those are *P. aviculare*, or *knot grass*, a mild astringent, formerly employed as a vulnerary and styptic; *P. Persicaria* (Persicaria mitis), of a feebly astringent saline taste, and at one time considered antiseptic; and *P. Hydropiper* or water-pepper (Persicaria urens), the leaves of which have a burning and biting taste, inflame the skin when rubbed upon it, and are esteemed diuretic. The *water-pepper* or *smart-weed* of this country—*P. punctatum* (Elliott), *P. hydropiperoides* (Michaux)—which grows abundantly in moist places, possesses properties similar to those of the European water-pepper, and is occasionally used as a detergent in chronic ulcers, and internally in gravel. Dr. Eberle very strongly recommended it in amenorrhœa, in which complaint he found no other remedy equally effectual. He gave a fluidrachm of the saturated tincture of the plant, or from four to six grains of the extract, three or four times a day. He found it to produce a warmth and peculiar tingling sensation throughout the system, with slight aching pains in the hips and loins, and a sense of weight and tension within the pelvis. (*Eberle's Mat. Med.*, 4th ed., i. 441.) Dr. Wilcox, of Elmira, New York, has found advantage from a decoction of the dried leaves, made in the proportion of an ounce to the pint, and applied locally, in mercurial salivation,

and the sore-mouth of nursing women. (*Am. Journ. of Med. Sci.*, N.S., xvi. 248.) *P. Fagopyrum* is common *buckwheat*. The leaves of this plant have been found by Mr. Ed. Schunck to contain a crystallizable colouring principle, identical with the *rutin* or *rutic acid* previously discovered by Weiss in the leaves of the common rue, and probably with the *ilixanthin* of Moldenhaus, existing in the leaves of Ilex aquifolium or common holly. Buckwheat leaves yielded to Mr. Schunck somewhat more than one part of rutin in a thousand. (*Chem. Gaz.*, No. 399, p. 201.) W.

BISULPHATE OF POTASSA. *Potassæ Bisulphas.* This salt, though formerly officinal in the Ed. and Dub. Pharmacopœias, has been omitted in the British. The following are the formulas of the two Colleges. "Take of the residuum of the preparation of pure Nitric Acid *two pounds;* Sulphuric Acid (commercial) *seven fluidounces and one fluidrachm* [Imperial meas.]; boiling Water *six pints* [Imp. meas.]. Dissolve the salt in the Water, add the Acid, concentrate the solution, and set it aside to cool and form crystals." (*Ed.*) "Take of Sulphate of Potash, in powder, *three ounces* [avoirdupois]; Pure Sulphuric Acid *one fluidounce* [Imperial measure]. Place the Acid and Salt in a small porcelain capsule, and to this apply a heat capable of liquefying its contents, and which should be continued until acid vapours cease to be given off. The Bisulphate, which concretes as it cools, should be reduced to a fine powder, and preserved in a well-stopped bottle." (*Dub.*)

In explaining the Edinburgh formula, it is only necessary to recall to the reader's attention a part of the explanations given under the head of *Acidum Nitricum*, in *Part* I. It is there stated that, for the decomposition of nitre on the small scale for the purpose of obtaining nitric acid, it is necessary to use two eqs. of sulphuric acid to one of the salt. Consequently, the salt which remains after the distillation of nitric acid is really a bisulphate, and would seem only to require to be dissolved, and the solution filtered and duly evaporated, in order to obtain the salts in crystals. But Mr. Phillips states that, when bisulphate of potassa is dissolved in water, and the solution is allowed to crystallize, some sulphate and much sesquisulphate are obtained instead of bisulphate, owing to the water retaining a part of the excess of acid in solution. This result is prevented by the sulphuric acid directed to be added, and, consequently, the real bisulphate is obtained in crystals. In the *Dublin* process, sulphate of potassa is mixed with more sulphuric acid than is necessary to convert it into bisulphate, and the mixture is exposed to a liquefying heat, which is continued so long as acid vapours are given off. The portion of acid, more than sufficient to form a bisulphate, is thus driven off; so that the saline matter left is the salt under consideration, which, after concreting, is reduced to fine powder.

Properties, &c. Bisulphate of potassa is a white salt, having the form of a right rhombic prism, so flattened as to be tabular, and a bitter and extremely acid taste. It is soluble in twice its weight of cold, and in less than its weight of boiling water. Alcohol does not dissolve it, but, when added to an aqueous solution, precipitates the neutral sulphate. Exposed to the air, it effloresces slightly on the surface, and when moderately heated readily melts, and runs like oil. At a red heat it loses water and the excess of acid, and is reduced to the neutral sulphate. From its excess of acid, it acts precisely as an acid on the carbonates, causing them to effervesce. It is incompatible with alkalies, earths, and their carbonates, with many of the metals, and most oxides. This salt was formerly called *sal enixum*. It consists of two eqs. of sulphuric acid 80, one of potassa 47·2, and two of water 18 = 145·2.

Medical Properties and Uses. Bisulphate of potassa unites the properties of an aperient and tonic, and may be given in constipation with languid appetite, such as often occurs in convalescence. Dr. Paris states that it forms a grateful adjunct to rhubarb. It answers, also, according to Dr. Barker, for preparing an aperient effervescing draught at little expense. Equal weights, a drachm for instance, of the bisulphate and of carbonate of soda, may be dissolved separately, each in two fluidounces of water, then mixed, and taken in the state of effervescence. The dose of the bisulphate is one or two drachms. B.

BISULPHURET OF CARBON. *Bisulphide of Carbon. Sulphuret of Carbon. Sulphide of Carbon. Carburet of Sulphur.* This compound is formed by passing the vapour of sulphur over charcoal, heated to redness in a porcelain tube. Prepared on the large scale, the charcoal may be heated in a cast-iron cylinder, as recommended by M. Chandelon. According to M. Millon, it is purified by first washing it repeatedly in distilled water, then putting it upon quicklime in a large retort, and, after a contact of 24 hours, distilling it from the lime. The vapours are received in a vessel containing a large quantity of pure copper turnings. It is a transparent, colourless, exceedingly volatile liquid, having a pungent, somewhat aromatic taste, and, as found in commerce, a very fetid smell. But, when purified in the manner above directed, if not perhaps very agreeable to the smell, it is much less disagreeable than as ordinarily found, and is employed by MM. Millon and Commaile for extracting the sweetest perfume of flowers. (*Journ. de Pharm.*, Nov. 1868, p. 361.) On exposure to sunlight for a considerable time, it becomes somewhat yellow, owing to a partial decomposition; and traces of formic acid and sesquisulphide of carbon have been noticed in the results. (O. Loew, *Am. Journ. of Sci.*, Nov. 1868.) Its

sp. gr. is 1·272. In composition it is a bisulphuret. Taken internally, it acts as a diffusible stimulant, accelerating the pulse, augmenting the animal heat, and exciting the secretions of the skin, kidneys, and genital organs. It has been employed in obstinate rheumatic and arthritic affections, paralysis, and cutaneous eruptions, and more recently as a resolvent in indolent tumours. It is used both internally and externally. For exhibition in gout and rheumatism, Dr. Otto, of Copenhagen, employed an alcoholic solution, in the proportion of two drachms to the fluidounce, of which four drops were given every two hours. At the same time the affected parts were rubbed with a liniment, made by dissolving the bisulphuret in the same proportion in olive oil. Dr. Krymer applied it successfully to an indolent tumour by allowing forty or fifty drops to fall upon it three times a day. In this case it may be supposed to have acted by the cold produced. He also succeeded in reducing several strangulated hernias, by applying some drops of the bisulphuret to the hernial tumour. Dr. Turnbull found the vapour useful in the resolution of indurated lymphatic glands. It is applied by means of a bottle with a proper sized mouth, containing a fluidrachm of the bisulphuret, imbibed by a piece of sponge. The skin over the gland is first well moistened with water. He employed the vapour also with benefit in deafness, when dependent on want of nervous energy, and a deficiency of wax. For this purpose, the bottle containing the bisulphuret is made with a neck to fit the meatus, and, being applied to the ear, is held there until considerable warmth is produced. Dr. Geo. Kennion, of Harrogate, has employed it in a similar manner with happy effect, in nervous headache, the mouth of the bottle being previously applied to the temple or behind the ear. (*Bost. Med. & Surg. Journ.*, Oct. 1, 1868, p. 143; from the *British Med. Journ.*) Dr. C. G. Page, of Boston, has used the vapour with advantage for the alleviation of local pains. Mr. James Schiel, of St. Louis, Mo., recommends the bisulphuret, mixed with an equal measure of alcohol, in neuralgia of the face, toothache, and similar affections. The mixture, poured upon some raw cotton, is to be rubbed vigorously on the part affected for five or six seconds. (*St. Louis Med. and Surg. Journ.*, Jan. 1857.)

Bisulphuret of carbon possesses diversified solvent powers, and is extensively used in the arts, the demand for it having made it a cheap product. Mr. Alexander Parkes, of Birmingham, claims the credit of having first produced it largely for manufacturing purposes. (*Chem. News*, June 21, 1867, p. 321.) Among other substances, it readily dissolves sulphur, phosphorus, bromine, and iodine. The solution of phosphorus is a powerful deoxidizing agent. (*Journ. de Pharm.*, 4e sér., iv. 464.) According to M. A. Vogel, it dissolves eighteen times its weight of phosphorus without losing its fluidity. (*Ibid.*, Mars, 1869, p. 237.) It has been proposed by M. Lepage, of Gisors, for extracting the fixed oils of nutmegs, bay berries, and croton seeds. M. Deiss, of Paris, employs it for extracting the fat of bones. (See *page* 655.) In India-rubber manufactories, it is used as a solvent of the caoutchouc. The extensive employment of it in this way has shown that air, loaded with its vapour, is poisonous. According to M. Delpech, the workmen exposed to the fumes of the bisulphuret are affected with headache, vertigo, and over-excitement of the nervous system, as evinced by voluble talking, incoherent singing, or immoderate laughter, or sometimes by weeping; and a continuance of the exposure is apt to cause at length a state of cachexia, characterized by general weakness, loss of sexual appetite, dulness of sight and hearing, and impairment of the memory. M. S. Cloëz has made with it experiments on some of the smaller animals, as rats and rabbits, which were confined under a bell-glass with some cotton saturated with the bisulphuret. In a few moments the animal exhibited signs of its action in great excitement, followed by retarded movements, with some convulsive shocks, then fell on its side and died in five minutes from the beginning. Congestion of the lungs and of the cavities of the heart, without any cerebral lesion, while the right auricle continued to contract two hours after apparent death, were the phenomena observed on dissection. (*Lancet*, Sept. 1866, p. 267.)

Protosulphuret of carbon (CS) was discovered in May, 1857, by M. E. Baudrimont, of Paris. It is conveniently obtained by passing the vapour of the bisulphuret over spongy platinum or over pumice heated to redness. It is a colourless gas, a little heavier than carbonic acid, having an odour like that of the bisulphuret. It burns with a blue flame, producing carbonic acid, sulphurous acid, and sulphur. By water it is decomposed, so as to form carbonic oxide and sulphuretted hydrogen. When breathed it appears to act as an anæsthetic. B.

BITTERA FEBRIFUGA. *Bitter Ash.* The name *Byttera febrifuga* was given by M. Bélanger to a tree growing in Martinico, in the West Indies, the wood of which has tonic properties closely analogous to those of quassia. It appears to be one of the Simarubaceæ; but differs from the plants of the genus Simaruba of De Candolle, in having hermaphrodite flowers, resembling in this respect the Quassia of that author. A bitter principle has been separated from the wood by M. Gerardias, which is closely analogous if not identical with quassin, the active principle of quassia. The wood has long been used in the West Indies in the cure of intermittents, and probably has all the remedial properties of the simple bitters. (*Journ. de Pharm.*, xxxi. 110.) It seems, however, at present to be admitted that this Byttera of M. Bélanger is really the Quassia excelsa of Linn., the Simaruba excelsa of De Candolle, from which quassia is generally obtained (*Ann. de Thérap.*, 1858, p. 190); and a specimen of the wood of this supposed Byttera, said to be from the Island of

Guadeloupe or Martinique, which the author had an opportunity of seeing at the Palais d'Industrie in Paris, certainly bore a very close resemblance to the billets of quassia. W.

BOLE ARMENIAN. The term *bolus* or *bole* was formerly applied to various forms of argillaceous earth, differing in colour, or place of origin. Such were the *Armenian*, *Lemnian*, and *French boles*, and the *red* and *white boles*. Some of these substances were so highly valued as to be formed into small masses and impressed with a seal, and hence received the name of *terræ sigillatæ*. They were all similar in effect, though the small proportion of oxide of iron contained in the coloured boles may have given them greater activity. The only one at present kept in the shops is that called *bole Armenian*, from its resemblance to the substance originally brought from Armenia. It is prepared, by trituration and elutriation, from certain native earths existing in different parts of Europe. It is in pieces of various sizes, reddish, soft, and unctuous, adhesive to the tongue, and capable of forming a paste with water. It consists chiefly of alumina and silica, coloured with oxide of iron. The boles were formerly employed as absorbents and astringents, and were undoubtedly useful in some cases of acidity of the stomach and relaxed bowels Bole Armenian is used chiefly as a colouring ingredient in tooth powders. W.

BORAGO OFFICINALIS. *Borage.* This is an annual, hairy, succulent European plant, one or two feet high, with fine blue flowers, on account of which it is sometimes cultivated in our gardens. All parts of it abound in mucilage, and the stem and leaves contain nitrate of potassa with other salts. To these constituents the plant owes all its virtues. It is much used in France. An infusion of the leaves and flowers, sweetened with honey or syrup, is employed as a demulcent, refrigerant, and gently diaphoretic drink in catarrhal affections, rheumatism, diseases of the skin, &c. The expressed juice of the stem and leaves is also given in the dose of from two to four ounces. The flowers are sometimes applied externally as an emollient. A distilled water, extract, and syrup were formerly used, but have fallen into neglect. Borage is scarcely known in this country as a medicinal plant. W.

BORATE OF AMMONIA. *Biborate of Ammonia.* By dissolving boracic acid in excess in heated water of ammonia, and allowing the solution to cool slowly, biborate of ammonia is obtained in crystals. These are rhombic octahedrons, with truncated summits, and often truncated edges, and are semitransparent. The taste of the salt is alkaline, and it has an alkaline reaction. On exposure, it effloresces, losing ammonia, and becoming in time the quadriborate. It is soluble in about twelve parts of water. (*Gmelin*, ii. 435.) Attention has recently been called to this salt by M. Beeker, who has used it in cases of stone in the bladder and renal colic, and, as he believes, almost constantly with an amelioration of the symptoms. Under its influence the urine becomes loaded with uric acid and the earthy phosphates. It is said also to be an excellent remedy in chronic catarrh of the bladder. It is believed by M. Beeker to be the *ludus* of Paracelsus, which had a great reputation in the treatment of urinary calculi. It may be given in the dose of from 10 to 20 grains every hour, in water sweetened with liquorice. (*Ann. de Thérap.*, 1867, p. 94; from *Journ. de Thérap. Med.-chir.*, Sept. 1, 1866.) W.

BRAZIL NUTS. *Cream Nuts.* These are edible nuts imported from Brazil, and sometimes employed in making cream syrups for giving flavour to carbonic acid water. In Brazil an expressed oil is obtained from them, which is said to be used for burning, making ointments, and adulterating copaiba. Dr. Edward Donnelly, of Philadelphia, states, in a communication to the American Pharmaceutical Association (*Proceedings*, 1858, p. 327), that the nuts are the product of the *Bertholletia excelsa* (Humboldt and Bonpland), a large and beautiful tree, growing over extensive regions in South America. The leaf and fruit are figured in the work just referred to. W.

BRAZIL WOOD. A red dye-wood, the product of different species of Cæsalpina, growing in the West Indies and South America. Two varieties are known in commerce:—1. The proper Brazil wood, said to be derived from *Cæsalpina echinata*, and sometimes called *Pernambuco* or *Fernambuco wood*, from the province of Brazil where it is collected; 2. the *brasiletto*, produced by *C. Brasiliensis* and *C. Crista*, which grow in Jamaica and other parts of the West Indies. The former is the most highly valued. The *sappan* or *sampfen wood* may be referred to the same head, being obtained from the *Cæsalpina Sappan*, and possessing properties analogous to those of the brasiletto. The *Nicaragua* or *peach wood* is also analogous to the brasiletto, and is said by Bancroft to be derived from a species of Cæsalpina. It is produced in the East Indies. Brazil wood is nearly inodorous, has a slightly sweetish taste, stains the saliva red, and imparts its colouring matter to water. It was formerly used in medicine; but has been abandoned as inert. In pharmacy it serves to colour tinctures, &c.; but its chief use is in dyeing. A red lake is prepared from it, and it is an ingredient in a red ink. Its dyeing properties are owing to a crystallizable colouring principle, named *breselin* or *brasilin*. This is of a sulphur-yellow colour, which it preserves in the dark, but soon loses in the sunlight, to which it is remarkably sensitive, changing to a reddish hue after a few minutes' exposure, and undergoing a similar alteration in diffused daylight, though more slowly. The principle should, therefore, be kept in perfectly opaque vessels. It is sparingly soluble in water, yielding a sweet and almost colourless solution which is not changed by acids, but is deeply reddened by alkalies. In alcohol and ether it is somewhat more soluble than in water, giving a light-yellow solution. The colourless

watery solution soon becomes reddish in the air, afterwards yellowish-red, in which condition the solution acquires the curious property of phosphorescing in a golden-yellow light. (C. F. Schönbein, *Neues Repertor.*, A. D. 1868, vol. xvii., part vii., p. 390.) W.

BROMIDE OF IRON. *Ferri Bromidum.* This bromide is obtained by heating gently, in thirty parts of water, two parts of bromine, and one of iron filings. When the liquid has become greenish, it is filtered and evaporated to dryness in an iron vessel; and the dry mass, again dissolved and evaporated to dryness, furnishes the bromide. Bromide of iron is a brick-red, deliquescent salt, very soluble, and extremely styptic. For medical employment it should be in aqueous solution, protected by sugar. Mr. Dillwyn Parrish has proposed the following formula. Take of bromine *two hundred grains;* iron filings *eighty-five grains;* distilled water *four and a half fluidounces;* sugar *three ounces.* Make a solution in the manner directed for preparing solution of iodide of iron. (*Med. Exam.*, vii. 162.) This solution is deemed tonic and alterative. It has been used with advantage by Dr. E. Gillespie, of Brady's Bend, Pa., in tetter, scrofulous tumours, inflammation of the glands both acute and chronic, erysipelas, and amenorrhœa. In tumours and erysipelas, Dr. Gillespie, besides giving the solution internally, applies it to the parts affected, by means of a feather, two or three times a day. Dr. David Alter, of Freeport, Pa., has employed it with seeming benefit in phthisis and other tuberculous diseases. It has also been found useful in bronchocele. The dose of Mr. Parrish's solution is twenty drops, three times a day, gradually increased until its effects are manifested. Bromide of iron is formed as the first step of the process for preparing the officinal bromide of potassium. (See *page* 1348.) B.

BROMIDES OF MERCURY. The *protobromide* is formed by adding bromide of potassium to nitrate of protoxide of mercury. It falls as a white curdy precipitate. The *bibromide* may be obtained by digesting the protobromide in water containing bromine. Mr. A. E. Ebert prepares it by reaction between bromide of potassium and officinal solution of nitrate of mercury. For the particulars of the process see a paper by Mr. Ebert in the *Amer. Journ. of Pharm.*, March, 1867, p. 107. It is in the form of colourless crystals, soluble in water and alcohol. Exposed to heat it melts and sublimes. These bromides are analogous in composition and medical properties to the corresponding iodides of mercury. (See *pages* 1212 and 1213.) The protobromide is given in the dose of a grain daily, gradually increased. The bibromide, like corrosive sublimate, is an irritant poison, and may be administered in doses of the sixteenth of a grain, gradually increased to the fourth, either in the form of pill, or in ethereal solution made by dissolving a grain in a fluidrachm of ether. B.

BRYONY. *White Bryony.* This is the root of *Bryonia alba*, or white bryony, a perennial, climbing, herbaceous plant, growing in thickets and hedges in different parts of Europe. It bears rough, heart-shaped, five-lobed leaves, small yellow monœcious flowers, arranged in racemes, and roundish black berries about the size of a pea. Another species called *B. dioica*, with diœcious flowers and red berries, bears so close a resemblance in character and properties to the preceding, that it is considered by some botanists merely a variety. The roots of both plants are gathered for use. When fresh they are spindle-shaped, sometimes branched, a foot or two in length, as thick as the arm, or even thicker, externally yellowish-gray and circularly wrinkled, within white, succulent, and fleshy, of a nauseous odour, which is lost in great measure by drying, and of a bitter, acrid, very disagreeable taste. The peasants are said sometimes to hollow out the top of the root, and to employ the juice which collects in the cavity as a drastic purge. (*Mérat et De Lens.*) The berries are also purgative, and are used in dyeing.

As kept in the shops, the root is in circular transverse slices, externally yellowish-gray and longitudinally wrinkled, internally of a whitish colour, becoming darker by age, concentrically striated, light, brittle, and readily pulverizable, yielding a whitish powder. Besides a peculiar bitter principle called *bryonin*, the root contains starch in considerable proportion, gum, resin, sugar, a concrete oil, albumen, and various salts. It yields its active properties to water. *Bryonin* may be obtained by mixing the powdered root with one-sixth of its weight of purified animal charcoal, in fine powder, putting the mixture into a percolator, already containing a quantity of animal charcoal equal to that mixed with the bryony, and then percolating successively with strong alcohol, diluted alcohol, and sufficient water to displace the alcoholic liquid. The tincture thus obtained yields the bryonin by spontaneous evaporation. This is extremely bitter, soluble in water and alcohol, insoluble in ether, unaltered by the alkalies, and dissolved by sulphuric acid, with the production of a blue colour. It purges actively in the dose of two grains. (*Am. Journ. of Pharm.*, xxviii.; from *Repert. de Pharm.*, Nov. 1855.) When treated with acids bryonin is resolved into sugar and two peculiar substances, one soluble in ether, called *bryoretin*, the other insoluble in that liquid, and named *hydro-bryoretin*. It is therefore a glucoside (G. F. Walz. See *Am. Journ. of Pharm.*, May, 1859, p. 251.)

Bryony is an active hydragogue cathartic, in large doses sometimes emetic, and disposed, if too largely administered, to occasion inflammation of the alimentary mucous membrane. A fatal case is recorded by Mr. Wm. Herapath, in which narcotic symptoms with vomiting and purging were produced in a woman by an overdose of bryony with jalap, ending in death in thirty-six hours. On dissection, the brain was found congested, the heart empty, and the gastric and intestinal mucous membrane inflamed. (*Pharm.*

Journ., April, 1858, p. 542.) The recent root is highly irritant, and is said, when bruised and applied to the skin, to be capable of producing vesication. The medicine was well known to the ancients, and has been employed by modern physicians; but is now nearly superseded by jalap, which is more certain, and less liable to lose its strength by age. The dose of the powdered root is from a scruple to a drachm. W.

BUXUS SEMPERVIRENS. *Box.* This evergreen shrub is too well known to require description. Though much cultivated in this country as an ornamental plant, it is a native of Europe and Western Asia. The wood is considered diaphoretic in its native countries, and is used in decoction in rheumatism, secondary syphilis, &c. The leaves, which have a peculiar odour and a bitter and disagreeable taste, are said to be purgative in the dose of a drachm. A volatile oil distilled from the wood has been given in epilepsy A tincture formerly enjoyed some reputation as an antiperiodic. (*Mérat et De Lens.*) In 1860 it was determined by Walz that *buxine*, an alkaloid which had been discovered in the leaves of this tree, was identical with the bebeerin of the bebeeru or nectandra bark. (See *page* 573; also *Pharm. Journ.*, Oct. 1869, p. 194.) W.

CABBAGE-TREE BARK. The bark of *Andira inermis* (De Cand.), *Geoffroya inermis* (Willd.), figured in Woodville's Medical Botany, p. 416, t. 151. This is a leguminous tree, with a stem rising to a considerable height, branched towards the top, and covered with a smooth gray bark. The leaves are pinnate, consisting of six or seven pairs of ovate-lanceolate, pointed, veined, smooth, petiolate leaflets, with an odd one at the end. The flowers are rose-coloured, and in terminal panicles, with very short pedicels. The tree is a native of Jamaica and other West India Islands. The bark, which is the part used, is in long pieces, thick, fibrous, externally of a brownish-ash colour, scaly, and covered with lichens, internally yellowish, of a resinous fracture, a disagreeable smell, and a sweetish, mucilaginous, bitterish taste. Its powder resembles that of jalap. Huttenschmidt obtained from it a crystallizable, very bitter substance, having the composition and neutralizing properties of the vegetable alkaloids, and named it *jamaicina*. Two grains of it produced violent purging in pigeons.

Theodore Peckolt says of the wood of the tree, which he calls Andira anthelmintica, that the workmen engaged in sawing it are apt to be affected with inflammation of the eyes, constriction of the throat, excessive thirst, a bitter, burning taste, a troublesome itching over the body, and sometimes eruptions on the skin. By treating a concentrated decoction of the wood with hydrate of lime, filtering after 48 hours, evaporating to the consistence of syrup, and exhausting the residue with alcohol, Peckolt obtained a yellowish-brown colouring matter which he called *andirin*, and which may prove serviceable in painting. He also obtained a peculiar resin by treating the wood with alcohol, filtering, distilling off most of the alcohol, and then precipitating by water. The resin is inodorous, of a bitter, acrid taste, soluble in alcohol, and but partially soluble in ether. This resin, and peculiarly the portion soluble in ether, is the ingredient which gives its irritating properties to the sawdust. (*Chem. Cent. Blatt*, Nov. 17, 1858, p. 813.)

On the continent of Europe, the bark of *Andira retusa* (*Geoffroya Surinamensis*), which grows in Surinam, has also been used. It is considered more powerfully vermifuge, and less liable to produce injurious effects. It has a grayish epidermis, beneath which it is reddish-brown, laminated, compact, and very tenacious, and, when cut transversely, exhibits a shining and variegated surface. In the dried state it is inodorous, but has an austere bitter taste. The powder is of a pale-cinnamon colour.

Cabbage-tree bark is cathartic, and, in large doses, apt to occasion vomiting, fever, and delirium. It is said that these effects are more liable to result if cold water is drunk during its operation, and are relieved by the use of warm water, castor oil, or a vegetable acid. In the West Indies it is esteemed a powerful vermifuge, and is much employed for expelling lumbrici; but it is dangerous if incautiously administered, and instances of death from its use have occurred. It is almost unknown in this country, and does not enter into our officinal catalogues. The usual form of administration is that of decoction, though the medicine is also given in powder, syrup, and extract. The dose of the powder is from a scruple to half a drachm, of the extract three grains, of the decoction two fluidounces. W.

CACTUS GRANDIFLORA. *Night-blooming Cereus.* This well-known flowering plant has recently been introduced into therapeutics. Dr. Rubini has used with success, in functional palpitations of the heart, a tincture made of four ounces of the fresh stems and flowers and a pint of alcohol of 95°, by macerating for a month, and filtering. He gives from one to five drops three times a day. (*N. Y. Med. Record*, Sept. 1, 1868, p. 299.)

CAHINCA. This medicine attracted at one time considerable attention. The name of *cahinca* or *cainca* was adopted from the language of the Brazilian Indians. The Portuguese of Brazil call the medicine *raiz pretta* or black root. When first noticed in Europe, it was supposed to be derived from the *Chiococca racemosa* of Linnæus, which was known to botanists as an inhabitant of the West Indies. But Martius, in his "Specimen Materiæ Medicæ Brasiliensis," describes two other species of Chiococca, *C. anguifuga* and *C. densifolia*, which afford roots having the properties of the root ascribed to *C. racemosa;* and, as the medicine was brought from Brazil, there seemed to be good reason for referring it to one or both of the plants named by that botanist. A. Richard, however, received from Brazil specimens of *C. racemosa* as the cahinca plant.

A specimen brought into this market consisted of cylindrical pieces, varying in size from the thickness of a straw to that of the little finger, somewhat bent or contorted, slightly wrinkled longitudinally with occasional small asperities, internally ligneous, externally covered with a thin, brittle, reddish-brown bark, having a light-brown or brownish ash-coloured epidermis. The cortical portion, which was of a resinous character, had a bitter disagreeable taste, somewhat acrid and astringent; the ligneous part was quite tasteless. The virtues of the root reside almost exclusively in its bark. They are extracted by water and alcohol. Cahinca has been analyzed by several chemists. Four distinct principles were discovered in it by Pelletier and Caventou:—1. a crystallizable bitter substance, believed to be the active principle, and called *cahincic acid;* 2. a green fatty matter of a nauseous odour; 3. a yellow colouring matter; and 4. a coloured viscid substance. Rochleder and Hlasiwetz found also caffeotannic acid. By these chemists a tincture, obtained by boiling the bark in alcohol, was precipitated first with a spirituous solution of acetate of lead, and afterwards, having been previously filtered, with the tribasic acetate of lead. The first precipitate consisted chiefly of caffeotannate and a portion of cahincate of lead, the second of cahincate of lead exclusively. To obtain the caffeotannic acid separate, the first precipitate was treated with sulphuretted hydrogen, and afterwards with neutral acetate of lead, and in like manner several times, until at length a pure caffeotannate of lead remained, which, on decomposition, yielded an acid identical with the tannic acid of coffee. The cahincic acid was obtained by treating the second precipitate with sulphuretted hydrogen, and concentrating the resulting liquid. The chemists last mentioned gave as its formula $C_{16}H_{13}O_7$. (*Chem. Gaz.*, ix. 121.) Cahincic acid is white, without smell, of a taste at first scarcely perceptible, but afterwards extremely bitter and slightly astringent, of difficult solubility in water, but readily soluble in alcohol, permanent in the air, and unaltered at 212°. It reddens vegetable blues, and unites with the alkalies, but does not form crystallizable salts. It is thought to exist in the root as subcahincate of lime.

Medical Properties. Cahinca is tonic, diuretic, purgative, and emetic. In moderate doses it gently excites the circulation, increases the discharge of urine, and produces evacuations from the bowels; but is rather slow in its operation. It may be made to act also as a diaphoretic, by keeping the skin warm, using warm drinks, and counteracting its purgative tendency. In some patients it occasions nausea and griping, and in very large doses always acts powerfully both as an emetic and cathartic. In Brazil it has long been used by the natives as a remedy for the bites of serpents; and its Indian name is said to have been derived from this property. According to Martius, the bark of the fresh root is rubbed with water till the latter becomes charged with all its active matters; and the liquid, while yet turbid, is taken in such quantities as to produce the most violent vomiting and purging, preceded by severe spasmodic pains. Patrick Brown speaks of the root of *C. racemosa* as very useful in obstinate rheumatisms. But the virtues of cahinca in dropsy, though well known in Brazil, were first made known to the European public in the year 1826, by M. Langsdorf, Russian Consul at Rio Janeiro. Achille Richard afterwards published a few observations in relation to it in the *Journal de Chimie Médicale;* and its properties were subsequently investigated by numerous practitioners. M. François, of Paris, contributed more than any other physician to its reputation. It was considered by him superior to all other remedies in dropsy. But general experience has not confirmed the partial estimate of Dr. François; and, having been found at least equally uncertain with other diuretics, the medicine is now little used. It was employed in substance, decoction, extract, and tincture. The powdered bark of the root was given as a diuretic and purgative, in a dose varying from a scruple to a drachm; but the aqueous or spirituous extract was preferred. The dose of either of these is from ten to twenty grains. Dr. François recommended that, in the treatment of dropsy, a sufficient quantity should be given at once to produce a decided impression, which should afterwards be maintained by smaller doses, repeated three or four times a day. W.

CALAMINA. *Calamine. Lapis Calaminaris.* Calamine is introduced into this part of the Dispensatory, because dismissed from the Pharmacopœias. The term *calamine* is applied by mineralogists indiscriminately to two minerals, scarcely distinguishable by their external characters, the *carbonate* and *silicate* of zinc. The term, however, in the pharmaceutical sense refers to the native *carbonate* only. The silicate is sometimes called *electric calamine.* Calamine is found in the United States, but more abundantly in Germany and England. It usually occurs in compact or earthy masses, or concretions, of a dull appearance, readily scratched by the knife, and breaking with an earthy fracture; but sometimes it is found crystallized. Its colour is very variable; being, in different specimens, grayish, grayish-yellow, reddish-yellow, and, when very impure, brown or brownish-yellow. Its sp. gr. varies from 3·4 to 4·4. Before the blowpipe it does not melt, but becomes yellow and sublimes. When of good quality, it is almost entirely soluble in the dilute mineral acids; and, unless it has been previously calcined, emits a few bubbles of carbonic acid. If soluble in sulphuric acid, it can contain but little carbonate of lime, and no sulphate of baryta. Ammonia, added to the sulphuric solution, throws down the oxide of zinc, mixed with the subsulphate, and takes it up again when added in excess. If copper be present the ammonia will give rise to a blue colour; if iron, the alkali will throw down the sesquioxide, not solu-

ble in an excess of the precipitant. The officinal calamine is distinguished from the electric calamine, which is a silicate of zinc, by dissolving in warm nitric acid without gelatinizing, and by not being rendered electric by heat.

Impurities. According to Mr. Robert Brett, calamine, as sold in the English shops, is frequently a spurious mixture containing only traces of zinc. He analyzed six specimens, and found them to contain from 78 to 87·5 per cent. of sulphate of baryta, the rest consisting of sesquioxide of iron, carbonate of lime, sulphate (sulphuret) of lead, and mere traces of zinc. When acted on by muriatic acid, the spurious calamine, in powder, evolved sulphuretted hydrogen, and was only in small part dissolved, the great bulk of it remaining behind as sulphate of baryta. (*Amer. Journ. of Pharm.*, ix. 173.) The results of Mr. Brett have been confirmed by Dr. R. D. Thomson, Mr. D. Murdock, and Mr. E. Moore. Dr. Thomson thinks the spurious calamine is made of sulphate of baryta and chalk, coloured with Armenian bole. The late Mr. Jacob Bell, of London, held the more probable opinion that it is the native sulphate of baryta, deriving its colour from iron, which is a mineral having some resemblance to calamine. Mr. Midgley, indeed, states that the miners in England distinguish two calamines, *brass calamine*, which is sold to the makers of brass, and *baryta calamine*, which is really the native amorphous sulphate of baryta, and which is furnished to the druggists in the place of the genuine native carbonate of zinc. Even the genuine calamine of the shops is impure, usually containing iron and copper, and various earthy matters. That which has been calcined, to render it more readily pulverized, contains little or no carbonic acid. In view of these facts, the revisers of the U. S. Pharmacopœia of 1850 deemed it proper to introduce, as a new officinal, the *pure* carbonate of zinc, obtained by precipitation. (See *Zinci Carbonas Præcipitata.*) The crystallized variety is anhydrous, and consists of one eq. of carbonic acid 22, and one of protoxide of zinc 40·3 = 62·3. The compact and earthy varieties are said to contain one eq. of water.

Prepared Calamine. Calamina Præparata. Calamine must be impalpable before being used in medicine. In this state it forms *prepared calamine*, which, though but recently an officinal preparation, has shared the fate of its original, and been discarded from the Pharmacopœias. The following is the U. S. formula of 1850. "Take of Calamine *a convenient quantity.* Heat it to redness, and afterwards pulverize it; then reduce it to a very fine powder in the manner directed for Prepared Chalk." (*U. S.*) The object of this process is to bring the native carbonate of zinc, or calamine, to the state of an impalpable powder. It is first calcined, to render it more readily pulverizable, and then levigated and elutriated. During the calcination, water and more or less carbonic acid are driven off; so that little else remains than the oxide of zinc, and the earthy impurities originally existing in the mineral. Calamine, as sold in England, is almost always spurious, consisting wholly or principally of native sulphate of baryta, coloured with sesquioxide of iron. The same remark applies to the calamine in the shops of the United States. Of six samples analyzed by Mr. F. Bringhurst, of Wilmington, Del., five were totally devoid of zinc, and the sixth contained only 2 per cent. of the oxide. (*Am. Journ. of Pharm.*, July, 1857.) Prepared calamine is in the form of a pinkish or flesh-coloured powder, of an earthy appearance. Sometimes it is made up into small masses. It is used only as an external application, being employed as a mild astringent and exsiccant in excoriations and superficial ulcerations. For this purpose it is usually dusted on the part, and hence the necessity for its being in very fine powder. It is often employed in the form of cerate. (See *Ceratum Calaminæ*, page 1083.) The evidence being conclusive that the powder almost universally sold as prepared calamine is a spurious article, consisting chiefly of sulphate of baryta, whatever therapeutic effects it may have exerted, must be attributed to that salt. B.

From a recent communication by Mr. R. H. Davis to the *Pharm. Journ. and Trans.* (Oct. 1866, p. 207) it appears, as the result of an examination of numerous specimens of calamine, obtained from different shops in Great Britain, that a great improvement has taken place in the character of this drug, and that greater reliance may now be placed on it as found in the market, than was the case a few years past. W.

CALENDULA OFFICINALIS. *Marigold.* This well-known garden plant was formerly much employed in medicine. It has a peculiar, rather disagreeable odour, which is lost by drying, and a bitter, rough, saline taste. Among its constituents is a peculiar principle, called *calendulin*, discovered by Geiger most abundantly in the flowers, and considered by Berzelius as analogous to bassorin, though soluble in alcohol. The plant was thought antispasmodic, sudorific, deobstruent, and emmenagogue, and was given in low forms of fever, scrofula, jaundice, amenorrhœa, &c. Both the leaves and flowers were used; but the latter were preferred, and were usually administered in the recent state, in the form of tea. An extract was also prepared, and employed in cancerous and other ulcers, sick stomach, &c. At present marigold is very seldom used in regular practice; but, in a communication from Dr. Ab. Livezey, of Philadelphia, to the *Med. and Surg. Reporter* (Aug. 1, 1868, p. 85), the author states that he habitually uses a strong tincture of the flowers probably saturated, as an application to incised and lacerated wounds and contusions, and has invariably found it to exercise a peculiar curative influence, preventing inflammation and suppuration, and promoting the healing of the wounds when the parts were brought into contact. W.

CALLITRICHE VERNA. (*Gray's Manual*, p. 384.) *Water Starwort.* This is a small, herbaceous, indigenous water-plant, growing in shallow streams, ditches, or ponds, with a long stem under water, and leaves floating on the surface. This and several other species of the same genus are supposed to have diuretic properties, and are given in decoction in dropsical affections and complaints of the urinary organs. W.

CALOTROPIS GIGANTEA. Brown. *Asclepias gigantea.* Linn. Under the name of *madar* or *mudar*, a medicine has been employed in the East Indies, with great asserted advantage. It is the bark of the root of a species of Calotropis, generally considered as *C. gigantea*, but asserted by Dr. Casanova to be a distinct species, and named by him *C. Madarii Indico-orientalis. C. gigantea* is a native of Hindostan, and has been introduced into the West Indies, where it is now naturalized. The bark, as employed, is without epidermis, of a whitish colour, nearly or quite inodorous, and of a bitter somewhat nauseous taste. It appears to have the general properties of many other acrid medicines; in small doses, increasing the secretions, and in larger, producing nausea and vomiting. According to Dr. Casanova, who published an essay upon the subject at Calcutta, it is especially directed to the skin, the capillaries and absorbents of which it stimulates to increased action. It is chiefly recommended as a remedy in the obstinate cutaneous diseases of tropical climates, such as elephantiasis and leprosy. It has been employed also in syphilis, dropsy, rheumatism, and hectic fever; and Mr. J. J. Durant states that he has found it an excellent substitute for ipecacuanha in acute dysentery, giving it in the same dose. (*Am. Journ. of Med. Sci.*, Oct. 1866, p. 526; from *India Med. Gaz.*, May, 1866.) It is given in substance in the dose of from three to twelve grains, three times a day, and gradually increased till it affects the system. The plant has of late years been applied to various economical purposes in India, independently of its medical use. The most important of these is the manufacture of cords, ropes, &c. from the fibres of its branches, which are said to possess many of the properties of flax, and to be applicable to the making of cloth. (*Chem. News*, No. 167, p. 76.) W.

CAM WOOD. A red dye-wood, procured from the *Baphia nitida* of De Candolle, a leguminous tree, growing on the Western Coast of Africa. The wood is usually kept in the shops in the ground state. It yields its colouring matter scarcely at all to cold water, slightly to boiling water, and readily to alcohol and alkaline solutions. This colouring matter is thought to be identical with santalin. W.

CANARY SEED. The seeds of *Phalaris Canariensis*, an annual plant belonging to the grasses, originally from the Canary Islands, but now growing wild in Europe and the United States, and cultivated in many places. The seeds are ovate, somewhat compressed, about two lines long, shining, and of a light yellowish-gray colour externally, and brownish within. Their chief constituent is starch. They were formerly esteemed medicinal, but are now used only for emollient cataplasms. They are nutritive, and their meal is said to be mixed, in some places, with wheat flour, and made into bread. They are used as food for Canary birds. W.

CAOUTCHOUC. *Gum Elastic. Indian Rubber.* Many lactescent plants belonging to the natural orders *Artocarpeæ*, *Apocynaceæ*, and *Euphorbiaceæ*, and growing in hot countries, yield products analogous to caoutchouc; but, as found in general commerce, this substance is the concrete juice of different species of Siphonia, especially the *Siphonia Cahuchu* of Schreber and Willdenow, identical with *Siphonia elastica* of Persoon, the *Jatropha elastica* of the younger Linnæus, and the *Hevea Guianensis* of Aublet. This is a large tree, growing in Brazil, Guiana, and probably also in Central America (*Journ. of Phil. Col. of Pharm.*, iii. 292); but the product is brought chiefly from the port of Para, in Brazil. On being wounded, the tree emits a milky juice, which concretes on exposure, and constitutes the substance in question. Caoutchouc comes to us in large flat pieces, or moulded into various shapes. The latter are formed by applying successive layers of the juice upon moulds of clay, which are broken and removed when the coating has attained a sufficient thickness and consistence. In the drying of these layers they are exposed to smoke, which gives to the concrete mass a blackish colour. The juice, when it concretes by exposure to the air, assumes on the outer surface a yellowish-brown colour, while the mass remains white or yellowish-white within. It is said that a little alum facilitates the coagulation, while ammonia retards it; so that a little of the latter may be advantageously added, when it is desired to keep the milky juice in the liquid state. (R. Spruce, *Pharm. Journ.*, xv. 118.) The recent juice contains, according to Faraday, 1·9 per cent. of vegetable albumen, traces of wax, 7·13 per cent. of a bitter azotized substance soluble in water and alcohol, 2·9 of a substance soluble in water but insoluble in alcohol, 56·37 of water with a little free acid, and only 31·7 of the pure elastic principle to which chemists have given the name of caoutchouc. Besides these principles the concrete juice, as it reaches us, generally contains soot derived from the smoke used in drying it. *Pure caoutchouc* is nearly colourless, and in thin layers transparent. It is highly elastic, lighter than water, without taste and smell, fusible at about 248°, remaining unctuous and adhesive upon cooling, inflammable at a higher temperature, insoluble in water, alcohol, the weak acids, and alkaline solutions, soluble in ether when entirely freed from alcohol, soluble also in chloroform and most of the fixed and volatile oils, though, in the latter, at the expense of its elasticity. It is said, however,

that the oils of lavender and sassafras dissolve it without change, and that, when precipitated by alcohol from its solution in cajeput oil, it is still elastic. But its best solvents, for practical purposes, are coal-naphtha or benzine, the empyreumatic oil obtained by distilling caoutchouc itself, and pure oil of turpentine. According to Dr. Bolley, the best method of effecting its solution, for the preparation of a varnish, is first to digest it, cut in small pieces, in bisulphuret of carbon, which converts it into a jelly, and then to treat this jelly with benzine. A larger proportion is thus taken up than by any other method. (See *Am. Journ. of Pharm.*, Sept. 1862, p. 414.) Caoutchouc is not affected by atmospheric air, chlorine, muriatic or sulphurous acid gas, or ammonia. It consists, according to Faraday, of 87·2 parts of carbon, and 12·8 of hydrogen. The unpleasant odour acquired by caoutchouc, through its property of absorbing gases, which almost unfits it sometimes for purposes to which it is otherwise applicable, may be obviated by exposing it to the still greater power of absorption possessed by charcoal. For the method of applying charcoal for the purpose, the reader is referred to the *Amer. Journ. of Pharm.* (May, 1867, p. 236).

By the action of sulphur caoutchouc acquires properties which greatly increase its value in the arts. It becomes of a black colour and horny consistence, preserves its elasticity under the influence both of heat and cold, is compressible with great difficulty, and resists the ordinary solvents, such as petroleum and oil of turpentine. In this state it is said to be *vulcanized*. The discovery of the process of *vulcanization* is ascribed to Mr. Charles Goodyear, of New York. (*Chem. Gaz.*, x. 193.) It consists in submitting caoutchouc in thin sheets to the action of a mixture, composed of 40 parts of bisulphuret of carbon and 1 of chloride of sulphur. For fuller details the reader is referred to the *Journ. de Pharm.* (3e sér., xvii. 205). But the same object may be effected in other methods. When thin layers of caoutchouc are immersed for two or three hours in melted sulphur at the heat of 240° F., they are penetrated by the sulphur, but undergo no change of properties. If now heated in an inert medium to a temperature of from 275° to 320°, a chemical reaction takes place, and the vulcanized product is obtained. The same result takes place if the caoutchouc be first pounded with from 12 to 20 per cent. of finely powdered sulphur, and then heated to the temperature requisite for vulcanization. In either case, a portion of uncombined sulphur remains mechanically mixed with the vulcanized caoutchouc, from which it may be separated by various solvents, such as solutions of caustic soda or potassa, bisulphuret of carbon, oil of turpentine, anhydrous ether, &c. The *desulphurated* product thus obtained, while exempt from the disadvantages arising from the reaction of free sulphur, is more porous than before. (*Ibid.*, xxi. 366.) Another mode of vulcanization, proposed by Mr. Humphrey, is based on the property of dissolving chloride of sulphur possessed by petroleum, which is substituted for sulphuret of carbon. It is necessary that the petroleum should be perfectly freed from water, by which the chloride of sulphur is immediately decomposed. This is effected by agitating the petroleum of commerce long and energetically with one-tenth of concentrated sulphuric acid; after which, the acid being allowed to subside, the petroleum is decanted, and treated with 200 to 250 grammes (about half a pound) of powdered quicklime for each hectolitre (26·4 gallons), with a little peroxide of manganese. The liquid, being now distilled, is fit for the vulcanization of the caoutchouc. According to the *Chemist*, there is no economy in the substitution of petroleum for the sulphuret of carbon; but the new process has a great advantage in regard to the health of the workmen, and the facility of the work. (*Ibid.*, 4e sér., ii. 386.)

Caoutchouc is used for erasing pencil marks; in the formation of flexible tubes for the laboratory, and of catheters, bougies, pessaries, dilators, and other instruments for surgical purposes; in the melted state, as a luting to the joints of chemical apparatus; in the shape of thin layers, for covering the mouths of bottles, and for other purposes in which the exclusion of air and moisture is requisite; in the manufacture of water-proof cloth; as a varnish, and for numerous other purposes, to which its elasticity, and the resistance which it offers to the ordinary solvents, and to other powerful chemical agents, peculiarly adapt it. It is now, however, asserted that caoutchouc, whether vulcanized or not, is unfit for effecting the junction of apparatus, when it is necessary to obtain gases quite pure; as it admits the escape of a portion of the gas and the entrance of the air, according to the law of diffusion established by Prof. Graham. The inconvenience, however, may be remedied by covering the caoutchouc with a coating of asphaltum dissolved in tar. (*Journ. de Pharm.*, 4e sér., iv. 157.) Bands of caoutchouc have, by their elasticity, been found useful in the reduction of dislocations. (*Br. and F. Med.-chir Rev.*, Jan. 1867, p. 264.) Still another surgical use of the vulcanized caoutchouc is for plates to fill clefts and vacancies in the palate, etc. (*Ed. Med. Journ*, Aug 1867, p. 176.) It may be brought to the state of thin layers, by softening the small flasks of it in ether containing alcohol, or boiling them in water for fifteen minutes, and then distending them by means of air forced into them; and the same end may be attained by spreading its naphtha or ethereal solution upon a smooth surface, and allowing the solvent to evaporate. Tubes of caoutchouc may be made from its solution, or from the juice imported in the liquid state. A *court-plaster* prepared with caoutchouc has been considerably used, and from its impermeability by moisture is sometimes valuable. (See *Am. Journ. of Pharm.*, xv. 88.) A convenient sticking-plaster may be prepared by spreading the liquid caoutchouc,

by a stiff brush, upon calico, soft leather, or thin sheets of vulcanized Indian rubber as found in the shops. Small thin pieces of caoutchouc may be very advantageously employed to suppress hemorrhage from leech-bites, &c., by first softening one surface of the piece by a taper, and when cool applying it firmly over the bleeding point. The cavity of a decayed tooth may be lined with caoutchouc, so as to prevent the access of air, and thus relieve pain, by fastening a piece firmly around the end of a rod, liquefying the surface by heat, then introducing it with pressure into the cavity, and again withdrawing it. The milky juice obtained from the plant, and prevented from coagulating in the bottle by a little solution of ammonia, has been recommended as a local application in cutaneous eruptions, burns, erysipelas, &c., in which it proves useful by concreting, and forming an elastic covering, impermeable to moisture and the air. A solution of caoutchouc in chloroform is used for the same purpose; the menstruum evaporating quickly and leaving a thin layer of the elastic substance on the surface. An excellent glue may be made by dissolving, with the aid of heat and agitation, 3 parts of caoutchouc in 30 of naphtha, and adding 64 parts of finely-powdered shellac. It may be obtained in sheets by pouring it when hot on plates of metal. (*Am. Journ. of Pharm.*, March, 1867, p. 185.) Caoutchouc has been given internally in phthisis, in the dose of one or two grains, gradually increased. W.

CAPPARIS SPINOSA. *Caper-bush.* A low, trailing shrub, growing in the South of Europe and North of Africa. The buds or unexpanded flowers, treated with salt and vinegar, form a highly esteemed pickle, which has an acid, burning taste, and is considered useful in scurvy. The dried bark of the root was formerly officinal. It is in pieces partially or wholly quilled, about one-third of an inch in mean diameter, transversely wrinkled, grayish externally, whitish within, inodorous, and of a bitterish, somewhat acrid, and aromatic taste. It is considered diuretic, and was formerly employed in obstructions of the liver and spleen, amenorrhœa, and chronic rheumatism. W.

CARAMANIA GUM. Under this name a large quantity of a peculiar product was a few years since brought into this market for sale, a specimen of which, kindly sent us by Mr. B. R. Smith, we have had the opportunity of examining. No history of its origin came with it, but, judging from its name and character, we have little doubt that it is identical with the Caramania gum, noticed under the head of tragacanth, as one of the substances used in the adulteration of that drug. It is in pieces differing in size from that of a small pea to that of a Spanish chestnut, of various shapes, sometimes irregularly spherical, sometimes elongated, often bent or somewhat contorted, occasionally appearing as if several smaller pieces had adhered longitudinally, smoothish on the surface, generally pale, but in some pieces brown, and in most of a faint reddish hue, and translucent in all. The gum is very hard yet brittle, without smell, nearly tasteless, and very gradually softening when held in the mouth. At our request, Professor Procter subjected a portion to examination, and found it, when macerated in cold water, gradually to swell up like tragacanth, and like it, to give up a part of its substance to water, but less than tragacanth. After four or five days it ceased to swell, and the bulky hydrated masses formed appeared like clouded calf's feet jelly, and with little cohesiveness, in this respect resembling Bassora gum. The dissolved portion was mucilaginous but not thick. It was precipitated by subacetate of lead, but less decidedly than arabin. Oxalate of ammonia caused a white precipitate, indicating the presence of lime. It was not coagulated by borax or sesquichloride of iron, nor was it precipitated by alcohol in flakes like arabin. The undissolved portion, boiled with diluted sulphuric acid, was broken down, assuming a syrupy consistence, and yielded to Trommer's test evidence of the presence of glucose, which must have been formed under the influence of the acid, as the first watery solution contained none. Prof. Procter failed to find any signs of lead on the surface, so that the statement made by Mr. Maltass in relation to the Caramania gum used to adulterate tragacanth is not applicable to this. But there was no reason to expect it, as this was offered in the market under its own and not a false name. It is very obviously the concrete exuded juice of a tree, but the particular plant which yields it is unknown. So far as examined, it corresponds to a considerable extent with Bassora gum; and, as it probably comes from Caramania, a province in the eastern part of Asia Minor, it is not impossible that the two are of the same origin, the Bassora gum being carried down to the Persian Gulf.* W.

CARANNA. *Gum Caranna.* A resinous substance, in pieces of a blackish-gray colour, externally dark-brown, internally somewhat shining and translucent, brittle and pulverizable when dry, but, in the recent state, soft and adhesive like pitch, easily fusible, of an agreeable balsamic odour when heated, and of a bitterish resinous taste. (*Geiger.*) It is said to be derived from the *Amyris Caranna* of Humboldt, a tree growing in Mexico and South America. Geiger refers it also to *Bursera gummifera* of the West India Islands; but the resin obtained from this tree is described by the French writers under the name of *resine de Gomart*, or *resine de chibou*, or *cachibou*, and is said to bear a close resemblance to the resin *tacamahac*. W.

* After the article upon Caramania gum had been sent to the press, a specimen was shown us, labeled *false tragacanth*, which had been kept for many years in a materia medica cabinet, and had probably been separated from a parcel of adulterated tragacanth, and which so closely resembled the gum described in the text, that we have no doubt of their identity in character and origin. According to Mr. Maltass, Caramania gum is used in the adulteration of tragacanth to the extent, in different varieties, of from 25 to 100 per cent. (*Pharm. Journ.*, xv. 20.)

CARBAZOTIC ACID. *Picric Acid. Nitropicric Acid.* This acid is obtained by the action of nitric acid on indigo, silk, and other substances. It may be cheaply prepared from coal-tar creasote (impure phenylic or carbolic acid), or from Australian gum It is in pale-yellow shining scales, soluble in water, to which it gives a strong yellow colour and very bitter taste. Its salts crystallize readily, and explode when heated. The potassa salt is so sparingly soluble, that an alcoholic solution of the acid may be used as a test for this alkali. Its formula is $C_{12}(H_2 3NO_4)O+HO$; being phenylic acid, with three eqs. of hydrogen replaced by three of hyponitric acid. It is largely used in dyeing; producing magnificent yellow colours, and, in connection with indigo or Prussian blue, different shades of green.

The salts which picric or carbazotic acid forms with potassa and soda, are yellow and bitter; and it is in this state that the acid is often used in dyeing. It should be understood, however, that these salts are capable of exploding violently at elevated temperatures or from a severe blow; and very fatal consequences occurred from such an explosion of a large quantity of picrate of potassa, in one of the magazines of Paris, in March, 1869. (*Journ. de Pharm.*, Avril, 1869, p, 247.)

From the therapeutic trials, made with carbazotic acid, it is inferred to be tonic and astringent. In large doses it is poisonous; 10 grains of it having been sufficient to kill a dog in less than two hours. (*Taylor on Poisons*, p. 793.) It was first used in intermittent fever by Dr. Bell, of Manchester, who thought it might be employed as a cheap substitute for quinia. Its salts are preferred to the free acid, which is apt to cause cramps of the stomach; and those most approved are the *carbazotates of ammonia and iron.* Dr. T. Moffat cured several cases of cephalalgia by the iron salt, and cases of intermittent fever and anæmia by the ammonia salt. Mr. Alfred Aspland has given an ample trial to the acid and the salt of ammonia, and confirms the statements previously made of their efficacy, having found them especially useful in intermittent fever, and applicable to all cases in which quinia is indicated. (*Med. Times and Gaz.*, Sept. 1862, p. 289.) The dose of either, administered in pills, is from a quarter to half a grain, three times a day. Mr. Aspland began with a grain three times a day, and increased to 4 grains for a dose. A curious effect of these salts, first observed by Dr. Moffat, is to produce, in many cases, a temporary yellowness of the skin and conjunctiva, as in jaundice. The effect is generally induced when about 15 grains of the acid have been taken. The urine also becomes orange-coloured. The colour disappears in two or three weeks after ceasing to use the medicine.

Carbazotate of iron may be prepared by digesting pure crystallized carbazotic acid with an excess of recently precipitated sesquioxide of iron and water at a gentle heat, till the acid has disappeared, filtering, and evaporating the filtrate at a temperature not exceeding 212°. Thus prepared it is amorphous, reddish-brown in mass, lighter-coloured in powder, of an astringent and intensely bitter and persistent taste, and readily soluble in water. On account of its bitterness, it is best given in pill. (See *Am. Journ. of Pharm.*, March, 1863, p. 169.) B.

CARBONIC OXIDE. Dr. Ozanam has proposed this gas as an anæsthetic; his opinion of its fitness being founded on twenty-five experiments on rabbits, and five on man; but his results show it to be dangerous, on account of the sudden manner in which it sometimes acts, and its supposed advantages are problematical. (See *B. and F. Medico-chir. Rev.*, Am. ed., July, 1857, p. 176.) B.

CARBURET OF IRON. *Ferri Carburetum. Plumbago. Black Lead.* This substance has been used both internally and externally in cutaneous affections. For medicinal use it is reduced to very fine powder, and purified by being boiled in water, and digested with dilute nitromuriatic acid. The dose is from five to fifteen grains or more, three or four times a day, given in the form of powder or pill. The ointment is made by mixing from two to six drachms with an ounce of lard. B.

CARDAMINE PRATENSIS. *Cuckoo-flower.* This is a perennial herbaceous plant, with a simple, smooth, erect stem, about a foot in height. The leaves are pinnate; the radical, composed of roundish irregularly toothed leaflets, those of the stem alternate, with leaflets which become narrower, more entire, and pointed as they ascend. The flowers are purplish-white or rose-coloured, and terminate the stem in a raceme approaching the character of a corymb. The plant is a native of Europe, and is found in the northern parts of our continent, about Hudson's Bay. It is a very handsome plant, abounding in moist meadows, which it adorns with its flowers in the months of April and May. The leaves are bitterish, and slightly pungent, resembling in some measure those of watercresses, and like them supposed to be possessed of antiscorbutic properties. In Europe they are sometimes added to salads. The flowers have the same taste as the leaves, and, when fresh, a somewhat pungent odour. When dried they become inodorous and nearly insipid. They formerly possessed the reputation of being diuretic, and, since the publication of a paper by Sir George Baker, more than half a century ago, have been occasionally used as an antispasmodic in various nervous diseases, such as chorea and spasmodic asthma, in which they were successfully employed by that physician. They produce, however, little obvious effect upon the system, and are not employed in this country. W.

CARYA. *Hickory. Juglans.* Linn. Several species of the genus Carya, of Nuttall,

separated by that botanist from the *Juglans* of Linnæus, grow within the limits of the United States, of which *C. olivæformis* bears the *pecan-nut* of the South-West, *C. alba*, the fruit so well known by the name of *shell-bark*, derived probably from the ragged state of the bark of the stem, *C. sulcata*, another variety of shell-bark, and *C. tomentosa*, the common thick-shelled hickory-nut. Other indigenous species are *C. amara*, *C. glabra*, and *C. microcarpa*. The leaves of most if not all of these trees are somewhat aromatic and astringent, and the bark astringent and bitter; and both no doubt possess medical virtues. Attention was called to them by Mr. Frederick Stearns, of Detroit, in a paper on the medical plants of Michigan, read before the American Pharmaceutical Association, and published in their *Proceedings* (1859, p. 249). Mr. Stearns bases his opinion of the probable virtues of these products upon a communication made to him by Mr. Caffinbury, of the same State, who had found great advantage from chewing the inner bark of the hickory in dyspepsia, and has used a tincture made from the same bark with great success in the treatment of intermittent fever. The use of the remedy had extended in his neighbourhood, and many employ it habitually in the same complaint, some of whom very wisely prefer the infusion to the tincture, as it has been found equally effectual. W.

CASTANEA. *Chinquapin.* This held a place in the secondary catalogue of our Pharmacopœia, until the late revision, when it was discarded. It is the bark of *Castanea pumila*, or chinquapin, of our Atlantic States. We present here the short account of it formerly contained in the first part of this work. The genus Castanea belongs to Monœcia Polyandria of the Linnæan system, and to the natural order Cupuliferæ, with the following generic character:—"MALE. *Ament* naked. *Calyx* none *Corolla* five-petaled. *Stamens* ten to twenty. FEMALE. *Calyx* five or six leaved, muricate. *Corolla* none. *Germs* three. *Stigmas* pencil formed. *Nuts* three, included in the echinated calyx." (*Willd.*)—The chinquapin is a shrub or small tree, which, in the Middle States, rarely much exceeds seven or eight feet in height, but, in the Carolinas, Georgia, and Louisiana, sometimes attains an elevation of thirty or forty feet, with a diameter of trunk equal to twelve or fifteen inches. The leaves are oblong, acute, mucronately serrate, and distinguished from those of the chestnut, which belongs to the same genus, by their whitish and downy under surface. The barren flowers are grouped upon axillary peduncles, three or four inches long; the fertile aments are similarly disposed, but less conspicuous. The fruit is spherical, covered with short prickles, and encloses a brown nut, which is sweet and edible, but differs from the chestnut in being much smaller, and convex on both sides. The tree extends from the banks of the Delaware southward to the Gulf of Mexico, and south-westward to the Mississippi. It is most abundant in the southern portions of this tract of country. The bark is the part used. It is astringent and tonic, and has been employed in the cure of intermittents.

The leaves of our common indigenous chestnut-tree, *Castanea vesca*, have been used with great asserted advantage in hooping-cough, by Dr. J. Unzicker, of Cincinnati, who found them to give decided relief to the patient in the course of two weeks, after which the complaint rapidly declined to its termination. He makes a hot infusion in the proportion of three or four drachms to a pint, and gives the infusion, sweetening freely, through the day, as much as the child will drink. (*Med. and S. Reporter*, Oct. 26, 1867, p. 355.) Dr. J. Ludlow, also of Cincinnati, has followed the practice of Dr. Unzicker, with at least equal success. (*Am. Jour. of Med. Sci.*, April, 1869, p. 568; from *Cincin. Lancet and Observer*, March, 1869.) The first notice, however, that we have seen of the use of chestnut leaves in hooping-cough, was contained in a paper in the *Proceedings of the American Pharmaceutical Association* (A. D. 1862), by Mr. Geo. C. Close, of Brooklyn, N. Y., who received his information originally from an eminent physician of New York, who had been in practice in that city more than thirty years, by whom he was told that chestnut leaves were the best remedy he had ever met with in that disease. (See *Am. Journ. of Pharm.*, Jan. 1862, p. 66.) W.

CATALPA CORDIFOLIA. *Bignonia Catalpa.* Linn. *Catalpa-tree*, or *Catawba-tree.* This is a beautiful indigenous flowering tree, occasionally cultivated for ornamental purposes. It is reputed to be poisonous. The seeds have been employed by several practitioners of continental Europe in asthma. M. Automarchi recommends a decoction, made by boiling twelve ounces of water with three or four ounces of the seeds down to six ounces, the whole to be given morning and night; but, if there be any foundation for the prevalent opinion as to the poisonous character of the tree, this might be a hazardous dose; and it would be advisable, in any one who might be disposed to imitate the practice, to begin with much smaller doses, and to increase until the effects of the medicine on the system are ascertained. W.

CAULOPHYLLUM THALICTROIDES. (*Michaux.*) *Leontice thalictroides.* Linn. *Blue Cohosh. Pappoose Root.* (*Gray's Manual*, p. 20.) An indigenous, perennial, herbaceous plant, with matted, knotty rhizomas, from which rises a single, smooth stem, about two feet high, naked till near the summit, where it sends out a large triternately compound leaf, and ending in a small raceme or panicle of greenish-yellow flowers, at the base of which is often a smaller biternate leaf. The whole plant when young, as well as the seeds,

which are about as large as peas, is glaucous. It is the only known species of the genus. It is found in most parts of the United States, growing in moist rich woods. The root is the part used. This has a sweetish, pungent taste, and yields its virtues to water and alcohol. It is deemed especially emmenagogue, and is thought also to promote the contractions of the uterus, for which purpose, we learn, it is much employed by the "eclectic" practitioners, who consider it also possessed of diaphoretic and various other remedial properties. It is given in decoction, infusion, or tincture; the first two being made in the proportion of an ounce to a pint of water, the last of four ounces to a pint of spirit. The dose of the decoction or infusion is one or two fluidounces, of the tincture one or two fluidrachms. W.

CEANOTHUS AMERICANUS. *New Jersey Tea. Red-root.* A small indigenous shrub, growing throughout the United States. The root is astringent, and imparts a red colour to water. It is said to be useful in syphilitic complaints, in which it is given in the form of decoction, made with two drachms of the root to a pint of water. Schoepf states that it is purgative. The leaves were used during the revolutionary war as a substitute for tea. Dr. Hubbard recommends a strong infusion of the dried leaves and seeds, as a local application in aphthous affections of the mouth and fauces, and the sorethroat of scarlatina, and as an internal remedy in dysentery. (*Boston Med. and Surg. Journ.*, Sept. 30, 1835.) W.

CEDRON. The seeds of a tree growing in New Granada and Central America, and described by M. Planchon under the name of *Simaba Cedron*, in the *London Journal of Botany* (v. 566), from specimens sent by Mr. Wm. Purdie, curator of the Botanical Garden at Trinidad, to Sir Wm. J. Hooker. Mr. Purdie had received the first intimation of the value of this medicine from Dr. Cespedes, a physician of Bogota. The first account of it, however, which reached Europe appears to have been that of Dr. Luigi Rotellini, a physician of St. Domingo, who had previously resided in New Granada. It was published in an Italian journal so early as the year 1846. In France it appears to have been made known through M. Jamord, who received information of its effects from M. Herran, Chargé d'Affaires in France of the Republic of Costa Rica. The fullest account that we have seen of the plant and its product is from the pen of Sir Wm. J. Hooker. (See *Pharm. Journ.*, Jan. 1851, x. 344.)

Simaba Cedron belongs to the natural family of Simarubaceæ. It is a small tree, with an erect stem, not exceeding six inches in diameter, branching at top in an umbellate form, with large, glabrous, pinnate leaves, and pale-brown flowers, in long, branching racemes. The fruit is a large, solitary drupe, containing a single seed. The whole plant appears to be impregnated with a bitter principle, but it is the seed only that is used. A specimen of the dried fruit was kindly sent to the author from Cartago, in Costa Rica, by Dr. Guier, formerly of Philadelphia. It is light, of a yellowish-ash colour, flattish-ovate, with one edge convex and the other nearly straight, the convex outline terminating at each end in an obtuse point, of which that at the apex is most prominent. It is about two inches long, and sixteen lines in its greatest breadth. Within, the seed is loose and movable. The seed itself is about an inch and a half long, ten lines broad, and half an inch thick. It is convex on one side, flat or slightly concave on the other, and presents an oval scar near one extremity of the flat surface. It is hard and compact, but may be readily cut with a knife.

Cedron seed is inodorous, but of a pure and intensely bitter taste, not unlike that of quassia. It yields its virtues to water and alcohol. M. Lewry obtained from it a crystalline substance, intensely bitter, freely soluble in boiling water, and neutral to test paper, which he supposes to be the active principle, and proposes to name *cedrin*. He obtained it by first exhausting the cedron with ether, then treating it with alcohol, and crystallizing from the tincture. (*Journ. de Pharm.*, xix. 335.)

This medicine has long had great reputation in New Granada and Central America, as a remedy for the bite of serpents, being mentioned in the *History of the Buccaneers*, published in 1699, as useful for this purpose; and such continues to be the confidence of the natives in its virtues, that they have no fears of the poisonous bite of these reptiles, if provided with the antidote. It is also highly esteemed for the prevention of hydrophobia, and in the treatment of intermittent fever, spasm of the stomach and bowels, and dyspeptic affections. Dr. Guier informed us that he had seen it once apparently successful in curing the bite of a poisonous serpent, and had used it effectually in cholera morbus, colic, and neuralgia of the face. In the hands of Dr. J. B. Thompson, of London, it has proved useful in gout. (*Med. Times and Gaz.*, April, 1852.) Dr. S. S. Purple, of New York, has found it promptly effectual in a number of cases of intermittent fever, and believes it to possess valuable antiperiodic properties. (*N. Y. Journ. of Med.*, N. S., xiii. 173.) To us the medicine appears to be closely analogous to quassia, with which it is botanically allied. The dose used in Central America is one or two grains. M. Herran states that he had employed the remedy in eight cases of poisoning, and that his mode of using it was to administer five or six grains with a spoonful of brandy; and to dress the bite with the tincture. He had rarely occasion to repeat the dose to effect a cure. Dr. Rotellini says that it is poisonous in overdoses, and has occasioned death in the quantity of twenty-five or thirty grains. A vinegar has been prepared in London by macerating for seven days two

scruples of the cedron in an ounce of distilled vinegar. The dose is from twenty minims to a fluidrachm. (*Pharm. Journ.*, xii 63.) From the statements of Dr. Purple, it appears that the doses above stated are too small, and that, from any ordinary quantity, no fear of injurious consequences need be entertained. He gave from ten to thirty grains every four hours, and states that though, in very large doses, it may produce griping and diarrhœa, these effects are easily controlled. W.

CELASTRUS SCANDENS. *Climbing Staff-tree.* A climbing indigenous shrub, growing from Canada to Carolina, and said to possess emetic, diaphoretic, and narcotic properties. The bark is the part employed. It has been used in chronic affections of the liver and secondary syphilis. For a full description of the plant, see Darlington's *Flora Cestrica*, p. 149. Other species of Celastrus, growing in various parts of the world, have been employed in medicine, though with little reputation. W.

CENTAUREA BENEDICTA. *Blessed Thistle. Carduus benedictus. Cnicus benedictus.* (De Cand.) This is an annual herbaceous plant, the stem of which is about two feet high, branching towards the top, and furnished with long, elliptical, rough leaves, irregularly toothed, barbed with sharp points at their edges, of a bright-green colour on their upper surface, and whitish on the under. The lower leaves are deeply sinuated, and stand on footstalks; the upper are sessile, and in some measure decurrent. The flowers are yellow, and surrounded by an involucre of ten leaves, of which the five exterior are largest. The calyx is oval, woolly, and composed of several imbricated scales, terminated by rigid, pinnate, spinous points. The plant is a native of the South of Europe, and is cultivated in gardens in other parts of the world. It has become naturalized in the United States. The period of flowering is June, when its medicinal virtues are in greatest perfection. The leaves are the officinal portion. They should be gathered when the plant is in flower, quickly dried, and kept in a dry place. The herb has a feeble, unpleasant odour, and an intensely bitter taste, more disagreeable in the fresh than the dried plant. Water and alcohol extract its virtues. The infusion with cold water is a grateful bitter; the decoction is nauseous, and offensive to the stomach. The bitterness remains in the extract. The active constituents are volatile oil, and a peculiar principle for which the name of *cnicin* has been proposed. This is crystallizable, inodorous, very bitter, neither acid nor alkaline, scarcely soluble in cold water, more soluble in boiling water, and soluble in all proportions in alcohol. It consists of carbon, hydrogen, and oxygen, and is analogous to salicin in composition. In the dose of 4 or 5 grains, it is said often to vomit, and in that of 8 grains, to be useful in intermittent fevers. (*Ann. de Thérap.*, 1843, p. 206.) The blessed thistle may be so administered as to prove tonic, diaphoretic, or emetic. The cold infusion, made with half an ounce of the leaves to a pint of water, has been employed as a mild tonic in debility of the stomach. A stronger infusion, taken warm while the patient is confined to bed, produces copious perspiration. A still stronger infusion or decoction, taken in large draughts, provokes vomiting, and has been used to assist the operation of emetics. The herb, however, is at present little employed, as all its beneficial effects may be obtained from chamomile. The dose of the powder as a tonic is from a scruple to a drachm, that of the infusion two fluidounces.

Attention has recently been called to another species, *Carduus or Cnicus marianus*, which was of old used for the same purposes as the C. benedictus, under the impression that its seeds have valuable hæmostatic properties. Rademacher is stated to have found a decoction of the seeds of great use in hemorrhages, particularly when connected with diseased liver or spleen. Dr. Lobach considers no other remedy so efficacious in uterine hemorrhage and melæna. He has also found it useful in amenorrhœa when connected with derangement of the portal circulation. He gives the seeds in decoction, made in the proportion of two ounces to the pint of water, of which the dose is a tablespoonful every hour. (See *Am. Journ. of Med. Sci.*, April, 1859, p. 587.) W.

CENTAURY. *Common European Centaury. Centaurium.* This long-used remedy, which held a place in the Edinburgh Pharmacopœia even to its latest edition, has been omitted in the British Pharmacopœia. It consists of the herb, and more especially of the flowering heads of *Erythræa Centaurium* (Persoon), *Chironia Centaurium* (Willd. *Sp. Plant.* i. 1068). It is a small, annual herbaceous plant, rising about a foot in height, with a branching stem, which divides above into a dichotomous panicle, and bears opposite, sessile, ovate-lanceolate, smooth, and obtusely pointed leaves. The flowers are of a beautiful rose colour, standing without peduncles in the axils of the stems, with their calyx about half as long as the tube of the corolla. The plant grows wild in most parts of Europe, adorning the woods and pastures, towards the close of summer, with its delicate flowers.

The herb, though without odour, has a strong bitter taste, which it imparts to water and alcohol. The flowering summits are the officinal part. We have seen no satisfactory analysis of this plant. Among its constituents is a bitter extractive matter, for which the name of *centaurin* has been proposed. But it can scarcely be considered as a pure proximate principle. The fresh herb yields by distillation an odorous watery product, of sharp taste (*Geiger*, ii. 482), in which M. Méhu, a French pharmaceutist, has detected valerianic acid. The same chemist claims to have discovered a peculiar colourless crystallizable, non-nitrogenous substance, which he names *erythrocentaurin*. He obtained it by exhaust-

ing the tops with water, evaporating a portion of the water, allowing the residue to stand, separating the precipitated matter or apotheme, adding alcohol to the remaining liquid which now deposited a bitter substance, and, after the separation of this by decantation, evaporating the liquid to the consistence of syrup, and treating the residue with ether. The ethereal solution, upon evaporation, yielded the erythrocentaurin in crystals. These are needle-shaped, soluble in the ordinary menstrua, and possessed of the remarkable property of being strongly reddened by exposure to solar light, and reacquiring their colourless character upon being again dissolved and crystallized. The bitter substance before mentioned may be separated by menstrua into two, one soft and the other dry, the former of which it is that gives its strong smell to the distilled water. Besides these principles, M. Méhu found also in centaury a *wax-like substance*, and saline matter. (*Journ. de Pharm.*, xliii. 38.)

Medical Properties and Uses. The common centaury of Europe has tonic properties very closely resembling those of gentian, with which it is associated in the same natural family. It is employed on the other side of the Atlantic in dyspeptic complaints, and formerly had considerable reputation in the treatment of fever. It was one of the ingredients of the *Portland powder*. In the United States it has been superseded by *Sabbatia angularis*, or American centaury. The dose of the powder is from thirty grains to a drachm. Another species of Erythræa (*E. Chilensis*) possesses similar properties, and is employed to a considerable extent in Chili as a mild tonic. An elaborate account of it may be seen in the *Journal de Pharmacie* (3e sér., xxv. 434). The *E. acaulis*, which grows in great abundance in the territory of French Algiers, where it borders on the Sahara, yields a root, which, under the name of *rejagnou*, is much employed by the natives for dyeing yellow. (*Ibid.*, 4e sér., v. 87.) W.

CEPHALANTHUS OCCIDENTALIS. *Button-bush.* (*Gray's Manual*, p. 172.) A common indigenous shrub, which received both its generic title and common name from the arrangement of its flowers in dense spherical heads (*κεφαλή*, head, and *ἄνθος*, flower). It prefers moist places, as along streams or on the borders of swamps. Its bark is bitter, is said to be laxative as well as tonic, and has been given in periodical fevers, in decoction or infusion. W.

CHELIDONIUM MAJUS. *Celandine.* A perennial herbaceous plant, growing wild in this country, about old houses and in rocky places; supposed to have been introduced from Europe, where it is indigenous. It is one or two feet high, bears pinnate leaves and small peduncled umbels of yellow flowers, and, when wounded, emits a yellow, opaque juice. The whole plant is used. It has a faint unpleasant odour, and a bitter, acrid, durable taste, which is stronger in the roots than in the leaves. The odour is nearly lost by drying, but the taste remains. The yellow juice is bitter and exceedingly acrid, and when applied to the skin produces inflammation and even vesication. The plant, analyzed by MM. Chevallier and Lassaigne, afforded a bitter resinous substance of a deep-yellow colour; a kind of gum-resin of an orange-yellow colour, and bitter, nauseous taste; mucilage; albumen; and various saline substances, besides free malic acid and silica. Dr. Probst, of Heidelberg, afterwards found in it a peculiar acid denominated *chelidonic acid;* two alkaline principles, one of which forms neutral salts with the acids, and is called *chelerythrin* (*chelerythria*) in consequence of the intense redness of its salts, the other unites with but does not neutralize the acids, and is named *chelidonin* (*chelidonia*); and lastly a neuter, crystallizable, bitter principle, which from its yellow colour he calls *chelidoxanthin.* Chelerythrin appears to be an acrid narcotic poison. (*Annal. der Pharm.*, xxix. 113.) It has been shown by Dr. James Schiels, of St. Louis, to be identical with *sanguinarina*, and may be prepared in the same manner. (See *Sanguinaria*, page 769.) Zwenger has lately isolated another acid, which he names *chelidoninic acid.* (See a paper by Mr. J. M. Maisch, in the *Am. Journ. of Pharm.*, Jan. 1861, p. 7.)

Celandine is an acrid purgative, possessed also of diuretic, and perhaps diaphoretic and expectorant properties. In overdoses, it produces unpleasant effects, and is by some considered poisonous. By the ancients it was much esteemed as a remedy in jaundice; and it has been found useful in the same complaint by some modern physicians. It was the chief ingredient of the old *decoctum ad ictericos* of the Edinburgh Pharmacopœia. It has been given also in other complaints, especially those of a scrofulous character, affecting the mesenteric and lymphatic glands, the skin, and the eyes. The yellow juice is often applied to corns and warts, which it destroys by stimulating them beyond their vital powers, and is said to be very useful in eczema, urticaria, and other itching eruptions. The fresh herb is also applied locally about the pelvis, with asserted benefit, in amenorrhœa, and is much used in the South of Europe as a vulnerary. The dose of the dried root or herb is from thirty grains to a drachm, that of the fresh root one or two drachms; and the same quantity may be given in infusion. The watery extract and expressed juice have also been employed. The dose of the former is from five to ten grains, of the latter from ten to twenty drops, to be gradually increased. W.

CHELONE GLABRA. *Snake-head. Turtle-head.* (*Gray's Manual*, p. 285.) This is a very common indigenous, perennial, herbaceous plant, a foot or two in height, readily distinguished by its conspicuous closely clustered flowers, the shape of which, from their

resemblance to the head of a snake or tortoise, has given origin both to the common and scientific names of the plant. It prefers low wet places. The leaves have a bitter taste, and are said to be tonic and aperient, with a supposed peculiar action on the liver. The decoction, made in the proportion of two ounces of the fresh herb to the pint, may be given in the dose of one or two fluidounces. W.

CHELTENHAM SALT, ARTIFICAL. Several artificial mixtures have been prepared, professing to be exact imitations of the saline ingredients in the chalybeate Cheltenham water; but the only ones which appear worthy of confidence are those prepared by Robert Alsop, chemist, of London, and W. Hodgson, jun., druggist, of this city. The composition of the natural Cheltenham chalybeate is given at *page* 140. The imitation of Mr. Alsop, as analyzed by Dr. Faraday, contains the same solid and gaseous constituents as the natural water, except the sulphate of lime, which is very properly omitted; and in the same proportions precisely, with the exception that there is about twice as much free carbonic acid in the artificial preparation. The iron is present in the state of protoxide, and is immediately dissolved by the free carbonic acid, upon adding a sufficient quantity of water. The carbonic acid probably exists in a free state in a dry mixture; as there is no obvious agent present to cause it to be disengaged in the mere act of solution.

Mr. Alsop's artificial mixture is in the form of a powder, nearly white, possessing a saline and slightly ferruginous taste. It forms a good combination, in which the aperient property of the salts present is combined with the tonic virtue of the iron. It is considered to be useful in glandular obstructions, especially of the liver, and in scrofulous affections, attended with feeble digestion, sluggish bowels, and pallidness of skin. It is employed, also, with advantage in sick headache, habitual costiveness, and hemorrhoids. The dose is a teaspoonful, quickly dissolved by brisk stirring in half a pint of cold water, and swallowed immediately, before the iron has time to separate in an insoluble state. This quantity may be taken in the morning, fasting, and repeated once or twice after an interval of twenty minutes, or in the course of the day. To obtain its full tonic and alterative effects, it should be persevered with for a month or six weeks. The artificial Cheltenham salt of Mr. Hodgson is identical with that of Mr. Alsop, and may be used with entire confidence for all the purposes to which the latter is applied. B.

CHLORIDE OF ARSENIC, SOLUTION OF. *Liquor Arsenici Chloridi. De Valangin's Arsenical Solution.* The following formula was given for this preparation in the late London Pharmacopœia. "Take of Arsenious Acid, broken into small pieces, *half a drachm;* Hydrochloric Acid *a fluidrachm and a half* [Imperial measure]; Distilled Water *a pint* [Imp. meas.]. Boil the Arsenious Acid with the Hydrochloric Acid, mixed with a fluidounce [Imp. meas.] of the Water, until it is dissolved; then add sufficient Water to make the solution accurately fill the measure of a pint [Imp. meas.]." This is an imitation of De Valangin's arsenical solution, called by the inventor, who was a practitioner in London, *solutio solventis mineralis.* It was originally made by subliming three parts of arsenious acid with eight of common salt, and dissolving the product in a determinate quantity of dilute muriatic acid. The sublimation directed by De Valangin with common salt had no effect on the arsenious acid; and, accordingly, his preparation may be considered to have been a solution of arsenious acid in muriatic acid, becoming terchloride of arsenic by the mutual decomposition of the acids. In the London formula thirty grains of arsenious acid were dissolved in twenty Imperial fluidounces of the menstruum, that being the measure to which the preparation is ultimately brought. Hence each fluidounce contains a quantity of terchloride equivalent to a grain and a half of arsenious acid. Terchloride of arsenic is a colourless anhydrous liquid of the sp. gr. 2·18. It is strongly acid to litmus, completely soluble in alcohol and ether, and possesses the power of dissolving a considerable proportion of arsenious acid. (Dr. Penny and Mr. W. Wallace, *Philos. Mag.*, xli. 365.)

Medical Properties. This arsenical solution has considerable reputation in London as an alterative. It is chiefly employed in the treatment of chorea and lepra vulgaris. Dr. Farre, of London, states, as the result of his observation, that it effectually cures the worst forms of chorea. (Pereira, *Mat. Med.*, 3d ed., p. 670.) The late Dr. Pereira, who used this solution on numerous occasions, found it efficacious in the treatment of chorea and lepra, but was not convinced of its superiority to Fowler's solution. It is said to be less apt to disturb the stomach; but it must be recollected that De Valangin's solution is only three-eighths as strong as that of Fowler, and yet is not given in a larger dose. The average dose is five drops three times a day. Dr. Farre begins with three drops three times a day, increasing one drop each day, until the dose reaches ten drops three times daily. Whenever the stomach becomes disordered, the medicine should be suspended; and, when renewed, it must be given in the original dose. Dr. Fuller, of London, praises this solution as a remedy in rheumatic gout, if the urine be clear and of low sp. gr. In such cases he gives it in the large dose of from ten to twenty drops, either alone or combined with cinchona. If mineral acids are indicated, muriatic acid is added. B.

This article was omitted in the original British Pharmacopœia, but was introduced in a modified form in the late edition. (See *Liquor Arsenici Hydrochloricus*, Br., in *Part* II. of this work.) The present British preparation has nearly three times the strength of the Liquor Arsenici Chloridi of the late London Pharmacopœia. W.

CHLORIDE OF BROMINE. *Brominii Chloridum.* This chloride is prepared by passing chlorine gas through bromine, and condensing the vapours which form by a freezing mixture. It is a reddish-yellow, very mobile and volatile liquid, emitting dark yellow fumes, which have a very powerful odour, and cause a flow of tears. Its taste is hot and unpleasant. Chloride of bromine is used by Prof. Landolfi, of Naples, in the treatment of cancer and malignant tumours, both internally and as an ingredient in his caustic. For the composition of the caustic, and his formula for administering the chloride of bromine, see *page* 181–2, and the article on *Zinci Chloridum* in *Part* II. B.

CHLORIDE OF MAGNESIUM. *Magnesii Chloridum. Muriate of Magnesia.* When a concentrated solution of this salt is evaporated to dryness, it is partially decomposed into magnesia and muriatic acid, the latter being evolved. By a careful evaporation, stopping it so soon as the vapour begins to redden litmus paper, the chloride may be obtained in the state of a fused hydrate, having the composition $MgCl,6HO$. (Casaseca, *Chem. Gaz.*, Oct. 15, 1853, p. 384.) The physiological action of this bitter and very deliquescent salt is the subject of a memoir by Dr. Lebert. He finds it to act mildly and favourably as a purgative, producing a flow of bile, and an increase of appetite. On account of its extreme deliquescence, he recommends it in the liquid form, prepared by dissolving the salt in its weight of water. Of this solution he gives an ounce sufficiently diluted to an adult, and half an ounce to a child from 10 to 14 years of age. (*Arch. Gén.*, 4e sér., iii. 448.) B.

CHLORIDE OF MERCURY AND QUINIA. *Hydrargyri et Quiniæ Chloridum.* This compound has been prepared by Mr. McDermott, of Dublin, by uniting chemically corrosive sublimate with quinia. The corrosive sublimate was found to be reduced to the state of calomel; and, hence, it may be inferred that half the chlorine of the former united with the quinia. This preparation has been found useful in the treatment of obstinate skin diseases, given in the dose of a grain two or three times a day. B.

CHLORIDE OF POTASSA, SOLUTION OF. *Liquor Potassæ Chlorinatæ. Javelle's Water. Eau de Javelle.* This is prepared from carbonate of potassa precisely as the solution of chlorinated soda from carbonate of soda, and probably has an analogous composition. (See *Liquor Sodæ Chlorinatæ.*) It is employed for taking out fruit stains, &c. from linen. B.

CHLORIDE OF SILVER. *Argenti Chloridum.* This has been already referred to as being inevitably formed when nitrate of silver is given internally. (See *page* 1047.) It is rgadily prepared by adding a solution of common salt to one of nitrate of silver, as long as it produces a precipitate. As first thrown down it is a white curdy substance, but it soon becomes discoloured when exposed to the light. It is decomposed by solutions of the caustic alkalies, which convert it into oxide, but not by their carbonates. After the formation of the oxide in this way, the addition of sugar reduces it, and revives the silver. (*Levol.*) Chloride of silver has been used, rubbed on the tongue, in syphilis, and internally in epilepsy, chronic dysentery and diarrhœa, and other diseases in which nitrate of silver has been given. The dose is from one to three grains or more, four or five times a day. Dr. Perry administered it at the Philadelphia Hospital, Blockley, in chronic dysentery, with the immediate effect of diminishing the number of stools. The crystallized *ammonio-chloride of silver* has been given in syphilitic affections, in the dose of the fourteenth of a grain. It is formed by saturating solution of ammonia, by the aid of heat, with chloride of silver, and allowing the liquid to cool in a stopped bottle. It crystallizes in cubes, and is very liable to decomposition. B.

CHLORIDE OF TIN. This chloride, which may be made by heating tin and muriatic acid together, has recently been recommended by M. Mallez, for local application in cases of gonorrhœa and purulent discharges from the vagina, as having a direct curative agency in these affections. He injects daily, in divided portions, a solution containing half a drachm of the salt in three fluidounces of distilled water. He has employed the same solution with complete success in a case of obstinate purulent otitis, which had resisted all the aurists. (*Ann. de Thérap.*, 1868, p. 175.) W.

CHLORINATED ANÆSTHETIC COMPOUNDS. By the mutual action of chlorine and olefiant gas, an oily liquid is obtained, discovered by the associated Dutch chemists, and called *Dutch liquid.* The empirical formula of this compound is $C_4H_4Cl_2$, which makes it the *bichloride of ethylen;* the rational formula is C_4H_3Cl,HCl. When it is acted on by an alcoholic solution of potassa, muriatic acid is separated by the formation of chloride of potassium, and a compound represented by C_4H_3Cl is set free. By the action of additional chlorine, the Dutch liquid is susceptible of having each equivalent of hydrogen successively replaced by one of chlorine, forming four new compounds; namely, $C_4H_2Cl_2,HCl$ — C_4HCl_3, HCl — C_4Cl_4,HCl — C_4Cl_6. The last compound here is evidently a 6–4 chloride of carbon; and the others are called by Regnault, in allusion to the replacing chlorine, without noting the disappearing hydrogen, monochlorinated, bichlorinated, and trichlorinated Dutch liquid. The Dutch liquid has been tried as an anæsthetic by Prof. Simpson and Mr. Nunnely. Prof. Simpson was not satisfied with its effects; but Mr. Nunnely, having administered it frequently in practice, found it perfectly agreeable in every respect. Its use, he alleges, is not attended by the troublesome excitement produced by

ether, or by the tendency to collapse caused by chloroform. Two forms of Dutch liquid have been recently experimented with by Dr. Aran, of Paris; and one of them furnished satisfactory clinical results. The liquid which gave favourable results has been ascertained by Mialhe and Flourens to be the monochlorinated Dutch liquid; but its cost proved to be too high to allow of its general use as a therapeutic agent. In consequence of this objection to the monochlorinated liquid, Mialhe and Flourens were induced to search for a substitute in the corresponding compound of a parallel series of ethers, formed by the action of chlorine on muriatic ether. When muriatic ether (C_4H_5Cl) is acted on by successive portions of chlorine, the hydrogen is replaced by the latter, equivalent for equivalent, and there are formed the five following compounds: $C_4H_4Cl_2$ — $C_4H_3Cl_3$ — $C_4H_2Cl_4$ — C_4HCl_5 — C_4Cl_6. Of this series, the first member is isomeric with the Dutch liquid; the second, third, and fourth with the mono- bi- and trichlorinated Dutch liquid, and the fifth is the 6-4 chloride of carbon, the terminating compound of the other series. The first member, though identical with the Dutch liquid in elementary composition, and having a vapour of the same density, has, nevertheless, a lower boiling point, and is different in chemical properties. Thus, it is not decomposed by an alcoholic solution of potassa, as the Dutch liquid is, and is not acted on by potassium, while the Dutch liquid is immediately attacked by it. These facts show that the atomic constitution of these two substances must be different. In like manner the second, third, and fourth members of this series are different in chemical properties from their isomeric representatives in the Dutch liquid series. In denoting the different degrees of chlorination of the muriatic ether series, Regnault indicates merely (as in the Dutch liquid series) the number of eqs. of chlorine supposed to replace hydrogen. Accordingly, he calls the first member of the series monochlorinated muriatic ether, corresponding to the Dutch liquid; and the second, third, and fourth, bi-tri- and quadrichlorinated muriatic ethers, corresponding to the mono- bi- and trichlorinated Dutch liquids. This confusion of nomenclature arises from the fact that the replacement by chlorine sets out from five eqs. of hydrogen in the muriatic ether series, and from four eqs. in the Dutch liquid series.

From the explanations above given, it will be understood that the compound of the muriatic ether series, corresponding to the monochlorinated Dutch liquid, is the bichlorinated muriatic ether. This compound proved too volatile to act advantageously as a local anæsthetic. The tri- and quadrichlorinated ethers are denser and less volatile, and acted more favourably. The conclusion arrived at by Mialhe and Flourens appears to be that the four chlorinated muriatic ethers all possess anæsthetic properties; and, as it would be difficult to separate them, they propose the use of the mixed ethers, consisting principally of the tri- and quadrichlorinated compounds, as an anæsthetic, under the indefinite name of chlorinated muriatic ether.

Chlorinated muriatic ether (*chlorinated chlorohydric ether*) is a colourless, very mobile, neuter liquid, having an aromatic ethereal odour, and hot saccharine taste. It is sparingly soluble in water, but readily soluble in alcohol, ether, and most of the fixed and volatile oils. It is not inflammable, in which respect it agrees with chloroform. Being a mixture of different liquids, its sp. gr. is not uniform. Its boiling point varies from 230° to 266°. According to the experiments of Flourens, it has a similar action to chloroform, the most important of the chlorinated anæsthetics. (See *Chloroformum*.) Its local action is that of a powerful sedative. (B. Cucuel, *Ann. de Thérap.*, 1853, 102.) B.

Within a very short time various other chlorinated compounds have been brought forward as having anæsthetic virtues, of which those most deserving of attention are probably the *bichloride of methyl*, *bichloride of carbon*, and a preparation called *chloral*, formed by the action of chlorine on alcohol. It will be more convenient to consider these under the general name at the head of this article, than to scatter them here and there, according to the position of their titles in an alphabetical catalogue.

Bichloride of Methylen. *Chloromethyl.* This was introduced into notice by Dr. B. W. Richardson, of London. It may be prepared by exposing to sunshine, in a glass globe, chlorine and gaseous chloride of methyl. The globe is provided with two lateral apertures for the admission of the gases, and below with an open neck, which communicates with one of the tubulures of a Woulfe's bottle, of which the other tubulure communicates by a bent tube with a second Woulfe's bottle, and this by another bent tube with a flask. The second bottle is surrounded with ice, and the flask immersed in a freezing mixture, to condense the volatile products. The bichloride condenses in the flask in a pure state, while the contents of the two Woulfe's bottles consist chiefly of chloroform. (*Gmelin*, vii. 288.)

The chloride of methyl may be made for the purpose by heating together 1 part of wood-spirit, 2 parts of common salt, and 3 of sulphuric acid, and collecting the evolved gas over water, which retains the impurities. Chloride of methyl is a colourless gas, having an ethereal odour and a sweet taste. (*Gmelin.*) Dr. Richardson found it to possess anæsthetic properties, but to be less manageable than the bichloride of methylen.

Bichloride of methylen is a colourless liquid, of an odour analogous to that of chloroform, of the sp. gr. 1·344, and the boiling point 88° F. The density of its vapour is 3·012 (*Gmelin*), 2·937 (*Richardson*). It consists of one eq. of methylen and two of chlorine, and its formula is $C_2H_2Cl_2$. In its preparation, chlorine appears to take one eq. of hydrogen

from the chloride of methyl and to give it an eq. of chlorine; thus converting C_2H_3Cl (chloride of methyl) into $C_2H_2Cl_2$ (bichloride of methylen). The vapour of the bichloride does not, like that of chloroform, extinguish the flame of a taper, but itself takes fire, burning with a brilliant flame, and yielding, as the result of its combustion, carbonic and muriatic acids. Bichloride of methylen mixes readily with absolute ether, and, as the boiling points of the two approach nearly, they volatilize evenly and equably. It is neutral to test paper; and an acid reaction in any specimen would be an evidence of the presence of muriatic acid, and should preclude its use as a respiratory anæsthetic. To prevent the generation of the acid, the liquid should be kept carefully secluded from the sunlight.

Dr. Richardson, in his experiments with animals, found it, when inhaled, to produce insensibility without previous excitement, and the insensibility, when produced, continues longer without an additional administration than that caused by other anæsthetics. Like the others, it may be made to destroy life; but it has this advantage over them, that, after death, the muscular irritability remains longer; and consequently the chances are greater of a restoration of the vital functions by the means employed. The condition in which the heart and lungs are left after death from it is favourable to resuscitation. On the whole, Dr. Richardson gives, as the result of his experiments both with the inferior animals and man, the following conclusions. 1. The bichloride produces as deep insensibility as chloroform. 2. Its action is rather more rapid; but more is required to produce the desired effect, in the proportion of about six to four. 3. It produces a less prolonged second degree of narcotism than other anæsthetics. 4. The narcotism, when induced, is very prolonged, and may be reproduced with great ease. 5. It acts equably through the nervous centres of respiration and circulation; producing no break in the natural relation between these functions. 6. It rapidly escapes from the system, so that recovery is sudden when it begins. 7. It sometimes, like ether and chloroform, causes vomiting. 8. When it kills, it is by equally paralyzing the circulation and respiration. 9. It interferes with muscular irritability less, probably, than any other anæsthetic. 10. It combines with ether and chloroform in all proportions. It has been tried in several cases of severe surgical operations, and with results thus far altogether satisfactory. The quantity used averaged about a drachm every five minutes. (Dr. B. W. Richardson, *Med. Times and Gaz.*, Oct. and Nov. 1867, pp. 423 and 479.)

Under the recommendation of Dr. Richardson, the bichloride has been used by several others, with satisfactory results. Dr. A. Russell Strachan, of New York, has published an account of his experience with it in the *Medical Record* (March 2, 1868, p. 22). Trying it first on himself, he inhaled it from lint upon which about a drachm had been poured, and at once began to experience pleasant and extremely composing sensations, soon followed by an "irresistible tendency to somnolence," without any of the disagreeable sensations in the head usually attendant on the inhalation of ether and chloroform. Feeling that he would soon be beyond his own control, he poured about three drachms more of the liquid on the lint, and continued to inhale until entirely unconscious. About half an hour from the beginning, he suddenly reacquired consciousness, feeling perfectly well and fit to attend to his affairs. There was no nausea, oppression, or other unpleasant feeling; and nothing remained to remind him of the experiment but a somewhat disagreeable flavour in the mouth and throat. Encouraged by the results of this trial, he used the anæsthetic afterwards in one surgical and in one obstetrical case with complete success; the patients having been speedily narcotized, in one instance in three minutes, afterwards kept insensible as long as was needful, and in the end suddenly awaking, with nothing but comfortable sensations. In the surgical case two drachms were at first administered on a folded napkin, four minutes afterwards another drachm, and, in the course of the operation, which lasted nearly three-quarters of an hour, somewhat more than an ounce and a half. In the obstetrical case a drachm and a half of the bichloride was sufficient to produce unconsciousness in three minutes; which was afterwards maintained without difficulty, so far as was necessary, until the birth of the child.

The anæsthetic has been used successfully also in Germany. M. Hollænder used it six times in the extraction of teeth, and in only one instance was it followed by heaviness of head and vomiting. In the five others, a drachm was sufficient to produce anæsthesia, which continued for from 15 to 20 minutes, and then suddenly ceased, without unpleasant symptoms. M. Nussbaum has used the new anæsthetic repeatedly; and has observed the same three stages of its action as in chloroform, only that the awakening is more agreeable and after a longer period of unconsciousness. In several patients the bichloride acted almost instantaneously. (*Arch. Gén.*, Mars, 1868, p. 362.)

Several surgeons in London have employed the new agent, and among others Dr. Spencer Wells, who proposed for it the name of *chlormethyl* (*Med. Record*, ut supra). Mr. Peter Marshall and others, after repeated trial with the bichloride and chloroform, are disposed to give the preference to the former; and the only objection to its general use appears to be its great costliness. (*Lancet*, Feb. 22, 1868, p. 271.)

On the whole it would seem, from the result of experience thus far, that, in reference to the convenience of its administration, bichloride of methylen enjoys at least an equal superiority with chloroform over ether; whilst, as regards the safety of its use, should

equal immunity from fatal results continue to attend its operation as heretofore, there can be no doubt of its superior claims over an anæsthetic which causes death in at least one out of every 1500 cases in which it is used.

Since the above was sent to press, our attention has been called to a case in which death occurred from the use of this anæsthetic at the Charing Cross Hospital, London. The patient was a man 39 years of age, affected with cancer of the face, and weakened by hemorrhage, but not extremely so. A fluidrachm of bichloride of methylen was gradually administered, and at the end of three minutes half a drachm more, when symptoms of exhaustion rapidly came on, and death took place apparently from pure paralysis of the heart. The occurrence of this case forbids the hope which had been indulged that a safe anæsthetic had been found as a substitute for chloroform. (*British Med. Journ.*, Oct. 23, 1869.)

In relation to its exhibition, the following observations are worthy of record. The vapour is agreeable, and patients generally prefer it to chloroform. Dr. Richardson uses for its administration a hollow cone of some absorbent material. The deepest narcotism may be induced by three drachms; in short operations, one or two drachms are sufficient. Complete anæsthesia can be induced in three minutes. A sign peculiar to its operation is the occurrence of double strabismus. For its administration a temperature from 60° to 80° F. should be preferred. (*Med. Times and Gaz.*, July, 1868, p. 109.)

The bichloride of methylen may be used in the dose of from ten to thirty minims, or be given in dilute spirit. (*Lancet*, ut supra.)

Bichloride of Carbon. *Tetrachloride of Carbon. Chlorocarbon.* The substance to which these several names have been attached, though discovered by Regnault so early as 1839, did not come into general notice until December, 1865, when it was suggested as an anæsthetic by Prof. Simpson, now Sir J. Y. Simpson, of Edinburgh, in a paper published in the *Med. Times and Gaz.* (Dec. 1865). It appears, however, that it had been previously used as an anæsthetic by Dr. A. E. Sansom and Dr. John Harley, who experimented with it in 1864, and recorded their experience in Dr. Sansom's work on Chloroform, published in May, 1865. (*B. and F. Med.-chir. Rev.*, Oct. 1867, p. 551.) To procure it, dry chlorine is passed first through a bottle containing sulphuret of carbon, and then through a porcelain tube, filled with pieces of porcelain, and kept at a bright-red heat. The vapours are condensed in a cooled receiver, forming a yellowish-red liquid, which is a mixture of bichloride of carbon, and chloride of sulphur. The chloride of sulphur is removed by slowly adding the liquid to an excess of ley of potash or milk of lime; the mixture being set aside, and agitated from time to time till the sulphur compound is decomposed, and then distilled. Bichloride of carbon passes over, sometimes mixed with a portion of sulphuret of carbon which has escaped decomposition, but which may be separated by occasionally bringing the mixture into contact with ley of potash. There are other modes of preparing it, which will be found in *Gmelin's Handbook* (vii. 356). By one of these, chloroform is made to yield it by the substitution of an eq. of chlorine for one of hydrogen; thus C_2H,Cl_3 (chloroform) becomes C_2Cl_4 (bichloride of carbon).

Bichloride of carbon is a transparent colourless liquid, of the sp. gr 1·599 (Regnault), boiling at 172° F., with a vapour density 5·33, and an agreeable aromatic flavour. In composition it is a bichloride (C_2Cl_4 or $C_2Cl_2Cl_2$); but, according to the new notation, which doubles the weight of carbon, it is a tetrachloride (CCl_4 or CCl_2Cl_2). Sir J. Y. Simpson, to obviate this uncertainty of nomenclature, proposes *Chlorocarbon* as a medical or pharmaceutical title, sufficiently expressive without ambiguity.

Effects and Uses. Dr. P. Smith describes its effects as follows. About half a drachm on a handkerchief was inhaled. The vapours had an agreeable odour, not unlike that of the quince; a sense of coolness in the fauces was experienced similar to that caused by oil of peppermint; and this was followed by a feeling of warmth on the surface of the body generally. A feeling of calmness and comfort succeeded, which continued until the end of the day; and the sleep at night was sounder than usual. Similar effects were afterwards obtained in greater degree upon a repetition of the experiment with an increased dose. Rapid anæsthetic effects were produced, followed, in about two minutes, by calm sleep, and in about a minute longer, by a complete return of consciousness. The bichloride was then tried on animals, with the result, in small doses, of causing entire loss of power and consciousness, from which they soon recovered entirely; but larger doses occasioned death; the animal becoming first unconscious, then gradually ceasing to respire, and dying in eight minutes. The heart was not felt to beat after the breath had ceased. Similar experiments were performed by Dr. John Harley with essentially similar results. From numerous trials afterwards made on human subjects in various morbid conditions, the conclusion was arrived at, that the bichloride of carbon may be usefully employed, by inhalation, for the relief of pain, especially headache, tic douloureux, toothache, the sufferings of dysmenorrhœa, &c., that it will be a valuable agent for mitigating the pains of labour, and that its local use may prove serviceable for similar purposes. In the majority of instances there was no supervening nausea or vomiting; and no unpleasant effect on the skin or mucous membrane. It is pleasanter to inhale than chloroform, and produces anæsthesia with less previous muscular spasm. Though slower in escaping from the system, yet its effects on perception are more evanescent, and consciousness

usual y returns in a few moments after the cessation of respiration. Pain, however, and voluntary muscular power, may be suspended without the complete loss of consciousness. Like all anæsthetics, it may destroy life if recklessly used. (*Lancet*, June 1, 8, and 29, 1867, pp. 661, 692, and 791.)

Sir J. Y. Simpson says, of this anæsthetic, that the effects of its vapour approach nearer to those of chloroform than any other similar agent. Its primary effects are very analogous to those of chloroform, but it takes a longer time to produce the same degree of anæsthesia, and generally longer to recover from it. Its depressing influence, however, on the heart, he observes, is far greater, and, consequently, its employment far more dangerous. It is less irritant to the skin, and, therefore, may sometimes be preferable as a local anæsthetic. The injection of its vapour into the rectum is also less irritating. Its vapour, applied to the eye by sprinkling a few drops on the hand, is one of the most effectual means of relieving some forms of conjunctivitis, ulceration of the cornea, photophobia, &c. Injected subcutaneously, in the dose of 10 to 20 drops, it relieved pains in the walls of the chest and abdomen, without subsequent nausea. Internally, Sir James tried it only in small doses in gastrodynia, in which it had the same effects as chloroform. (*Med. Times and Gaz.*, Dec. 1865, p. 651.)

Chloral. *Hydrate of Chloral.* Though discovered thirty years since by Liebig, this compound has but recently attracted attention as an anæsthetic agent, having been first brought before the Medical Society of Berlin on the 2d of June last (A. D. 1869), by Dr. Otto Liebreich of that city. It results from the action of chlorine on alcohol, the latter of which gives up five of its six eqs. of hydrogen to the former, producing five eqs. of muriatic acid, and combines in their place with three eqs. of the chlorine, to form the substance in question. The change probably takes place in the following manner. The alcohol ($C_4H_6O_2$), by the loss of two eqs. of hydrogen, becomes aldehyd ($C_4H_4O_2$); of which the radical acetyl (C_4H_3) gives up its three eqs. of hydrogen and takes three eqs. of chlorine, forming a new radical (C_4Cl_3); and this, combining with one eq. of the oxygen, and with the remaining eq. each of hydrogen and oxygen, form chloral (C_4Cl_3O+HO), or a variety of aldehyd in which the three eqs. of hydrogen of the radical are replaced by three eqs. of chlorine. Anhydrous chloral is an oily pungent fluid, the vapour of which is very irritating to the eyes. On standing it undergoes decomposition, and ultimately becomes solid. It combines with water to form a crystalline hydrate, which is very soluble in water. This hydrate is not affected by concentrated sulphuric acid, but is decomposed by the alkalies, causing the production of chloroform, which may thus be obtained in a very pure state. Formiate of the alkali used is also generated. It has been inferred by Dr. Liebreich that, when taken into the circulation, where it meets with soda, it undergoes decomposition, one of the results of which is the formation of chloroform; so that it is not the chloral itself, but the chloroform which really operates; and the fact is that the symptoms following the exhibition of chloral are closely similar to those which characterize the action of chloroform.

As pure chloral readily undergoes decomposition, the comparatively stable *hydrate* is the form in which the medicine is best kept for use. A small dose given by Dr. Liebreich to a kitten produced gentle sleep, and there was only wanting the preliminary excitation of the chloroformic anæsthesia to identify its operation with that of chloroform. He produced a hypnosis of nine hours' duration, by the subcutaneous administration of 0·5 gramme of the hydrated chloral, equivalent to 0·35 of anhydrous chloral, and 0·29 of chloroform. Frogs were similarly affected. First there was unconsciousness, reflex excitability remaining; then came a loss of the latter, and finally a return to the natural state. A fatal dose left the whole heart gorged with blood, having suffered a complete paralysis. The author was convinced, by numerous experiments, that chloral acts, like chloroform, first on the ganglionic cells of the brain, then on those of the spinal marrow, and finally, in fatal cases, on those of the heart. The agent was then tried on man. At first very small doses were given. No local irritation was caused by them. A dose of 1·35 grammes of the hydrate, given subcutaneously, caused a sleep which lasted five hours. In a case of melancholia, 3·5 grammes, in a wineglass of water, produced a sleep of sixteen hours. In a case of very painful inflammation of the wrist, 2·5 grammes caused somnolence with partial anæsthesia, so that the patient could bear a tight bandage. In every instance the sleep was normal, and came on five minutes after the administration of the dose. (*Wiener Medizinisch. Wochenschrift*, Aug. 14.)

In the *Allgemein. Medizin. Cent. Zeitung*, of September, is an account of a case of delirium tremens treated by Dr. Langenbeck, in which, after full doses of morphia had been of no avail, 4·5 grammes (about 70 grains) of hydrated chloral were given by the stomach, dissolved in water; and in twenty-three minutes afterwards another gramme was injected subcutaneously. In five minutes the patient went to sleep, and continued to sleep soundly and naturally from the afternoon until morning; and awoke quite well.

From the above statements, derived from the original German sources, it would appear that we have at last an excellent anodyne and soporific, equal in these respects to chloroform, without the unpleasant and often inconvenient local irritation produced by that remedy. Another advantage is that, as it is administered by the stomach or subcutaneously, it is in great measure free from the danger incurred by the inhalation of chloroform.

Dr. T. Spencer Wells, of London, gave thirty grains of the hydrate of chloral to a lady

who had suffered long from a severe and intractable sciatica, with the effect of giving the patient a night of perfectly tranquil sleep, such as she had not enjoyed from the commencement of her illness. The same dose was repeated, with the same effect; and, though it became necessary afterwards to increase the dose to 45 grains to ensure satisfactory results, yet the effect was always obtained, except in a single instance. She complained, however, of headache in the mornings. (*Med. Times and Gaz.*, Sept. 1869, p. 346.)

Dr. B. W. Richardson, of London, has also recently experimented with hydrate of chloral, both on men and the lower animals, with results essentially the same as those of Dr. Liebreich; but, in his experiments on birds, he found this anæsthetic to produce vomiting in the same manner and degree as chloroform. (*Ibid.*, Sept. 1869, p. 291.) W.

CHLORINATED MAGNESIA, SOLUTION OF. Mr. Robert E. Fairthorne has suggested this solution as a substitute for solution of chlorinated soda or chlorinated lime, in cases in which, whether internally or externally, the influence of the chlorine is especially required, and in which the irritant or corrosive quality of the soda or lime might be contraindicated. He proposes the following formula. "Dissolve eight ounces of sulphate of magnesia in two pints of water. Triturate in a mortar four ounces and one drachm of chlorinated lime with an equal amount of the same fluid. Mix the solutions, and agitate occasionally. After standing twelve hours, pour off the supernatant liquid." Mr. Fairthorne found that each ounce of the solution contains somewhat less than nine grains of magnesia. (*Am. Journ. of Pharm.*, Jan. 1868, p. 70.) W.

CHROME. *Chromium.* As it has been customary, in this work, to notice more or less fully the metals of which one or more compounds are officinal, even though the metal may not hold the same position, it is proper to give a brief notice in this place of the metal chrome, of which two compounds, chromic acid and bichromate of potassa, are contained in the Materia Medica Catalogue of our Pharmacopœia. Chrome was discovered by Vaquelin in 1797. Its most common ore is the chromite of iron, consisting of protoxide of iron and sesquioxide of chromium. This is not an abundant mineral; and one of the most copious sources of it is in the chrome mines of south-eastern Pennsylvania. Chrome is obtained by igniting its oxide intensely in contact with charcoal. It is a brittle metal, of a grayish-white colour like platinum, with some lustre, and very hard, so that it scratches glass. Its sp. gr. is 5·9, equivalent 26·3, and symbol Cr. It does not change by exposure to the air, and is with difficulty attacked by the acids. It forms with oxygen five compounds: 1. the protoxide (CrO), 2. the sesquioxide (Cr_2O_3), 3. chromic acid (CrO_3). Of the two others, one may be considered as a compound of the protoxide and sesquioxide (CrO,Cr_2O_3), and the other, called *perchromic acid*, is said to consist of two eqs. of chrome and seven of oxygen (Cr_2O_7). Chrome combines with chlorine in two proportions, forming the protochloride and sesquichloride. The chief value of chrome in the arts is as the source of bichromate of potassa, extensively used in dyeing and valuable for the facility with which it parts with oxygen, and as the base of certain beautiful pigments. W.

CHROME YELLOW. This is the neutral chromate of lead, prepared by precipitating a solution of the nitrate of lead with chromate of potassa. It is of a beautiful lemon-yellow colour. The subchromate of lead, consisting of one eq. of acid and two eqs. of base, is of a red colour, and is sometimes used as a pigment. *Chrome green* is a mixture of chrome yellow and Prussian blue. W.

CICHORIUM INTYBUS. *Chicory. Succory.* A perennial herbaceous plant, indigenous in Europe, but naturalized in this country, where it grows in fields, and in roads along the fences, in neighbourhoods which have been long settled. It is one or two feet high, with large, compound, beautifully blue flowers, which appear in July and August, and serve to distinguish the plant at first sight. The whole plant has a bitter taste, without acrimony, or any very peculiar flavour. The taste is strongest in the root, and weakest in the flowers. The leaves, when young and tender, are said to be sometimes eaten as salad in Europe. Succory is gently tonic without being irritating, and is considered by some authors as aperient and deobstruent. It is said to be useful, if freely taken, in hepatic congestion, jaundice, and other visceral obstructions in the early stages; and is affirmed to have done good even in pulmonary consumption. The usual form of administration is that of decoction, which is prepared by boiling one or two ounces of the root, or a handful of the herb, in a pint of water. The root, dried and roasted, is much used in certain parts of Europe as a substitute for coffee, and is said also to be mixed fraudulently with ground coffee for sale. In preparing it for coffee, Dausse recommends that the dried root should be cut into rather large and equal pieces, which are to be roasted until they lose 140 out of 500 parts. The pieces are then easily ground in a mill, and afford a yellowish-brown powder. (*Pharm. Cent. Blatt*, Oct. 1850, p. 688.) The plant is now largely cultivated both in England and on the Continent, to supply the demand for its root, which has grown out of its use for admixture with coffee, or as a substitute. In France alone the annual consumption is said to be 16 millions of pounds. (*Pharm. Journ.*, Aug. 1860, p. 125.) An instrument by means of which it may readily be detected when used to adulterate coffee, will be found described and figured in the *Pharmaceutical Journal* (Sept. 1867, p. 141). The *garden endive* is a species of Cichorium, denominated *C. Endivia.* W.

CICUTA VIROSA. *Water Hemlock. Cowbane.* A perennial, umbelliferous European

plant, growing on the borders of pools and streams. It is very poisonous, proving fatal to most animals which feed upon it, though said to be eaten with impunity by goats and sheep. Several instances are on record of children who have died from eating the root by mistake for parsnep. It operates as an acrid narcotic, producing inflammation of the stomach, together with symptoms which indicate cerebral disturbance, such as vertigo, intoxication, and convulsions. Infusion of galls is recommended as an antidote, but should not be relied on to the exclusion of emetics. When the plant vomits, as it frequently does, fatal effects are less apt to ensue. It is said to be less poisonous dried than fresh; and it has been inferred that the active principle is volatile. But the volatile oil, obtained by distillation, was found by Simon, of Berlin, not to be poisonous. Indeed, from the experiments of M. Julius Trapp, of St. Petersburg, it appears to be identical with the volatile oil of cummin seeds (*Cuminum Cyminum*), which rank among the aromatics. (*Chem. Central Blatt*, June 9, 1858, p. 414.) On the other hand, the alcoholic extract of the dried root operated as a violent poison upon animals. (*Annal. der Pharm.*, xxxi. 258.) At present the plant is never used internally, having been superseded by *Conium maculatum*. Externally it is sometimes employed as an anodyne poultice in local pains, particularly those of a rheumatic or gouty nature.

Cicuta maculata, or *American water hemlock*, which grows in meadows and on the borders of streams throughout the United States, is closely analogous, in botanical character and in effects, to the European species. In several instances, children have been fatally poisoned by eating its root. This consists of several oblong, fleshy tubers, sometimes as long as the finger, spreading out from the base of the stem, and having a smell and taste not unlike those of parsnep. Until recently it has not been used in medicine; but we are told in Mr. Stearns' account of the medical plants of Michigan, that Dr. Norton, of Minnesota, highly recommends it as a specific in nervous and sick headache. (*Proceed. of Am. Pharm. Assoc.*, 1858, p. 253.) For a full account of the plant, see *Bigelow's Medical Botany* (i.125). The seeds have been analyzed by Mr. J. E. Young, who found in them albumen, tannic acid, gum, fixed oil, resin, volatile oil, chlorophyll, colouring matter, a peculiar acid, and an organic alkaloid supposed to be identical with *conia*. (*Am. Jour. of Pharm.*, xxvii. 294.)

In cases of poisoning by either of these species of Cicuta, vomiting should be induced as speedily as possible, and maintained till the stomach is thoroughly evacuated, after which the system must be supported. W.

CITRATE OF IRON AND MAGNESIA. *Ferri et Magnesiæ Citras.* This double salt was introduced to the notice of the profession by M. Van der Corput. It is made by dissolving *two ounces* of freshly precipitated hydrated oxide of iron in a moderately heated solution of *three ounces* of citric acid, and saturating the liquor with carbonate of magnesia. The solution, after filtration, is evaporated by means of a water-bath to a syrupy consistence, and spread on glass to dry in scales. The quantity of carbonate required is nearly an ounce. Three and a quarter ounces of sulphate of iron will furnish by decomposition the necessary hydrated oxide for three ounces of the acid. (See formula for *Ferri Oxidum Hydratum.*) This salt is in transparent, greenish-yellow scales, having a slightly ferruginous, somewhat acid taste. It is very soluble in water, but insoluble in alcohol and ether. It may be given in doses of from five to ten grains, in the form of solution, syrup, or pill. See the remarks of Prof. Procter on this preparation, contained in the *American Journal of Pharmacy* (Oct. 1850, p. 315). B.

CITRATE OF SODA. *Sodæ Citras.* This salt may be formed by saturating a solution of citric acid with bicarbonate of soda, evaporating the liquid, and setting it aside to crystallize. It is a white salt, crystallized in six-sided pyramids, and having a saline taste without any bitterness. Citrate of soda has been proposed by M. Guichon, of Lyons, as a pleasant purgative, having properties similar to those of citrate of magnesia, and, though possessing a taste more decidedly saline than the latter, having the advantages of cheapness, and of a constant solubility, which permits it to be associated with other medicinal preparations. M. Dannecy recommends it in diabetes, in daily doses of from half a drachm to a drachm. (*Bulletin Gén. de Thérap.*, Avril 15, 1866.) The dose, as a cathartic, is from ten to fourteen drachms, given in simple aqueous solution, or acidulated with citric acid and sweetened. B.

CIVET. *Zibethum.* This is an odorous substance, obtained from two animals of the genus Viverra; *V. Civetta* or civet cat of Africa, and the *V. Zibetha*, which inhabits the East Indies. It is secreted into a cavity opening between the anus and external genitals, and is collected from animals confined for the purpose. It is semi-liquid, unctuous, yellowish, becoming brown and thicker by exposure to the air, of a very strong, peculiar odour, similar to that of musk, though less agreeable and less diffusible, and of a bitterish, subacrid, disagreeable fatty taste. When heated it becomes quite fluid, and at a higher temperature takes fire, and burns with a clear flame, leaving little residue. It is insoluble in water, and only slightly soluble in ether and cold alcohol; but heated alcohol dissolves it almost entirely, depositing it again upon cooling. It contains, among other ingredients, a volatile oil, fat, and free ammonia. In medicine it was formerly employed as a stimulant and antispasmodic, like castor and musk; but is now used exclusively as a perfume. W.

CLEMATIS ERECTA. *Upright Virgin's Bower.* A perennial European plant. The leaves and flowers have an acrid, burning taste. When bruised in a mortar they irritate the eyes and throat, giving rise to a flow of tears and to coughing; and applied to the skin they produce inflammation and vesication. Hence the name of *flammula Jovis*, by which the plant was known in older pharmacy. The acrimony is greatly diminished by drying. Störck found this species of Clematis useful in secondary syphillis, cancerous and other foul ulcers, and severe headaches. He gave it internally, and at the same time applied the powdered leaves to the surface of the sore. It acted as a diuretic and diaphoretic. Two or three drachms of the leaves were infused in a pint of water, of which he administered four ounces three times a day. He also employed an extract, in the dose of a grain or two in the course of a day. At present the plant is little used; but the seeds have lately been given by M. Sauveur, in the form of infusion, in two cases of Bright's disease, which appeared to be cured, or at least greatly relieved by the remedy, acting powerfully as a diuretic. (*Ann. de Thérap.*, 1866, p. 130.)

Other species of Clematis have the same acrid properties. Among these are *C. Flammula* or *sweet-scented virgin's bower*, which, though a native of Europe, is cultivated in our gardens, *C. Vitalba* or *traveller's joy*, also a native of Europe, and several indigenous species, of which *C. Virginica* or *common virgin's bower*, *C. Viorna* or *leather flower*, and *C. crispa* have been particularly cited by authors as proper substitutes for the C. erecta used by Störck. All these are climbing plants. C. Vitalba has been used in Europe with success in the cure of itch. For this purpose the roots and stems, bruised, and boiled for a short time to diminish their acrimony, were infused in boiling oil, which, thus impregnated, was applied to the skin several times a day. Twelve or fifteen applications were usually sufficient. M. Gaube has found in this species an alkaloid, which he names *clematine*, and which forms with sulphuric acid a salt crystallizable in six-sided needles; and, besides this, an acrid volatile oil analogous to mezereon in its properties, tannic acid, mucilaginous substances, and earthy salts in small proportion. (*Journ. de Pharm.*, Août, 1869, p. 122.) W.

COAL TAR. When bituminous coal is subjected to dry distillation, besides the incondensible gases which serve for lighting, and the charcoal left behind as *coke*, which is a valuable fuel, there are formed, through the reactions between the disengaged principles of the coal, numerous other products, necessarily more or less varying in character and amount, not only according to the kind of coal used, but also with the varying circumstances of the decomposing process. Most of these newly-formed bodies, all of which are volatile, are condensed into a dark thick liquid or semi-liquid substance called coal tar. Formerly this was considered as refuse matter, and the most embarrassing problem for the manufacturer was how to get rid of it most conveniently. But science and industry have combined to wrest from this seemingly useless mass many substances of great value in the arts, and several which have entered into the catalogue of remedies. In an excellent paper by M. E. Kopp, an abridgment of which is published in the *American Journal of Pharmacy* (1861, Jan., March, and May, pp. 39, 129, and 245), a general view is given of the constituents of coal tar, to which we wish to acknowledge our indebtedness for most of the statements which follow. Our purpose is to give a condensed view of these substances, and, when found of importance in their therapeutical relations, to treat of them more fully, should they not have been already commented on under distinct heads. When coal tar is submitted to distillation and rectification, it yields the following products in variable proportion. They may be arranged in the three divisions of solids, liquids, and gases.

1. *Solids.* Carbon, naphthalin, paranaphthalin or anthraccin, paraffin, chrysene, and pyrene.

2. *Liquids.* These may be subdivided into acid, neutral, and basic substances. The *acids* are rosolic, brunolic, carbolic or phenic, acetic, and butyric. The *neutral bodies* are water, essence of tar, light oil of tar, heavy oil of tar, benzole, toluole, cumole, cymole, propyl, butyl, amyl, caproyl, hexylene, and heptylene. The *bases* are ammonia, methylamin, ethylamin, anilin, quinolin, picolin, toluidin, lutidin, cumidin, pyrrhol, and phætin.

3. *Gases.* Hydrogen, carburetted hydrogen, bicarburetted hydrogen, various other carbohydrogens, carbonic oxide, sulphuret of carbon, carbonic acid, hydrosulphuric acid, and hydrocyanic acid.

Since the appearance of M. Kopp's paper, M. Berthelot has been investigating the constituents of coal tar, and has succeeded in determining among them some which had been only conjectured to be present in it, as *styroline* and the *hydruret of naphthaline*; others of which the existence has been disputed, as *cymene* and *anthracene;* and others again previously unknown, as *fluorene* and *acénaphtène*, the last of which is of peculiar interest chemically, in consequence of its artificial production by the union of naphthaline and ethylene. (*Journ. de Pharm.*, Nov. 1867, p. 338; also Dec. p. 440.) Valuable researches have also been made in this field by Mr. C. R. Warren, which are contained in the *Memoirs of the American Academy* (N. S. ix. 135), and in the *Amer. Journ. of Sci. and Arts* (A. D. 1865, vol. xl. p. 89), to which the reader is referred, as we have not space here to do justice to the subject.

Of the above substances a considerable number have not yet been individually applied to any important practical purpose. Some are so well known to the reader as to require no further notice. The remainder we shall endeavour to consider more or less fully as their novelty and importance may seem to demand.

Before submitting the tar to distillation, it is to be freed as far as possible from the ammonia it may contain, which is mixed up with the mass in impure watery solution, chiefly probably as the carbonate. For this purpose it is heated to a point between 170° and 212° F., by which it is rendered more liquid, so that the water holding the ammonia in solution can be drawn off. This impure ammoniacal liquid is afterwards treated with sulphuric acid, by which the sulphate of ammonia is obtained, and this, by sublimation with chloride of sodium, yields muriate of ammonia; and from this source almost exclusively the market is at present supplied with the different ammoniacal compounds.

Having been thus freed from ammonia, the tar is next distilled at a relatively low temperature, which is most conveniently regulated by means of steam. The object is to obtain first the lighter liquids, of which the boiling point is comparatively low. The heat employed should not exceed 390° F.; and, when the sp. gr. of the condensed products reaches 0·850, the process is suspended. The product of this first distillation is very complex, containing, among other substances, three carbohydrogens of special interest to the physician; viz., *benzole* ($C_{12}H_6$), which has already been treated of, *amyl* ($C_{10}H_{11}$), the radical of fusel oil or amylic alcohol, also before considered, and *propyl* (C_6H_7), the radical of the alkaloid *propylamia*, of which we propose to treat in the following pages. This lighter oil is known as *light oil of tar* or *coal naphtha*. It is purified by first agitating it with 5 per cent. of concentrated sulphuric acid, allowing it to rest for a day or two in order that the acid and impurities may subside, then washing it with water, and afterwards with 2 per cent. of a solution of caustic soda of the sp. gr. 1·382, to separate adhering acid, and finally distilling with a current of steam. Thus purified, it has the sp. gr. 0·815 to 0·820, and is not unfrequently sold under the name of *benzine*, which it would be well to restrict to this product, reserving the name of *benzole* for the pure carbohydrogen. Benzine is used for various purposes in the arts, generally connected with its great solvent power.

When the distillation of the tar is suspended, the steam is withdrawn, and, the heat being increased to between 390° and 410° F., the distillation recommences; and the mixed oils that now come over and condense have a sp. gr. from 0·880 to 0·885, instead of 0·850, the sp. gr. of the lighter oil. This heavier product is distinguished by the name of the *heavy oil of tar*. It contains the acids and organic bases already enumerated, from which it is freed by treatment with sulphuric acid and one of the fixed alkalies and redistillation, in the same manner as above described for the light oil, using 10 per cent. of sulphuric acid instead of 5, and 6 per cent. of solution of soda instead of 2. The heavy oil thus purified is used as lamp oil, and is very largely consumed. Before distillation this oil has a disagreeable sulphurous odour, owing to the decomposition of the sulphuric acid used in purifying it, from which it is freed by shaking it with solution of sulphate of iron before distillation, or, after distillation, with addition of caustic soda to the sulphate. A blackish deposit of sulphuret of iron takes place, and the oil loses its odour. (*Kopp.*)

The solid or semi-solid mass, which forms out of the last products of the distillation upon cooling, is also complex; but consists largely of the two concrete bodies, naphthalin and paraffin, the proportion of each of which to the other varies according to the kind of coal used, and to the degree of heat employed. According to Mr. Joseph Taylor, the product of naphthalin is very great when the coal has been decomposed at a high temperature. He states that it is easily obtained from the latter portions of the light oil, which, if collected separately and set aside, become semi-solid on cooling. This concrete mass is pressed to separate the liquid portion, and may be purified by crystallization from naphtha or sublimation. *Paraffin*, according to the same authority, exists in small quantity in coal tar, being destroyed by the high temperature necessary in decomposing the coal in the manufacture of gas. (*Pharm. Journ.*, Jan. 1861, p. 364.) M. Kopp, on the contrary, states that the tar from Boghead coals is rich in paraffin. (*Am. Journ. of Pharm.*, Jan. 1861, p. 41.) When the last products of distillation cool, this separates as a buttery mass, while naphthalin, under similar circumstances, assumes a crystalline character. The paraffin and the heavy oil which drains from it, and which is called *paraffin oil*, are purified in the same manner as the lighter and heavier oils above referred to by sulphuric acid, which, however, is sometimes aided by oxidizing agents, such as bichromate of potassa, peroxide of manganese, or permanganate of potassa, and subsequent washing with solution of caustic soda. After this the paraffin is either redistilled, or purified by a second treatment with sulphuric acid and washing. It is now mixed with 1 per cent. of stearic acid, which, on the addition of the caustic soda, forms a soap which, when the paraffin is melted, envelops the impurities, and separates in flocculi, leaving the paraffin pure. *Paraffin* having been already described under the head of *Creasotum*, in *Part* I. (*page* 341), requires no further consideration here; and *naphthalin* will be considered in its proper alphabetical position in the present part of this work. It may be worth mentioning that death has occurred in a woman in consequence of swallowing paraffin oil largely. (*Pharm. Journ.*, July, 1865, p. 38.)

The acid and alkaline washings resulting from the purifying processes to which the oils have been subjected contain all the acids and alkaloids already mentioned as among the products of the distillation of coal tar. It has become important to obtain these separate, as some of them have recently acquired great value in the arts as the source of colouring substances used in dyeing, and others are employed as medicines. M. Kopp

proposes the following method of obtaining them. Collect separately the acid and the alkaline liquors, determine how much of the latter would suffice to neutralize a given portion of the former, then mix the alkaline solution with twice the quantity of acid sufficient to saturate it. If the mixture be quickly made a heat will be generated near to the boiling point; and a concentrated solution of bisulphate of soda will be formed, holding in solution the bisulphates of the organic alkaloids, while the carbolic acid and creasote will separate in the form of a brown oil. If this be removed and distilled, a light neutral oil will first pass, and then the creasote and carbolic acid nearly pure; and it is probably this mixture or some one like it that is now improperly sold in the market under the name of creasote. The acid solution, being now allowed to cool, deposits bisulphate of soda in crystals. The portion of acid solution, not used to saturate the alkaline, may now be added, the mixture heated to 150° or 180° F., chalk or lime added short of complete saturation, and the liquor concentrated. After the deposit of sulphate of lime has been separated, the concentrated solution of the acid sulphates is to be mixed with an excess of quicklime, and distilled from an iron retort. Sulphate of lime is left behind, and the liberated alkaloids pass over and condense with water. If the water be sufficient to hold them in solution, muriatic acid is to be added to saturation, and the liquor evaporated, first over the naked fire, but towards the close upon a water-bath, nearly to dryness. The muriates thus formed are mixed with an excess of lime and distilled, and an oily liquid is thus obtained, consisting chiefly of the alkaloids, anilin (anilia), quinolin (quinolia), and toluidin (toluidia), sufficiently pure to be used in preparing the various colouring substances, which constitute all their value in the arts. Of the different products resulting from the above process, all that are used in medicine, namely *creasote*, *carbolic acid*, and *anilin*, have been treated of under distinct heads in this work, to which the reader is referred. (See *Creasotum* in *Part* I., and *Anilin* and *Carbolic Acid*, in their proper alphabetical positions in *Part* III.)

This is not the place to treat of the methods in which the several beautiful and magnificent colours are prepared from anilin and the other coal-tar alkaloids; as the subject belongs exclusively to the arts. It will be sufficient to refer to the fine *anilin violet*, produced by reaction with bichromate of potassa; the magnificent purple called *fuchsin* or *magenta*, resulting from the reaction between anilin and chloride of tin; and the splendid *anilin red* obtained by treating the same alkaloid with bichloride of mercury or perchloride of tin. Yellows, greens, and various other tints are prepared either with anilin or the other coal-tar alkaloids, which appear to share its wonderful colouring powers.

The residue of coal tar left after its distillation, commonly called *pitch*, has also been applied to various useful purposes; being mixed with coal dust or small fragments of coal, otherwise useless, to fit them for fuel; or used as a paint to wood in order to preserve it; or employed in the preparation of what are called asphaltum pavements and for covering roofs. (*Taylor.*)

Coal tar itself has been ascertained to answer admirably well, in certain instances, the purposes of a disinfectant. MM. Corne and Demeaux prepared a mixture of coal tar and plaster of Paris, in the proportion of from one to three parts of the former to one hundred of the latter, which, having been submitted for trial to a committee of the Academy of Sciences of Paris, was reported on favourably by the committee, of which M. Velpeau was at the head. The mixture should be made of the best modelling plaster, and should have a gray colour after the ingredients have been well rubbed together. It is in the form of powder, and may be applied on lint, or mixed with cataplasms, or sprinkled thickly on ulcerated surfaces. It is applicable to fetid, sloughing, or gangrenous ulcers, to offensive suppurating surfaces, sanious wounds, &c., and may be used also to correct disagreeable odours, in autopsies, about the beds of dirty patients, and wherever there are fetid discharges. (*Journ. de Pharm.*, Oct. 1859, p. 296.) It may sometimes be advisable to employ coal tar for the same purpose in the liquid form, made by emulsionizing it; but this cannot be effected, as in the case of wood tar, by means of the carbonated alkalies. It is asserted by M. Jeannel that the only known means of obtaining this result, up to the time at which he wrote (A. D. 1866), was by the use of a tincture of the soap bark (bark of *Quillaya saponaria*), as proposed by M. Lebœuf. This tincture is prepared for the purpose by digesting, for some days, one part of the bark finely bruised with four parts of alcohol of 90°. The emulsion is made by digesting ten parts of coal tar with twelve of the tincture. It makes a stable mixture with water. (*Journ. de Pharm.*, 4e sér., iv. 285.)

W.

COBALT BLUE. This beautiful pigment is a compound of oxide of cobalt and alumina, obtained by precipitating the mixed solutions of a salt of alumina and of cobalt by means of an alkali, and washing, drying, and strongly calcining the precipitate. (*Berzelius.*) The cobalt blue of Thenard is made by heating together the hydrated subphosphate of cobalt and hydrate of alumina. It is used in painting. An oxide of cobalt, prepared by precipitating the chloride with potassa, has been employed in rheumatism. It is emetic in the dose of 10 or 20 grains. The salts of the metal are irritant poisons. W.

COBWEB. *Spiders' Web. Tela Aranceæ.* The genus *Aranea* of Linn. has been divided by subsequent naturalists into several genera, of which the *Tegeneria* of Walkenaer is the one that includes the medicinal species of spider. The *T. domestica* of Europe, and *T. medicin-*

alis of this country (Henz, *Journ. Acad. of Nat. Sci.*, ii. 53), are the particular species which have attracted most attention. They inhabit cellars, barns, and other dark places, and are of a brown or blackish colour. It is affirmed that the web of the field spider is inefficacious, while that collected in the cellars of houses, etc. has extraordinary medical virtues. Several authors speak in very decided terms of its powers as a febrifuge and antispasmodic. According to Dr. Robert Jackson, it is superior even to bark and arsenic in the cure of intermittents, and is, moreover, highly useful in various spasmodic and nervous diseases, controlling and tranquillizing irregular nervous action, exhilarating the spirits, and disposing to sleep, without producing any of the narcotic effects of opium on the brain. Among the complaints in which it has been found useful, besides intermittent fever, are periodical headache, hectic fever, asthma, hysteria, and nervous irritations attended with morbid vigilance and irregular muscular action. Dr. J. Donaldson, of Madras, India, has recently found it remarkably successful in fever, considering it sometimes preferable to quinia. (*Lancet*, Feb. 16, 1867, p. 212.) It will be observed that these are, for the most part, affections over which the imagination has much control. The dose of spiders' web is five or six grains, to be given in the form of pill, and repeated every three or four hours. Dr. Jackson states that its influence is not in proportion to the quantity administered, and that he obtained the same effects from ten as from twenty grains. This might well be, if the supposition be allowed that its chief operation is through the imagination. Spiders' web has also been used, with asserted advantage, as a styptic in wounds, and a healing application to superficial ulcers. In the *Dental Cosmos* (Nov. 1866), Mr. A. Robertson, of Wheeling, Va., records a case, in which hemorrhage from the socket of an extracted tooth, after resisting the most energetic styptics, yielded immediately to spiders' web stuffed into the socket. (*Am. Journ. of Pharm.*, Jan. 1867, p. 67.) Spiders themselves were formerly employed in the treatment of intermittent fever, and this application of the web is not of recent origin. W.

COCCULUS. *Cocculus Indicus.* Having been dismissed from the British Pharmacopœia, this substance is inserted here in accordance with our usual custom. The plant which produces cocculus Indicus was embraced by Linnæus, with several others, under the title of *Menispermum Cocculus*. These were referred by De Candolle to a new genus, denominated *Cocculus*. From this the particular species under consideration has been separated by Wight and Arnott, and erected into a distinct genus with the name of *Anamirta*.

The genus Anamirta belongs to *Dicœcia Dodecandria* of the sexual system, and to the natural order *Menispermaceæ*. The following is the *generic character*. Flowers dicœcious. *Calyx* of six sepals in a double series, with two close-pressed bracteoles. *Corolla* none. MALE. *Stamens* united into a central column dilated at the apex. *Anthers* numerous, covering the whole globose apex of the column. FEMALE. *Flowers* unknown. *Drupes* one to three, one-celled, one-seeded. *Seed* globose, deeply excavated at the hilum. *Albumen* fleshy. *Cotyledons* very thin, diverging. (*Wight and Arnott.*)

Anamirta Cocculus. Wight and Arnott, *Flor. Penins. Ind. Orient.* i. 446; Lindley, *Flor. Med.* 371.—*Menispermum Cocculus.* Linn.—*Cocculus suberosus.* De Cand. *Prodrom.* i. 97. This is the only species. It is a climbing shrub, with a suberose or corky bark; thick, coriaceous, smooth, shining, roundish or cordate leaves, sometimes truncate at the base; and the flowers in lateral compound racemes. It is a native of the Malabar Coast, and of Eastern Insular and Continental India. The fruit is the officinal portion.

This plant was proved to be the source of cocculus Indicus by Roxburgh, who raised it from genuine seeds which he had received from Malabar. It is believed that other allied plants, bearing similar fruit, contribute to furnish the drug; and the *Cocculus Plukenetii* of Malabar, and *C. lacunosus* of Celebes and the Moluccas, are particularly designated by authors. It was known to the Arabian physicians, and for a long time was imported into Europe from the Levant, from which circumstance it was called *cocculus Levanticus*. It is now brought exclusively from the East Indies.

Properties, &c. Cocculus Indicus, as found in the shops, is roundish, somewhat kidney-shaped, about as large as a pea; having a thin, dry, blackish, wrinkled exterior coat, within which is a ligneous bivalvular shell, enclosing a whitish, oily, very bitter kernel. It is without smell, but has an intensely and permanently bitter taste. It bears some resemblance to the bay berry, but is not quite so large, and may be distinguished by the fact, that in the cocculus Indicus the kernel never wholly fills the shell. When the fruit is kept long, the shell is sometimes almost empty. The Edinburgh College directed that "the kernels should fill at least two-thirds of the fruit." M. Boullay discovered in the seeds a peculiar bitter principle which he denominated *picrotoxin*. This is white, crystallizable in quadrangular prisms, soluble in 25 parts of boiling and 150 of cold water (*Glover*), and very soluble in alcohol and ether, but insoluble in the oils. Its composition is $C_{12}H_7O_5$ (*Pelletier and Couerbe*), or $C_{20}H_{12}O_8$, according to Gmelin, who considers it as isomeric with cantharidin. (*Handbook*, xiv. 475.) It is poisonous, and, given to strong dogs in the quantity of from five to ten grains, produces death, preceded by convulsions, which, according to Dr. R. M. Glover, are very similar in character to those produced by Flourens by section of the corpora quadrigemina and cerebellum; being attended with backward and rotary movements and tetanic spasms. It also greatly increases the animal heat. (*Ed. Monthly Journ. of Med. Sci.*, N. S., iii. 303.) To procure it, the watery

extract of the seeds is triturated with pure magnesia, and then treated with hot alcohol, which dissolves the picrotoxin, and yields it upon evaporation. In this state, however, it is impure. To obtain it colourless it must be again dissolved in alcohol, and treated with animal charcoal. After filtration and due evaporation, it is deposited in the crystalline form. Besides picrotoxin, cocculus Indicus contains a large proportion of fixed oil, and other substances of less interest. The active principle above described is said to reside exclusively in the kernel. In the shell MM. Pelletier and Couerbe discovered two distinct principles; one alkaline and named *menispermin* (menispermia), the other identical with it in composition, but distinguishable by its want of alkalinity, its volatility, and its solubility and crystalline form, and denominated *paramenispermin.* They found also in the shell a new acid, which they called *hypopicrotoxic.* The picrotoxin of M Boullay they believed to possess acid properties, and proposed for it the name of *picrotoxic acid.* (*Journ. de Pharm.*, xx. 122.) In Europe, picrotoxin is said to be added to malt liquors, in order to give them bitterness and intoxicating properties; although the practice is forbidden by the law, in England, under heavy penalties.

Gunckel proposes the following mode of detecting and separating picrotoxin from liquids containing it, founded on the facts, that it is soluble in dilute acids though not combining with them, and that ether extracts it from its acidulous solutions, but not from those in water or alcohol, even with the presence of potassa. The substance suspected to contain it, having been brought to the consistence of paste, is to be digested with alcohol and a little tartaric acid, the liquid separated, the alcohol evaporated, the residue diluted with a little water and then treated with ether, and, finally, the etheral solution submitted to evaporation in a watch-glass. Picrotoxin, if present, is deposited, recognisable by its feathery crystallization, its bitter taste, and the property of reducing the tartrate of copper and potassa. If strychnia, which perhaps resembles it most closely in its effects, should have been present, it would be left behind in the acidulated solution. (*Journ. de Pharm.*, Juillet, 1858, p. 78; from *Archiv. der Pharm.*, xciv. 14.) In the instance of adulterated malt liquor, in consequence of the resin of hops it contains, it might be expedient first to evaporate the liquor to dryness, and prepare a watery extract of the residue, and then to proceed as stated.

Mr. J. W. Langley proposes, as a means of detection, the oxidation of picrotoxin. When to a little of this substance, mixed with nitrate of potassa in a watch-glass, a drop of sulphuric acid is added, no observable reaction takes place; but, if a very strong solution of caustic potassa or soda be now added, a bright reddish-yellow colour is produced, which is highly characteristic. A very minute quantity may thus be detected. Mr. Langley, however, thinks it extremely probable that this phenomenon is owing to a minute quantity of some nitrogenous principle strongly attached to the picrotoxin; for, if this principle be purified by combining it in solution with potassa, and then precipitating it with an acid, it does not answer the test. (*Am. Journ. of Sci. and Arts*, July, 1862, p. 109.)

Medical Properties, &c. Cocculus Indicus acts in the manner of the acrid narcotic poisons, but is never given internally. In India it is used to stupefy fishes in order that they may be caught; and it has been applied to the same purpose in Europe and this country. It is asserted that the fish thus taken are not poisonous. The powdered fruit, mixed with oil, is employed in the East Indies as a local application in obstinate cutaneous affections. An ointment made with the powder has been used in tinea capitis, and to destroy vermin in the hair. Picrotoxin has been successfully substituted by Dr. Jeager for the drug itself. Rubbed up with lard in the proportion of ten grains to the ounce, it usually effected cures of tinea capitis in less than a month. A case is recorded by W. B. Thompson, of New York, in which death in a child six years old, preceded by tetanic spasms, and extremely contracted pupil, resulted from the application of a strong tincture of the fruit to the scalp. (*Med. Exam.*, N. S., viii. 227.) It should be used with great caution when the surface is abraded.

Fluid Extract of Cocculus Indicus is a convenient form for external use. Prof. Procter prepares it by moistening a moderately coarse powder, obtained from 16 troyounces of the fruit, with 6 ounces of a menstruum composed of two parts of alcohol and one of water; packing the mixture, after two hours, in a conical percolator; pouring upon it a similar menstruum till twelve fluidounces have passed; digesting the coatings, from which the powder was sifted, in two pints of diluted alcohol; pouring the whole, when cool, into the percolator; after the liquid has disappeared, pouring on diluted alcohol until two pints of filtered liquor are obtained; evaporating this to four fluidounces; mixing the residue with the reserved tincture; and, after 24 hours, filtering through paper. (*Am. Journ. of Pharm.*, March, 1863, p. 112.) W.

COCHLEARIA OFFICINALIS. *Common Scurvy-grass.* This is an annual or biennial plant, sending up early in the spring a tuft of radical leaves, which are heart-shaped, roundish, of a deep shining-green colour, and supported on long footstalks. The leaves of the stem are alternate, oblong, somewhat sinuate, the lower petiolate, the upper sessile. The stem is erect, branched, angular, six or eight inches high, and bears, at the extremity of the branches, numerous white cruciform pedunculed flowers in thick clusters. The fruit is a roundish two-celled pod, containing numerous seeds. The whole plant is smooth and

succulent. It is a native of the northern countries of Europe, where, as well as in the United States, it is occasionally cultivated in gardens. The whole herb is officinal. It has, when fresh, a pungent, unpleasant odour if bruised, and a warm, acrid, bitter taste. These properties are lost by drying. They are imparted to water and alcohol by maceration, are retained by the expressed juice, and probably depend on a peculiar volatile oil, which is separable in very small quantity by distillation with water. Dr. Geiseler has shown that, when the dried herb is mixed with water and a little myrosin (see *Sinapis*), the taste and smell of the fresh plant are developed; proving that, as in black mustard, the volatile oil is produced by reaction between a fixed principle in the plant and water, under the influence of myrosin acting as a ferment. (*Chem. Cent. Blatt*, Feb. 20, 1856, p. 124.) The oil was at one time supposed to be identical with the oil of mustard, but M. Geiseler has shown it to have a different composition; its formula being C_6H_5O,S, which is oil of garlic plus one eq. of oxygen. (See *Am. Journ. of Pharm.*, Sept. 1859, p. 416.) The boiling point also differs, being, according to Dr. A. W. Hoffmann, about 160° C.; while that of mustard is 147° C. (*Chem. News*, June 1, 1869, p. 286.)

Common scurvy-grass is gently stimulant, aperient, and diuretic. It is highly celebrated as a remedy in sea-scurvy, and has been recommended in chronic obstructions of the viscera, and certain forms of chronic rheumatism. The fresh plant may be eaten as a salad, or used in the form of infusion in water or wine, or of the expressed juice. Alcohol and water are impregnated with its virtues by distillation; and the distilled spirit has been found useful in paralysis, in the dose of thirty drops several times a day. The expressed juice may be used as a local application in scorbutic affections of the gums. W.

COCO-NUT OIL. *Cocoa-nut Oil. Cocoa-nut Butter.* This must not be confounded with the fixed oil of the chocolate nut, which is often called *cocoa-butter*, and which has been described in *Part* I. (*page* 620). The substance here considered is the fixed oil of the coco-nut, which is the fruit of a species of palm, denominated botanically *Cocos nucifera*, and universally known by the name of *coco-nut tree*, or, as it is frequently spelled, *cocoa-nut tree*. The oil is obtained either by expression or decoction. It is of a fine white colour, of the consistence of lard at ordinary temperatures, becoming solid, like suet, between 40° and 50°, and liquid at about 80°, of a bland taste, and a peculiar, not disagreeable odour. It is readily dissolved by alcohol. According to Brandes, it consists mainly of a peculiar fatty principle, called *cocin*, which yields *cocinic acid* by saponification. (*Journ. de Pharm.*, xxiv. 652.) It has since been found to contain several solid and volatile acids, as caproic, caprylic, capric, and pichuric acids. (*Ibid.*, 3e sér., xv. 69.)

This oil has been used for various purposes in medicine and pharmacy. Dr. Theophilus Thomson has found it to possess virtues similar to those of cod-liver oil, and has used it with advantage in consumption. In some instances it appeared to arrest the progress of phthisis as decisively as that oil, over which it has the advantages of being cheaper, more palatable, and less apt to produce nausea. (*Clin. Lect. on Pulmonary Consumption*, Am. ed., p. 128.) Dr. J. H. Warren, of Boston, gives similar testimony in its favour. (*Bost. Med. and Surg. Journ.*, lii. 377.) In Germany it has been used in pharmacy, to a considerable extent, as a substitute for lard, to which, according to Pettenkofer, it is preferable on account of its less tendency to rancidity, its more ready absorption when rubbed on the surface of the body, and its less liability to produce chemical changes in the substances with which it is associated. Thus, the ointment of iodide of potassium, when made with lard, becomes yellow in a few days; while, if made with coco-nut oil, it remains unchanged for two months or more. Vegetable substances also keep better in ointment prepared with this oil than with lard. Besides, it takes up one-third more water, which is a useful quality, when it is desirable to apply saline solutions externally. To prepare it for use, nothing more is ordinarily necessary than to melt it at a moderate heat, and strain it through linen. If coloured, it may be digested with powdered animal charcoal, and subsequently filtered through paper. (*Am. Journ. of Pharm.*, xxix. 331; from *Buchner's Repertorium*, 1856, 485–8.) Coco-nut oil has been used in the manufacture of soap; but we are told that the soap acquires a very offensive odour when long kept. A preparation has been shown to us, said to be the liquid part of coco-nut oil, prepared in London, and, under the name of *coco-olein*, used, instead of the oil itself, as a substitute for cod-liver oil. The dose of this, as well as of the oil, is half a fluidounce three times a day. If the oil is used, it may be readily brought to the liquid state by a gentle heat. W.

CŒLOCLINE POLYCARPA (Alphonse De Candolle). *Unona polycarpa* (De Cand). *Berberin Tree. Yellow-dye Tree of Soudan.* This is a small tree, growing in Soudan, Sierra Leone, and other parts of Western Africa, the bark of which has recently come into notice, through the researches of Dr. Wm. F. Daniell, who has described both the tree and its bark in a paper, published in the *Pharmaceutical Journal* for Feb. 1857 (p. 398). When wounded the tree exudes a juice which produces a yellow stain upon linen, that cannot be washed out. The epidermis of the bark is greenish-gray, interrupted by occasional blackish patches; the inner layers are of a golden yellow, and very fibrous, so that they can be separated in riband-like bands. The bark is moderately but disagreeably bitter, and stains the saliva yellow. Water extracts its colour and bitterness. Dr. Stenhouse has ascertained that it contains *berberina*, found also in columbo, and in Berberis vulgaris. The bark is

much used in Africa for dyeing yellow. In Sierra Leone it is employed topically, with asserted advantage, in the treatment of obstinate ulcers, being applied both in the state of powder and in decoction. W.

COLLINSONIA CANADENSIS. *Horse-weed. Horse-balm. Richweed. Heal-all. Stone-root. Knot-root.* An indigenous plant, with a perennial, knotty root, and an herbaceous simple stem, about two feet high, furnished with two or three pairs of broad cordate-ovate, smooth leaves, and terminating in a panicle of yellow flowers in branched racemes. The flowers are diandrous and monogynous, with a labiate calyx and corolla, the latter of which has the lower lip fringed. The plant grows in woods from Canada to the Carolinas, and flowers from July to September. The whole plant has a strong disagreeable odour, and a warm pungent taste. It is considered tonic, astringent, diaphoretic, and diuretic; and the root, in substance, is said to irritate the stomach, and produce vomiting, even in small doses. The plant is used in numerous complaints in domestic practice. It is preferred in the fresh state, as the active principle is volatile. A decoction of the fresh root is said to have been used with advantage in catarrh of the bladder, leucorrhœa, gravel, dropsy, and other complaints; and the leaves are applied by the country people, in the form of cataplasm or fomentation, to wounds, bruises, and sores, and in cases of internal abdominal pains. W.

COLUTEA ARBORESCENS. *Bladder Senna.* A shrub growing spontaneously in the southern and eastern parts of Europe, and cultivated in gardens as an ornamental plant. Its leaves are pinnate, consisting of from three to five pairs of leaflets, with an odd one at the end. The leaflets are obovate, slightly emarginate, smooth, and of a deep-green colour on the upper surface, grayish-green and somewhat pubescent beneath. The flowers are yellow, and the fruit vesicular, whence the plant derived its vulgar name. The leaflets are purgative, and, in some parts of Europe, are used as a substitute for senna, which is said to be sometimes adulterated with them. Bladder senna is comparatively very feeble. It is administered in infusion or decoction, of which the dose is about half a pint, containing the virtues of from one to three ounces of the leaves. W.

COLZA OIL. This is an oil expressed from the seeds of the *Brassica campestris*, or field cabbage, a cruciferous plant which grows wild through the greater part of Europe, and is largely cultivated in France and Germany, where the fields, at its period of flowering, are beautiful with its bright-yellow blossoms. It is cultivated for the sake of the oil, obtained by expression from its seeds, which is largely used in the arts, though, in consequence of its unpleasant taste, unfitted for the table. W.

COMPTONIA ASPLENIFOLIA. *Sweet Fern.* A shrubby, indigenous plant, named from the resemblance of its leaves to the *spleenwort fern*, and belonging to the Linnæan class and order *Monœcia Triandria*. It grows in thin sandy or stony woods, from New England to Virginia. All parts of it possess a resinous spicy odour, which is increased when the plant is rubbed. It is said to be tonic and astringent, and to be occasionally used in domestic practice as a remedy in diarrhœa, and various other complaints. It is employed in the form of decoction. W.

CONIOSELENIUM CANADENSE. *Hemlock Parsley.* (*Gray's Manual*, p. 154.) This plant grows in swamps in the northern parts of the United States and in Canada. It has recently come into notice as one of a combination of native plants, recommended as having peculiar efficacy in dysentery, by Mr. Wm. Kerr. After experimenting with a great variety of medicines, officinal and non-officinal, in this complaint, Mr. Kerr believed that he had hit on a combination having special powers in its cure; and other practitioners in Canada join with him in recommending it from their own experience. The constituents of this compound are four officinal medicines, opium, stramonium, dulcamara, and digitalis, and three non-officinal, *Sium lineare*, *Cicuta maculata*, and *Coniosclenium Canadense*. (*Edin. Med. Journ.*, June, 1865, p. 1106.) The parts of the plant used, and the mode of preparing them, are not mentioned in the paper; and the preparation would scarcely have been noticed here, except that attention is called to a new medicine, Coniosclenium Canadense, which may possibly possess useful remedial properties, and is worthy of being further investigated. W.

CONTRAYERVA. *Contrayerva.* This is the root of Dorstenia Contrayerva, and formerly held a place in the secondary catalogue of the U. S. Pharmacopœia, but was dismissed at the late revision, and has now ceased to be officinal. The plant belongs to Tetrandria Monogynia of the Linnæan system, and to the natural order Urticaceæ. The following is its generic character:—"*Receptacle* common, one-leafed, fleshy, in which solitary *seeds* are nestled." (*Willd.*) This plant has a perennial, fusiform, branching, rough, compact root or rhizoma, which sends up several leaves of an irregular shape, about four inches in length, lobed, serrated, pointed, and placed upon long radical footstalks, which are winged towards the leaves. The scapes or flower-stems are also radical, rise several inches in height, and support irregular quadrangular receptacles, which contain male and female flowers, the former having two stamens, the latter a single style. The capsule, when ripe, possesses an elastic power, by which the seeds are thrown out with considerable force. The plant grows in Mexico, the West Indies, and Peru. The root (rhizoma) is the officinal portion. According to Pereira, however, the contrayerva of the shops is the product of

D. Brasiliensis, and is brought from Brazil. The term contrayerba, in the language of the Spanish Americans, signifies *counterpoison* or *antidote*, and was applied to this root under the impression that it had the property of counteracting all kinds of poison. The probability is that the root sold as *contrayerva* is derived from several species of Dorstenia, among which, besides *D. Contrayerva*, two others are mentioned by Dr. Houston, *D. Houstonia* and *D. Drakena*, the former growing near Campeachy, the latter near Vera Cruz. It is referred by Dr. Martius also to *D. Brasiliensis*, growing in Jamaica, Trinidad, and Brazil. D. Contrayerva was the only one recognised in the Pharmacopœia.

Properties. The root, as found in our shops, is oblong, an inch or two in length, of varying thickness, very hard, rough, and solid, of a reddish-brown colour externally, and pale within; and has numerous, long, slender, yellowish fibres attached to its inferior part. The odour is aromatic; the taste, warm, slightly bitterish, and pungent. The fibres have less taste and smell than the tuberous portion. The sensible properties are extracted by alcohol and boiling water. The decoction is highly mucilaginous. The tincture reddens infusion of litmus, and lets fall a precipitate on the addition of water. The root, so far as we know, has not yet been analyzed, but contains starch and a volatile oil. Contrayerva is a stimulant tonic and diaphoretic, and has been given in low states of fever, malignant eruptive diseases, some forms of dysentery and diarrhœa, and other diseases requiring gentle stimulation. It is very seldom used in this country. The dose of the powdered root is about half a drachm. W.

CONVALLARIA MAJALIS. *Lily of the Valley.* This charming little garden flower is a native of Europe, and is found growing wild in the United States, upon the highest mountains of Virginia and Carolina. The *flowers* have a strong, delightful odour, which is in a great measure lost by drying. Their taste is nauseous, bitter, and acrid. G. F. Walz has found in the herb and root two peculiar principles, one crystalline and acrid, which he calls *convallarin*, the other amorphous and bitter, and named *convallamarin*. For the mode of preparing them the reader is referred to the *Am. Journ. of Pharm.* (Nov. 1859, p. 577). Convallarin is in colourless rectangular prisms, scarcely soluble in water, but sufficiently so to render the solution acrid, and to cause it when shaken to foam like soap and water. It is easily dissolved by alcohol. Its composition is represented by the formula $C_{34}H_{31}O_{11}$. It is a glucoside. Convallamarin is a white powder, very bitter and afterwards sweetish, soluble in water and alcohol, but not in ether. This also is a glucoside. Its composition is $C_{46}H_{44}O_{24}$. Taken internally the flowers are said to be emetic and cathartic, and their extract purges actively in the dose of half a drachm. They were formerly used in epilepsy and against worms. At present they are employed only as a sternutatory, for which purpose they are dried and reduced to a coarse powder. The *root*, which is also bitter, has similar purgative properties, and, reduced to powder, is said to be sternutatory. From the analysis of Mr. Walz, it is probable that the virtues reside in the whole plant, and that it combines emetic and cathartic with tonic properties. The effects on the system of the two principles above mentioned have been investigated by Dr. H. Marme, of Germany, with the following results. *Convallarin*, in doses of 3 or 4 grains, acts as a purgative, without observable inconvenience to the animals acted on; *convallamarin*, even in small doses, produces active vomiting, whether given by the mouth or injected into the subcutaneous tissue, or directly into the veins. The latter principle acts specially on the heart, at first diminishing the number of its pulsations, and afterwards rendering them more frequent and irregular, and causing death in a few minutes after the introduction of the poison. The heart appears to be paralyzed, and cannot be excited after death. The principle acts on the heart through the vagi nerves, and resembles digitalis in its mode of operation. From 6 to 8 milligrammes caused death, when injected into the cervical vein in rabbits, 15 to 20 in dogs. (*N. Y. Med. Journ.*, Nov. 1867, p. 166; *Schmidt's Jahrbuch*, 1867, v. 166.) W.

CONVALLARIA POLYGONATUM. Linn. *Polygonatum uniflorum.* Desfontaines. —*Solomon's Seal.* A perennial, herbaceous, European plant, the root of which is horizontal, jointed, white, and marked, at short intervals, with small circular impressions, which bear a remote resemblance to those made by a seal, and have served to give a name to the plant. The root is inodorous, and of a sweetish mucilaginous taste, followed by a slight degree of bitterness and acrimony. It is said to be emetic. In former times it was used externally in bruises, especially those about the eyes, in tumours, wounds, and cutaneous eruptions, and was highly esteemed as a cosmetic. At present it is not employed, though recommended by Hermann as a good remedy in gout and rheumatism. The berries and flowers are said to be acrid and poisonous. *C. multiflora* (*Polygonatum multiflorum*, Desf.), which grows both in this country and Europe, is analogous to the preceding in properties. Dr. John H. Rauch found two fluidounces of a decoction, made by boiling two ounces of the root in a pint of milk, to produce nausea, a cathartic effect, and either diaphoresis or diuresis. He used it advantageously as an internal remedy in piles, and externally in the form of decoction, in the affection of the skin resulting from the poisonous exhalations of certain plants. (*Inaugural Essay*, March, 1849.) W.

CONVOLVULUS PANDURATUS. *Wild Potato.* Under this name, the root of *Convolvulus panduratus* was formerly recognised in the secondary list of the U. S. Pharma-

copœia, from which, however, it was dismissed at the recent revision. The wild potato plant (for a figure of which see *Barton's Med. Bot.* i. 249) has a perennial root, and a round, purplish, procumbent or climbing stem, which twines around neighbouring objects, and grows sometimes twelve feet in length. The leaves, which stand alternately on long petioles, are broad, heart-shaped at the base, entire or lobed on the sides like a guitar or violin, somewhat acuminate, deep-green on the upper surface, and paler beneath. The flowers are in fascicles, upon long axillary peduncles. The calyx is smooth and awnless; the corolla, tubular, campanulate, very large, white at the border, but purplish-red at the base. The plant is indigenous, growing throughout the United States in sandy fields and along fences, and flowering from June to August. A variety with double flowers is cultivated in the gardens for the sake of ornament. The root, which was the officinal part, is very large, two or three feet in length, about three inches thick, branched at the bottom, externally of a brownish-yellow colour, and full of longitudinal fissures, internally whitish and milky, and of a somewhat acrid taste. The wild potato is feebly cathartic, and has been proposed as a substitute for jalap, but is scarcely used. It is thought also to be diuretic, and has been employed, with supposed advantage, in strangury and calculous complaints. Dr. G. M. Maclean considers it one of the best diuretics he has used, when given in infusion. (*N. Y. Journ. of Med.*, x. 375.) Forty grains of the dried root are said to purge gently. W.

COPAL. A resinous substance, brought from the East Indies, South America, and the eastern and western coasts of Africa, but most abundantly from the first mentioned source. It is the concrete juice of different trees, and is furnished by exudation. The East India copal has been ascribed to the *Vateria Indica* of Linn., the *Elæocarpus copaliferus* of Retzius; and the Brazilian, by Martius and Hayne, probably with justice, to different species of *Hymenæa*. There is some reason to believe that the East India copal is also the product of a Hymenæa; at least a specimen of this resin was collected by M. Perottet from the *Hymenæa verrucosa*, which he found growing in the Isle of Bourbon. This tree is a native of Madagascar, and probably of the neighbouring parts of Africa; and M. Perottet was informed that the copal of India is taken thither by the Arabs of Muscat, who obtain it from the east coast of Africa. (*Journ. de Pharm.*, 3e sér., i. 406.) It is stated by Mr. James Vaughan, who was stationed as army surgeon at Aden in Arabia, that copal is taken to that port from the African coast opposite the island of Zanzibar, where it is said to be dug up from the earth. (*Pharm. Journ.*, xii. 385.) Col. Playfair, British Consul at Zanzibar, has sent to the Kew Museum specimens of the bark of a tree, with the resin *in situ*, and specimens of the collected resin, and of the fruit of the tree, which leave little doubt that the Zanzibar copal is obtained from the *Hymenæa Mozambicensis*. On the same authority it is stated that the value of the copal exported from Zanzibar in the year 1863–4, amounted to 163,353 dollars, of which 5000 dollars' worth was sent to the United States. (*Am. Journ. of Pharm.*, May, 1866, p. 255; from *Lond. Pharm. Journ.*) In a later communication from Dr. John Kirk, dated Zanzibar, March 20, 1865, it is stated that the smooth copal, exported from that region, is obtained from the *Trachylobium Mozambicense*, Kl., a small tree or bush, distinguished by its rounded head of glossy leaves, with groups of white flowers at the ends of the branches. The trunk and limbs are covered with a clear resinous exudation, portions of which, after solidifying, drop to the ground and are collected, while other portions are broken from the tree. This kind of resin is always smooth, and is exported to India. Another variety, with an indented goose-flesh surface, known in the English market as *animé*, is dug from the earth, and, though the product of forests now extinct, originated probably from the same tree, as specimens of the recent gum, which had dropped from the tree, and been some time buried in the sand, present similar surface marking, and in other respects exhibit similar physical properties. (*Pharm. Journ.*, May, 1869, p. 654.) In papers contained in the *Pharm. Journ.* (xvi. 369 and 423), Dr. W. F. Daniell has given an account of several varieties of copal produced on the coast and interior parts of Western Africa, from Sierra Leone to Angola and Benguella, and exported in large quantities. Those from Sierra Leone, which are most highly valued for their superior hardness and transparency, are said by Dr. Daniell to be derived from the *Guibourtia copallifera* of Bennett, a large tree, growing preferably in mountainous regions, and very nearly related, botanically, to the Hymenææ, which produce copal in other regions. The drug is mostly collected, not from the tree itself, but from the beds and borders of streams, into which it is washed down, during the rains, from the hillsides, in the soil of which it had been deposited. Copal varies in appearance and properties as procured from different sources. It is in roundish, irregular, or flattish pieces, often rough over the surface, probably from the impression of sand in its soft state, colourless, yellowish, or brownish-yellow, more or less transparent, very hard, with a shining, conchoidal fracture, inodorous and tasteless, of a sp. gr varying from 1·045 to 1·139, insoluble in alcohol, soluble in ether and slightly so in oil of turpentine. Some varieties unite with alcohol, if suspended in its vapour while boiling. By heat it melts and is partially decomposed, becoming thereby soluble in alcohol and oil of turpentine. It is not a proximate principle, but consists of various resins united in different proportions. The East India or African copal is described by Mr. Schindler as of a globular form, softer and more transparent than the other varieties, with a

surface always clear, and having an agreeable smell when heated. It is readily and freely dissolved by the oils of turpentine and rosemary when pure, but not by these fluids when rendered resinous by age. It is more readily fusible than the others, and makes the best varnish. The West India copal is in flat pieces, seldom weighing more than three ounces, rarely containing insects, very hard, of a rough appearance, of a yellowish colour, and without smell or taste. It is much less readily dissolved by oil of turpentine than the East India variety, swells, but does not dissolve in oil of rosemary, and is slightly soluble in absolute alcohol. A third kind, probably also American, is in convex or concave pieces, about a pound in weight, often containing insects and other impurities. In solubility it resembles the last mentioned variety, in fusibility is intermediate between it and the East Indian, and is altogether inferior. (*Pharm. Journ.*, Aug. 1850.) The *African or Sierra Leone copal* is described by Dr. Daniell as occurring "in small round tears, or irregular conical and smooth nodulated masses, seldom exceeding in size an ordinary duck egg. They are covered, to a greater or less extent, by a peculiar white efflorescence, which increases by age. Their colour graduates from a pale-green to a lemon or dull-yellow." (*Ibid.*, xvi. 369.) Dr. Welwitsch, "in Notes and Observations on the subject of copal, made during his travels in West Africa," states that this drug is mostly found in sandy soil, in the hilly districts, along the whole coast of Angola, where its prevalence coincides with that of *Adansonia digitata*. It is dug from the earth, or found in spots where it has been collected by the washing of the rains, or laid bare by earth-falls; and the quantity annually collected in this region, and exported from Benguella, from 1850 to 1860, was 1,600,000 pounds. The surface, like that described by Dr. Daniell, is covered with a whitish earthy crust, sometimes exhibiting veins or network, probably produced by attrition in their conveyance by floods from their original site. (*Am. Journ. of Pharm.*, Sept. 1866, p. 439; from *Gardener's Chronicle.*) *Crude* and *scraped* copal are also known in the market; the former of a dull opaque appearance externally, the latter much clearer and more transparent, in consequence of being deprived of its outer coat. The process of *scraping* is said to consist in the removal of the exterior portion by means of an alkaline solution, which readily dissolves copal. This resin is used chiefly in making varnishes. For a paper by M. H. Violette on the preparation of copal varnish, see the *American Journal of Pharmacy* (March, 1863, p. 140). M. Violette states that certain varieties of copal used for varnish, which are not naturally soluble in ether, oil of turpentine, benzine, petroleum, &c., become soluble in these menstrua, whether cold or hot, by being heated in close vessels to the temperature of 350° to 400°, and thus yield excellent varnishes without loss of matter; and the same resin, heated as above with one-third of linseed oil and three-fourths of oil of turpentine, gives directly a clear, limpid, slightly yellowish varnish, fit for the most delicate uses. (*Journ. de Pharm.*, 4e sér., iv. 284.) W.

COPPER, BLACK OXIDE OF. This is the protoxide of copper, CuO, obtained most conveniently by heating to redness the nitrate. This oxide, in the form of ointment, made by mixing four parts with thirty of lard, has been used in frictions, practised twice a day, for the removal of chronic indurations of the glands. (Hoppe, *Ann. de Thérap.*, 1855, p. 251.) B.

CORAL. A substance found at the bottom of the Mediterranean and other seas, formerly considered as a plant, but now universally admitted to belong to the animal kingdom. The *red coral* (*Corallium rubrum* of Lamarck, *Isis nobilis* of Linn.) is in the form of a small shrub, a foot or two in height, with a stem sometimes an inch or two in thickness, fixed to the rock by an expansion of the base, divided above into branches, and covered with a pulpy membrane, which is properly the living part, and which is removed when the coral is collected. The central portion is extremely hard, of various shades of red, susceptible of a brilliant polish, longitudinally striated, and formed of concentric layers, which are rendered obvious by calcination. Its chief constituent is carbonate of lime, which is coloured by oxide of iron, and united, as in similar calcareous products, with more or less animal matter. It was formerly highly esteemed as a remedy, but is in no respect superior to prepared oyster-shell, or other form of carbonate of lime, derived from the animal kingdom. It was employed in fine powder, or in different preparations, such as troches, syrups, conserves, &c. At present it is valued chiefly as an ornament. W.

CORALLINE. *Pœonin.* A colouring or dyeing material, derived from *rosolic acid*, which is itself derived from *carbolic* or *phenic acid*, by its oxidation. It is formed by exposing together rosolic acid and ammonia to a heat of 300° F. A solid substance is thus obtained, in scales of a peony redness, with reflected green or dull-yellow rays, almost insoluble in water, soluble in alcohol and the fixed oils, and having all the characters of an amide acid. Dr. Ambrose Tardieu, having met with some extraordinary cases of a severe vesicular eruption upon the feet, attended with violent inflammation and swelling, and with general febrile symptoms; and having been disposed to ascribe the affection to the poisonous properties of the colouring matter contained in a red silk, out of which socks, slippers, stockings, &c., worn by the sufferers, had been made, resolved to determine the accuracy of his impressions by experiment. He first satisfied himself that the suspected material contained no mineral substance, and then, aided by a chemist, M. Z. Roussin, proceeded to search for some organic principle to which the effects might be traced. The red silk socks, to which the eruption in the first case that occurred to him was ascribed, were first treated by water in different states; cold, hot,

feebly acidulated, and alkaline; but yielded nothing to the menstruum. They were then immersed in boiling alcohol of 85°, which quickly dissolved the red colouring matter. By evaporating the alcoholic solution thus made, an extract was obtained, which, on being injected in alcoholic solution into the areolar tissue of a dog, rabbit, and frog, produced death in all, in the frog in 4 hours, in the dog after 36 hours, and the rabbit later; the two latter animals having been copiously and almost incessantly purged. The colouring matter was thus shown to be very poisonous. To determine whether the poisonous colouring material was coralline, as they suspected, some of this substance was obtained from M. Persoz. Three varieties of coralline were presented; one pure, the other the coralline red of commerce, and the third coralline yellow. It was with the pure coralline that they operated. An alcoholic solution was injected into animals as before, with the same result. A dog was killed by 20 centigrammes (about 3 grains), a rabbit by half the quantity, and a frog by 5 centigrammes, or less than a grain. In the dog and rabbit, there was violent purgation, with intense fever and progressive prostration, and the leg of the side in which the injection had been made was very painful. After death the neighbourhood of the wound was found suppurating, the stomach sound, and the intestines distended, with signs of violent inflammation of the mucous membrane; the liver presented evidences of fatty degeneration; and the lungs appeared as if dyed by the colouring matter, exhibiting a very beautiful scarlet hue throughout their whole extent, and over their whole surface. M. Roussin succeeded in extracting a portion of the colouring matter from the lungs and liver, and dyeing with it a skein of silk. These experiments are very interesting in a medico-legal point of view; as coralline might be readily detected in this way, if at any time, accidentally or otherwise, the cause of fatal results. Hitherto the effects on the human subject have been confined to the painful cutaneous affection, which has been so satisfactorily traced to contact of the skin with the silk fabrics dyed with it; but, even in these cases, there were serious constitutional symptoms, as fever, headache, giddiness, and nausea, which probably proceeded in part from the absorption of the poison. (*Journ. de Pharm.*, Avril, 1869, p. 262.)

From a late communication by M. Tardieu, it appears that coralline is not the only colouring material capable of producing local poisoning; as red socks or stockings dyed with anilin red have given rise to accidents. These two colours may be distinguished in tissues. *Anilin red* disappears very rapidly by contact with ammonia; but the colour reappears by the addition of an acid, or by the evaporation of the alkali. *Coralline red* is not dissolved by cold water, yields a slight colour to boiling water, but rapidly disappears from the tissue under the action of boiling alcohol. Alkalies brighten the colour without changing it; acids precipitate the colouring matter in yellow flakes. (*Ibid.*, Mai, 1869, p. 371.)

Other cases of local poisoning from the wearing next the skin of silks dyed with coralline, or other similar matter, have been recorded in the journals, among which may be mentioned two described in the *Med. Times and Gaz.* (April, 1869, p. 421). W.

CORALLORHIZA ODONTORHIZA. (*Gray's Manual*, p. 453.) *Coral-root.* This is a leafless herb, sending up from a coral-like rhizoma, a simple scape or flower-stem, from 6 to 16 inches high, furnished with sheaths instead of leaves, of a light-brown or purplish colour, and bearing small, greenish-brown flowers in a long spike. The plant grows throughout the United States east of the Mississippi. It is supposed by some to be parasitic, attaching itself to the roots of trees, and nourished from them. The root or rhizoma is the part used. It is much branched and toothed, and of a brown colour, and from its resemblance to coral in appearance gave name to the plant. It has a strong peculiar odour, and an astringent bitterish taste. It holds a high place in the Materia Medica of the "eclectics," being considered by them as an energetic diaphoretic, and, as it is destitute of general stimulant properties, is given in fevers and inflammatory affections. It is administered in powder, in the dose of thirty grains, every two hours. W.

CORIARIA MYRTIFOLIA. *Redoul*, Fr. This is a shrub indigenous in the South of France, and growing also wild in Spain, Italy, and Barbary. It is sometimes cultivated in gardens on account of its handsome foliage. The leaves, which are used for dyeing black, were at one time employed to a considerable extent in France in the adulteration of senna. The fruit, resembling berries in form, are black, and about the size of a pea. Both these and the leaves are poisonous in large doses, and several instances of death are on record from eating the fruit. They are supposed to act as a narcotic, as a child under their influence appeared, half an hour after taking them, as if in a state of drunkenness, with loss of speech, foaming at the mouth, livid face, and convulsive movements, and died at the end of 17 hours. The stomach upon examination showed scarcely any signs of phlogosis. (*Mérat et De Lens.*) M. Riban has discovered in the fruit a peculiar principle, on which he believes their poisonous properties depend, and to which he has given the name of *coriamyrtin*. This is in the form of white crystals, inodorous, excessively bitter, and extremely poisonous. It is but slightly soluble in water hot or cold, but freely so in alcohol, ether, chloroform, and benzole. Its composition is represented by the formula $C_{40}H_{28}O_{16}$. It ranks with the glucosides. About three grains of it killed a dog, first vomiting, then causing severe convulsions, and death in an hour and a quarter. M. Riban obtained it by treat-

ing the juice of the fresh or an infusion of the dried fruit and leaves first with acetate of lead, then with sulphuretted hydrogen to throw down the lead, concentrating the filtered liquid to a syrupy consistence, and agitating this with ether, which extracted the poison, and yielded it on evaporation. (*Journ. de Pharm.*, Juin, 1864, p. 487.)

Toot-poison. In New Zealand a poisonous plant, known as the *toot-plant*, has proved very destructive to the domestic animals of the settlers. Dr. W. Lauder Lindsay, in a journey through New Zealand, had an opportunity of examining the plant and its effects. He found it to be the *Coriaria ruscifolia* of Linnæus (*C. sarmentosa*, Forst.), and in its action on the system to be an irritant narcotic. For an elaborate account of the *toot-plant*, and its poisonous effects, the reader is referred to papers by Dr. Lindsay in the *British and Foreign Medico-chirurgical Review* (July, 1865, p. 153, and Octob. 1868, p. 465). From these it appears that more than one species of Coriaria inhabit New Zealand; *C. thymifolia*, and *C. angustissima*, besides the *ruscifolia*; though Dr. Lindsay appears to think that the two former may be merely varieties of the third; as the species of the genus are very variable; and the three indigenous in New Zealand pass into each other by gradations. It is not only cattle that are poisoned by the plant; but not unfrequently also children, who are apt to eat the fruit, and occasionally even an adult. The cattle are probably in general poisoned by eating the young shoots. It has been conjectured that the same narcotic principle found in C. myrtifolia (*coriamyrtin*) is that which renders the New Zealand species poisonous. The prominent symptoms of the poisoning in man are giddiness, stupor, and coma with or without delirium or convulsions. Occasionally the delirium resembles that of alcoholic intoxication, in other instances approaches that of acute mania, and is attended with violent muscular action. The loss of memory is one of the characters of convalescence. W.

CORK. *Suber*, Lat. *Liege*, Fr. The great use made of this substance by the apothecary will justify a brief notice of it here. Though in general ascribed exclusively to the *Quercus Suber*, a large oak growing in Spain, the South of France, North of Italy, Algeria, and some of the Mediterranean islands, it is said by M. Cassimer de Candolle to be obtained also for commercial purposes from another species, the *Q. occidentalis*, growing in the South-west of France and in Portugal. It consists of the exterior layers of the bark beneath the epidermis, which acquire in these species an extraordinary development, becoming thick, and of that peculiar spongy consistence which characterizes cork. The tree begins to yield cork when fifteen or sixteen years old, and every six or eight years furnishes a fresh supply, even for a century and a half, before it perishes; that interval of time being required for the renewal of the suberose layers by the living portions of the bark beneath. There are four constituent layers of the bark, the epidermis, within this the cork, next the cellular envelope, and lastly the liber which lies upon the wood. Each of these increases year by year; but the cork thus naturally produced is not valued. The commercial product is obtained by an artificial process. The exterior layers are removed, and the liber exposed. In the interior of this, at a variable distance from the surface, a layer of the proper cork is now formed, apparently by a change in the substance of the liber, the outer portions of which perish, while annually a new layer is added to the cork already existing, until it acquires a thickness which will justify its removal. Incisions are made in such a way that the cork is removed in large concave plates, which are then flattened under pressure, and dried very slowly. From ordinary accounts, it might be supposed that the cork-tree was very common in Spain; but in a long journey through that country from the North to the extreme South, the author had no opportunity of seeing the trees from which the cork was obtained except in the Eastern Pyrenees, where it appeared to be abundant.

In selecting cork for use, those parts should be preferred which are soft and of uniform consistence; and in the choice of the larger plates those should be selected which are thick, flexible, elastic, and finely porous, and of a reddish colour. (*Guibourt.*) Cork consists mainly of a peculiar proximate principle analogous to lignin, but differing from it in this respect, that, when treated with nitric acid, it yields a peculiar acid, which has been denominated the *suberic acid*. According to M. Chevreul, who has analyzed cork, it contains, besides the principle mentioned, a little volatile oil and acetic acid which it yields by distillation; a yellow colouring substance, an astringent principle, an animalized substance, gallic acid, another acid, gallate of iron and lime, all of which it yields to water; a wax-like crystallizable matter, a soft resin, and two other undetermined bodies, which were extracted by alcohol after the cork had been exhausted by water; altogether constituting about 30 per cent., while the characteristic ingredient mentioned, which may be called *suberin*, amounts to 70 per cent.

M. Stanislaus Martin has called attention in France to the use of refuse corks in Paris where they are collected by the scavengers, and sold to persons whose business it is to revive them; recutting such as are of unsuitable shape, filling up the vacuities with mastic, and covering them over with some powder which may give them a fresh and proper appearance. In consequence of the high price of cork, those which are thus prepared over again are said to be used in the bottling of beverages; and, as they have often been in contact with substances likely to act injuriously on the system, and may have become more or less deleteriously impregnated, their employment in this way may sometimes lead to injurious consequences. It is, for example, easy to conceive that a cork, at

one time used to enclose arsenical solutions, may become saturated with the poison, and afterwards impart enough of it to another liquid, if not to produce dangerous effects on the health, at least to give to tests evidence of its presence, and thus lead to serious suspicions. The subject appears worthy of attention, in order that we may be guarded from any possible evil from this source. W.

CORTEX CARYOPHYLLATA. *Cassia Caryophyllata. Clove Bark.* These names have been given to a bark, brought from the West Indies, and derived from a tree belonging to the family of Myrtaceæ, supposed to be the *Myrtus acris* of Schwartz. It is usually in cylinders from one to two feet long by an inch in diameter, composed of numerous separate pieces rolled around one another, having a dark-brown colour, a pungent taste, and an odour similar to that of cloves. It is sometimes in fragments, of a similar colour, taste, and smell, but softer and lighter, and supposed to be derived from older branches. A similar bark is said to be derived from the *Myrtus caryophyllata* of Linn., which grows in Ceylon. The clove bark has aromatic properties not unlike those of the spice from which it derived its name; but it is much inferior, and is not used in this country. Some authors have confounded with it a different bark, produced in the Moluccas, and known by the Indian name of culilawan. (See *Culilawan.*) W.

CORYDALIS FORMOSA. (*Pursh.*) *Turkey Corn. Turkey Pea.* This pretty little indigenous plant, growing in the Middle and Western States, is one of those employed by the practitioners calling themselves eclectics, and is highly esteemed by them. The root is the part used. It is a small roundish tuber, having a slight peculiar smell, and a bitterish somewhat pungent and persistent taste. It is said to yield its active properties to water and alcohol. According to Mr. W. T. Wenzell, who examined the root chemically, and made it the subject of an inaugural essay presented to the Philadelphia College of Pharmacy, it contains an alkaloid denominated *corydalia*, fumaric acid, bitter extractive, an acrid resin with volatile oil, a tasteless resin, brown colouring matter, starch, albumen, arabin, bassorin, cellulose, and various inorganic salts. The alkaloid was obtained by making a hydro-alcoholic tincture, distilling off the alcohol, filtering, precipitating with ammonia in slight excess, washing the precipitate, treating it with boiling alcohol, evaporating the solution to dryness, treating the residue with dilute muriatic acid, precipitating with ammonia, dissolving the precipitate in boiling alcohol, concentrating the tincture, and allowing it to stand. The corydalia was deposited in crystals, and was purified by repeated solution in alcohol and crystallization. The crystals, which are slender four-sided prisms, are inodorous, tasteless, insoluble in water, soluble in alcohol, ether, and chloroform, reddened by nitric acid, and capable of forming soluble salts with the acids. It appears to be identical with the alkaloid found in European species of Corydalis. This has been examined by G. Leube, who gives, as the result of his analysis, the formula $C_{46}H_{29}NO_7$, as representing its composition.

The corydalin of the *Corydalis tuberosa*, of Europe, was discovered in 1826 by Wackenroder. Wicke obtains it from the tubers by heating their watery infusion acidulated with sulphuric acid to 120° F., precipitating with phospho-tungstate of soda (made by treating metatungstate of soda with sufficient phosphate of soda to prevent turbidness from acids), washing the yellowish precipitate, then treating it, hot, with chalk rubbed up with water, evaporating by a water-bath, and exhausting with alcohol. The solution, after evaporation, deposits, on standing, a portion of the alkaloid in star-shaped prisms. It is soluble in alcohol, ether, chloroform, amylic alcohol, sulphuret of carbon, benzine, and oil of turpentine. The alcoholic solution has a bitter taste and alkaline reaction. Corydalin forms crystallizable salts with muriatic, acetic, and other acids. It is precipitated by tannic acid, and white by sulpho-cyanide of potassium, bichloride of mercury, iodide of potassium, and metatungstate of soda, and yellow by picrate of soda, chromate of potassa, iodohydrargyrate of potassium, and the chloride of gold and platinum. (*Journ. de Pharm.*, 4e sér., iii. 395.)

The root of C. formosa is supposed to be tonic, diuretic, and alterative, and is given in syphilitic, scrofulous, and cutaneous affections, in the dose of from ten to thirty grains. It is also used in the form of tincture and decoction. We are indebted for the above abstract of the properties and uses of this plant to the essay of Mr. Wenzell, above referred to, published in the *American Journal of Pharmacy* for May, 1855, p. 205. The "eclectics" use a preparation which they call *corydalin* or *corydalia* made by precipitating a tincture of the root with water, in the dose of half a grain or a grain. It is of course not the active principle, and therefore has no claim to the title; yet it no doubt contains more or less of the proper alkaloid. W.

CORYLUS ROSTRATA. *Beaked Hazel.* This is a small indigenous shrub, growing especially in mountainous districts. The nut is invested with a scaly involucre, projecting beyond it like a beak, and thickly covered with short spicula like those of Mucuna pruriens. These spicula have been employed by Dr. Heubener, of Bethlehem, Pennsylvania, as an anthelmintic, and found to be efficacious. They operate in the same way as cowhage, and may be administered in the same manner and dose. (See a communication by the late Mr. Duhamel, in the *Am. Journ. of Pharm.*, xiv. 280.) W.

COTYLEDON UMBILICUS. *Navel-wort. Penny-wort.* This is a perennial, herbaceous, succulent plant, belonging to the class and order Decandria Pentagynia, and the natural family of Crapulaceæ. It is about six inches high, with fleshy, peltate, crenate leaves, and a flower-stem bearing, in the form of a spike, pale-yellow, bell-shaped, pendulous flowers, which appear in June and July. The plant is a native of England, where it grows upon old walls and rocks, and dry sandy banks. It was first brought before the profession, as a remedy in epilepsy, by Mr. Thos. Salter, of Poole, who had found its expressed juice very efficient in that disease, and published the results of his observations in the *London Medical Gazette* for March, 1849 (*page* 367). In the following May, Dr. Joseph Bullar, of Southampton, communicated the results of his observations on the same subject to the *Prov. Med. and Surg. Journ.*, which were confirmatory of those of Mr. Salter. Since that period, other testimony has been advanced in favour of the remedy; among which is that of Dr. Graves, of Dublin, who considers it a valuable aid in the treatment of epilepsy, and states that it has long been known in Ireland as a popular remedy, not only in that disease, but in asthma. (*Dublin Quart. Journ. of Med. Sci.*, xiv. 264.) It is, however, proper to say that Dr. Ranking, of Norwich, England, in a letter published in the *Lond. Med. Times and Gaz.* for April, 1854 (*page* 328), declares that, so far as his experience goes, he considers the medicine utterly worthless, having employed it perseveringly in more than thirty cases of epilepsy, without the smallest benefit in a single instance.

The medicine is said to have no other observable effect than that of a gentle tonic to the nervous system. The part used is the expressed juice, which should be obtained when the leaves are most succulent, before the appearance of the flowers. An extract, and a fluid extract have also been employed. The juice has been given in doses varying from a fluidrachm to a fluidounce twice or three times a day, and should be long persevered with. The dose of the fluid extract is stated at a fluidrachm, that of the dry extract at five grains, to be increased if necessary.

The probability of medicinal inertness arising from the absence of any positive physical characters in this plant can now scarcely be urged against it. From the researches of M. Flétet, it appears to contain a principle analogous to propylamin, at one time thought to be identical with it, yet now admitted to be distinct, though isomeric with it; namely *trimethylamin*, which exists in it, combined with a yet unknown acid. When the powder of the plant is exposed to the air, it attracts moisture, and exhales a disagreeable smell strikingly analogous to that of fish; and an extract, treated with a fixed alkali, disengages, even in the cold, an odour, which, at first ammoniacal, soon acquires the fishy character referred to. The presence of this ammoniacal compound, concurrently with that of a salt of ammonia, together with a notable portion of nitre, is sufficient to prove that the plant is not entirely inert, as it has generally been thought to be. We might expect in it virtues somewhat analogous to those of ergot, which owes a similar odour to propylamin. Besides this salt of trimethylamin, which, with an ammoniacal salt, constitutes 2 parts in 1000 of the plant, it contains cellulose, starch, glucose, mucilage, chlorophyll, yellow colouring matter, a volatile oil smelling like sandarac, tannin, iron, and salts of potassa, soda, lime, and oxide of iron, with 0·9 per cent. of nitre, and 95 of water. (*Ann. de Thérap.*, 1865, p. 125.) With this account of the chemical character of the plant, we are prepared to receive without absolute incredulity, the statement of M. Fonssagrives, who, having employed this remedy in a large number of epileptic cases, declares that some have been cured, and in almost all there has been a very observable amelioration, evinced in a diminished frequency and intensity of the attacks. The whole treatment consists in the daily use of a tablespoonful of the juice, which is to be continued for a year at least. (*Ibid.*, 1868, p. 56; from *Gaz. Hebdomad.*) W.

CRABS' CLAWS. *Chelæ Cancrorum.* These, in a prepared state, were formerly included in the Edinburgh Pharmacopœia, but were very properly omitted upon the last revision of that work. Supposing them identical with the crust of the lobster, they consist, in the 100 parts, of 60 parts of carbonate of lime, 14 of phosphate of lime, and 26 of animal matter. They are prepared by levigation and elutriation, so as to bring them to a fine powder. They were formerly used as an absorbent and antacid; but the animal matter in their composition confers on them no peculiar virtues. They are given in the same dose with prepared chalk. B.

CRABSTONES. *Lapilli Cancrorum. Crabs' Eyes.* These are concretions found in the stomach, one on each side, of the European crawfish, at the time the animal is about to change its shell. They are most abundantly procured in the province of Astracan, in Asiatic Russia. The crawfish are bruised with wooden mallets and laid up in heaps to putrefy. The animal remains are then washed away, and the stones picked out. They are inodorous, insipid bodies, somewhat hemispherical in shape, of a white or reddish colour, hard and stony consistence, and laminated texture. They are very variable in size, weighing from one to twelve grains each. They effervesce with acids, and, without dissolving, become converted, owing to the animal matter which they contain, into a soft transparent mass, retaining the original shape of the stone. By this character they are distinguished from counterfeit stones, which are sometimes fabricated of chalk, mixed with mucilaginous substances. They consist of carbonate and phosphate of lime, cemented together

by animal matter. Crabstones have been used as an absorbent and antacid, given in the same dose with prepared chalk. They were prepared by being levigated in the usual manner; but they are now no longer officinal, having been expunged from the Edinburgh Pharmacopœia. B.

CROCUS OF ANTIMONY. *Saffron of Antimony.* This compound is formed during the deflagration of a mixture of equal weights of tersulphuret of antimony and nitrate of potassa, to which one-twelfth of muriatic acid has been added. The nitric acid of the nitre is decomposed, nitrogen and nitric oxide being given off, and, by furnishing oxygen to part of the tersulphuret, converts its constituents into sulphuric acid and teroxide of antimony. The sulphuric acid combines with the potassa of the nitre, to form sulphate of potassa; while the teroxide unites or mixes with the undecomposed tersulphuret to constitute the crocus. The muriatic acid prevents the formation of sulphuret of potassium and free potassa, by giving rise to chloride of potassium. The product of the deflagration is reduced to powder, washed with boiling water to separate sulphate of potassa and chloride of potassium, and then fused. When crocus of antimony is intended to be employed for making tartar emetic, it should not be fused; because it requires, for preparing this antimonial, to be reduced to a very fine powder, and the fused substance is pulverized with difficulty. The deflagrated mass, instead of being fused should be reduced to very fine powder, and washed with boiling water. In this state it more readily dissolves in the solution of cream of tartar. Fused crocus is in masses of a liver-brown colour. As obtained without fusion, it is a saffron-brown insoluble powder, containing about four-fifths of its weight of teroxide, the remaining fifth being tersulphuret. In the London Pharmacopœia of 1836, the unfused crocus was adopted for preparing tartar emetic; but in the edition of 1851 it was abandoned, and the subsulphate of antimony substituted for it. B.

CUCUMBER OINTMENT. An emollient ointment, prepared from the common cucumber (fruit of *Cucumis sativus*), has been considerably employed in irritated states of the skin. The following is the mode of preparing it, recommended by Prof. Procter. Take of green cucumbers 7 pounds avoirdupois, pure lard 24 ounces, veal suet 15 ounces. Grate the washed cucumbers to a pulp, express, and strain the juice. Cut the suet into small pieces, heat it over a water-bath till the fat is melted out from the membrane; then add the lard, and, when melted, strain through muslin into an earthen vessel capable of holding a gallon, and stir until thickening commences, when one-third of the juice is to be added, and the whole beaten with a spatula till the odour has been almost wholly extracted. The portion which separates is to be decanted, and the remaining two-thirds of the juice are to be consecutively incorporated and decanted in the same manner. The jar is then closely covered and placed in a water-bath, until the fatty matter entirely separates from the juice. The green coagulum floating on the surface is now removed, and the jar put in a cool place that the ointment may solidify. The crude ointment is then separated from the watery liquid on which it floats, melted and strained, and placed in glass jars, which must be kept closely sealed. A layer of rose-water upon its surface will favour its preservation. A portion may be triturated with a little rose-water until white and creamy, and put into a separate jar for present use. (*Am. Journ. of Pharm.*, xxv. 409.)

M. Emile Mouchon prepares the ointment by obtaining the juice mixed with a little alcohol, and incorporating this with benzinated lard and stearin. He directs 16 parts of the cucumber to be reduced to a pulp, 1 part of alcohol of 36° B to be added, and the mixture to be placed on the diaphragm of a percolator. Twenty-four hours afterwards 10 parts of the liquid are obtained of 19° B. Of this liquid 6 parts are to be incorporated with 37·5 parts of benzinated lard and 12·5 of stearin; the fatty matters having been previously melted together by means of a water-bath, and beaten vigorously on cooling. The liquid is to be added before the completion of the beating, which should then be continued until the whole becomes as light and white as possible. The benzoin and alcohol enable the ointment to keep a long time. (*Journ. de Pharm.*, Juillet, 1854, p. 41.) W.

CUCURBITA CITRULLUS. *Watermelon.* The seeds of the watermelon are employed, to a considerable extent, as a domestic remedy in strangury and other affections of the urinary passages. They have similar properties with the seeds of the other Cucurbitaceæ, of which four different kinds were formerly officinal under the name of the *greater cold seeds*—viz., those of the *Cucurbita Pepo* or pumpkin, the *Cucurbita Lagenaria* or gourd, the *Cucumis Melo* or muskmelon, and the *Cucumis sativus* or cucumber. These, when bruised and rubbed up with water, form an emulsion, which was formerly thought to possess considerable virtues, and was much used in catarrhal affections, disorders of the bowels and urinary passages, fever, &c.; but they have been superseded by other more agreeable demulcents. Watermelon seeds are also esteemed by some diuretic. They are given in infusion, made with one or two ounces of the bruised seeds to a pint of water, and taken *ad libitum*. The juice of the melon itself is undoubtedly diuretic, and might be very properly recommended as an adjuvant to other remedies in many cases of dropsy.

The pulp of the root of *Cucurbita Lagenaria*, or gourd, is said by Dr. Chapin to be a powerful and even drastic purgative, and to be used by the natives of the Sandwich Islands successfully in dropsy; though in the large quantities in which it is used by them, it sometimes proves fatal through hypercatharsis. (See a paper by Dr. Luther H. Gulick, in the *N. Y. Journ. of Med.* for March, 1855, p. 203.) W.

CULILAWAN. *Cortex Culilaban.* An aromatic bark, produced by *Cinnamomum Culilawan* (*Laurus Culilawan*, Linn.), a tree of considerable size, growing in the Molucca Islands, Cochin-China, and other parts of the East. It is usually in flat or slightly rolled pieces, several inches long, an inch or more in breadth, and one or two lines thick. Sometimes the bark is thinner and more quilled, bearing considerable resemblance to cinnamon. The epidermis is for the most part removed, but when present is of a light brownish-gray colour, soft to the touch, and somewhat spongy. The colour of the bark itself is a dull dark cinnamon-brown, the odour highly fragrant, the taste agreeably aromatic, and not unlike that of cloves. The active constituent is a volatile oil, which may be separated by distillation. Culilawan has the medical properties common to the aromatics, but is scarcely used at present. W.

CUMIN SEED. CYMINUM, *Lond.* CUMINUM, *Ed.* Cumin seeds have been omitted in the British Pharmacopœia, and, having no place in our own, and consequently none in *Part* I. of this work, require a brief notice here. They are the fruit of the *Cuminum Cyminum*, an umbelliferous plant, belonging to Pentandria Digynia of the Linnæan system, with the following generic character. "*Fruit* ovate, striated. *Partial umbels* four. *Involucres* four-cleft." (*Willd.*) It is an annual plant, about six or eight inches high, having a round, slender, branching stem, with numerous narrow, linear, pointed, smooth, grass-like leaves, of a deep-green colour. The flowers are white or purple, and disposed in numerous terminal umbels, which have very few rays, and are attended with general and partial involucres, consisting of three or four linear leaflets. The fruit consists of two oblong plano-convex half-fruits, commonly called seeds, united by their flat sides. The plant is a native of Egypt, but is cultivated for its fruit in Sicily, Malta, and other parts of Europe.

The cumin seeds of the shops are elliptical, flat on one side, convex, furrowed, and rough on the other, about one-sixth of an inch in length, and of a light-brown colour. Each has seven longitudinal ridges. Two seeds are sometimes united together as upon the plant. Their odour is peculiar, strong, and heavy; their taste warm, bitterish, aromatic, and disagreeable. They contain much essential oil, which is lighter than water, yellowish, and has the sensible properties of the seeds. It consists of two distinct oils, one a carbohydrogen, called *cymene* ($C_{20}H_{14}$), the other consisting of carbon, hydrogen, and oxygen ($C_{20}H_{12}O_2$), which may be regarded as *hydruret of cumyl* ($C_{20}H_{11}O_2,H$). (Gregory's *Organic Chemistry*, 4th ed., pp. 156 and 341.) In medical properties cumin seeds resemble the other aromatic fruits of umbelliferous plants, but are more stimulating. They are seldom used in the United States, and appear to have been retained by the London College merely as an ingredient in a stimulant and discutient plaster (*Emplastrum Cymini*), now no longer officinal. The dose is from fifteen grains to half a drachm. W.

CUNILA MARIANA. *American Dittany.* A small indigenous perennial herb, growing on dry, shady hills, from New England to Georgia, and flowering in June and July. The whole herb has a warm pungent taste, and a fragrant odour, dependent on an essential oil. By means of distillation with water, this oil has been separated by Mr. Philip Milleman, of Chicago, who describes it as of a reddish-amber colour, becoming light-yellow by exposure to light, of a delicate fragrant odour, very similar to that of oil of monarda, of a warm, pungent taste, and of the sp. gr. 0·920. It is readily soluble in alcohol, ether, and chloroform. On spontaneous evaporation, it leaves a small crystalline residue. Iodine decomposes it, producing white vapours; by sulphuric acid it is reddened and decomposed, by nitric acid resinified, and by muriatic acid decolorized, though its colour returns on exposure. It is slightly rubefacient; in the dose of five or ten drops is carminative, and of 15 to 20 drops diaphoretic. The same author found in the dried herb tannic acid, a trace of glucose, gum, bitter extractive, resin, and salts of potassa, lime, magnesia, and iron. (*Am. Journ. of Pharm.*, Nov. 1866, p. 495.) American dittany is a gently stimulant aromatic, analogous to the mints, pennyroyal, &c. In warm infusion, it is popularly employed to excite perspiration in colds and slight fevers, to promote suppressed menstruation, to relieve flatulent colic, and for various other purposes to which the aromatic herbs are thought applicable. W.

CUTTLE-FISH BONE. *Os Sepiæ.* This is a calcareous body, situated underneath the skin, in the back of the *Sepia officinalis*, or *cuttle-fish*, which inhabits the seas of Europe, especially the Mediterranean, in the waters of which the bone is not unfrequently found floating. It is oblong-oval, from five to ten inches long, and from one and a half to three inches broad, somewhat convex on both sides, with thin edges, of a rather firm consistence upon the upper surface, very friable beneath, and composed of numerous layers, loosely connected, so as to give to the mass a porous consistence. It is lighter than water, of a white colour, a feeble odour of sea plants, and a saline taste. It contains, according to John, from 80 to 85 per cent. of carbonate of lime, besides animal matter, a little common salt, and traces of magnesia. Reduced by levigation and elutriation to a fine powder, it may be given as an antacid like chalk or oyster-shell. It is sometimes used as an ingredient of tooth-powders. Small pieces of it are often put into bird-cages that the birds may rub their bills against them; and the powder is employed for polishing. Another product of the cuttle-fish is a blackish-brown liquor, secreted by a small

gland into an oval pouch, communicating externally near the rectum by a long excretory duct, through which the animal is said to have the power of ejecting it at will. This, when taken from the fish, is dried, and used in the preparation of the water colour called *sepia.* W.

CYANIDE OF ZINC. *Zinci Cyanidum. Cyanuret of Zinc.* This cyanide is precipitated as a white insoluble powder, by adding cautiously, until it ceases to produce a precipitate, a recently filtered solution of cyanide of potassium, obtained from the impure black cyanide, to a solution of sulphate of zinc. It is used in Germany as a substitute for hydrocyanic acid, and is said to be anthelmintic. It has been employed in epilepsy, chorea, and neuralgia, in several painful affections of the stomach, and in the colics attendant on difficult menstruation. The dose is a quarter of a grain, gradually increased to a grain and a half, given in mixture. It is included in the officinal list of the French Codex. B.

CYCLAMEN EUROPÆUM. *Pain de Pourceau*, Fr. *Sow-bread.* This is an herbaceous perennial, stemless plant, indigenous in the South of Europe, and cultivated in gardens for the beauty of its purple flowers, with reflected petals. It belongs to *Pentandria Monogynia* of the Linnæan system, and to the natural order *Primulaceæ.* The root is globular, with many branched fibres, almost black without, and white within, inodorous, and, when fresh, of a bitter, acrid, burning taste. By drying it loses much of its acrimony, and is said to be rendered edible by roasting. Hogs are said to root it up from the ground and to eat it with impunity; and hence its common French name. The root is a drastic cathartic, and is thought to have the power of producing abortion, for which purpose it is sometimes employed among the peasantry, who habitually use it as a cathartic. Sometimes, however, it has produced very serious effects, as inflammation of the alimentary canal, with bloody stools, cold sweats, and convulsive movements, which have even ended fatally. It is supposed to be capable of acting on the bowels when applied to the skin; and, in the form of ointment, is said to be rubbed on the surface of the abdomen in children for the expulsion of worms. (*Mérat et De Lens.*) The root probably owes its acrimony, if not all its medicinal properties, to an active principle, first discovered many years since by Saladin, and named by him *arthanitin*, and more recently by S. De Luca, who has given it the more appropriate name of *cyclamin.* It is white, amorphous, inodorous, and, when held a short time in the mouth, intensely acrid, extending its action even to the throat. With cold water it swells and becomes gelatinous, but is readily dissolved, and forms a solution which froths like soap and water, and is coagulated by a heat of about 150° F. Alcohol dissolves it with difficulty when cold, but freely when hot; it is soluble in glycerin with the aid of heat; and is insoluble in ether, chloroform, bisulphuret of carbon, and the essential oils. It contains no nitrogen; its formula being, according to an analysis by Dr. Klinger, $C_{28}H_{16}O_{12}$. Dr. T. W. C. Martius recommends the following method of preparing it. The tubers, collected in the autumn, dried, and powdered, are mixed with animal charcoal, and exhausted at a boiling heat by alcohol of 0·825; the tincture is filtered, concentrated, and set aside for six or eight weeks, when the cyclamin is deposited. This should be washed on a filter with alcohol till it passes colourless; and if the filtrate be concentrated, and set aside, it will deposit a further quantity in a few weeks. The whole is then mixed with animal charcoal, and treated with boiling alcohol, which will slowly deposit the pure cyclamin on cooling. This principle was found by M. De Luca, by experiments on animals, to be poisonous, and he supposed it to resemble curari in its action, though less violent. (See *Am. Journ. of Pharm.*, Jan. 1858, p. 21, and March, 1860, p. 154.) The dose of the powdered root is said to be from 20 to 40 grains. W.

CYNANCHUM VINCETOXICUM. R. Brown. *Asclepias Vincetoxicum.* Linn. *White Swallow-wort. Vincetoxicum.* A perennial herbaceous European plant, the root of which was formerly esteemed a counterpoison, and hence gave origin to the officinal name. It has a bitterish acrid taste, and, when fresh, a disagreeable odour, which is diminished by drying. Taken internally, especially in the recent state, it excites vomiting, and is capable, in larger quantities, of producing dangerous if not fatal inflammation of the stomach. Its former reputation as an alexipharmic was without foundation. It is said to be useful in cutaneous diseases, scrofula, &c., but is little employed. The leaves of the plant also are emetic. Feneulle found in the root a peculiar principle analogous to emetin. W.

CYNARA SCOLYMUS. *Garden Artichoke.* This is a perennial plant, indigenous in the South of Europe, and cultivated in our gardens as a culinary vegetable. The flowers, constituting what are commonly called the *heads*, are the part used. The receptacle and the lower portion of the fleshy leaflets of the calyx are eaten, and the other parts rejected. When young, the heads are cut up raw and eaten as salad; when older, they are boiled, and dressed variously. The flowers are said to curdle milk, and the plant to yield a good yellow dye. The leaves and their expressed juice are very bitter, and have been thought to be actively diuretic. They have long had some reputation in the treatment of dropsies. Dr. Badely, of Chelmsford, England, recommends a tincture and extract, prepared from the leaves, in rheumatic, gouty, and neuralgic affections. He gives

a drachm of the tincture, with five grains of the extract, three times a day, with or without other remedies, as circumstances seem to require. The leaves should be fresh and the preparations made from them quickly used. (*Lond. Lancet*, 1843, p. 556.) W.

CYNOGLOSSUM OFFICINALE. *Hound's Tongue.* A biennial plant, common both in Europe and this country, and named from the shape of its leaves. The leaves and root have been employed, but the latter has been generally preferred. The fresh plant has a disagreeable narcotic odour resembling that of mice, which is dissipated by drying. The taste is nauseous, bitterish, and mucilaginous. Different opinions as to its powers have been entertained, some considering it nearly inert, others as a dangerous poison. Dr. Diedülin, of St. Petersburg, Russia, affirms that an extract of this plant will paralyze the motor nerves in vertebrate animals; and J. Setschenow, of Gratz, states that, upon introducing a piece of the extract, about as large as the head of a pin, which he had received from Dr. Diedülin, into the dorsal lymph sac of each one of four frogs, he produced total paralysis of motion in from five to ten minutes; the heart continuing to beat, the irritability of the muscles continuing, and sensation remaining undisturbed. (See *Med. and Surg. Reporter*, Aug. 22, 1868, p. 153.) Hound's tongue has been used as a demulcent and sedative in coughs, catarrh, spitting of blood, dysentery, and diarrhœa; and has been applied externally in burns, ulcers, scrofulous tumours, and goitre. Should the plant be found really to possess the property assigned to it by Dr. Diedülin, it might be tried in tetanus with hope of benefit. The *pilulæ de cynoglosso*, which are officinal in some parts of Europe, though they contain the root of hound's tongue, owe their properties chiefly to opium. W.

CYTISUS LABURNUM. *Laburnum.* The laburnum is a small tree, indigenous in the higher mountains of Europe, and cultivated, throughout the civilized world, in gardens and pleasure grounds for the beauty of its flowers, which appear early in the spring in rich pendent yellow clusters. The young shoots and probably the leaves, indeed all parts of the plant, are purgative, and in excessive doses poisonous. Caventou found in the flowers an odorous fixed oil, gum, lignin, gallic acid, and traces of sulphate and muriate of lime. MM. Chevallier and Lassaigne discovered in the seeds a peculiar principle, to which they gave the name of *cytisin*. This was a yellowish-white, neuter, amorphous, deliquescent, non-nitrogenous substance, of a bitter nauseous taste, soluble in water and weak alcohol, and insoluble in ether. In small doses it produced, in several animals of different species, vomiting, convulsions, and death; and eight grains taken by Chevallier himself caused threatening symptoms, which disappeared under the free use of lemonade. Five grains appeared equal to three of tartaric emetic. (*Mérat et De Lens.*) Dr. Th. Scott Gray found in laburnum three distinct principles, an acid which he named *laburnic*, and two other substances, both of them bitter and neuter, which he proposed to call *laburnin* and *cystinea*. These are contained in variable proportions in all parts of the plant, but most largely in the bark and seeds. As all of them are soluble in water, and only a portion in alcohol, the former is the proper menstruum for extracting the virtues of the plant. Dr. A. Husemann claims to have discovered a new alkaloid in laburnum, which he calls *cytisin*, and describes as a white, crystalline solid, of a bitter somewhat caustic taste, soluble in water and alcohol, but scarcely at all soluble in ether, chloroform, benzole, or sulphuret of carbon. It is strongly basic, and has the composition $O_{20}H_{27}N_3O$, of course quite different from the cytisin of MM. Chevallier and Lassaigne. (*Chem. News*, July 16, 1869, p. 36.) In reference to the physiological effects of laburnum, Dr. Gray found that, after a slight excitement of the nervous and circulatory systems, there was a diminution of the pulse and a disposition to sleep. Decided narcotic effects were produced, with a moderate increase of urine, and a tendency to increased action of the liver. Dr. Gray employed the preparations of the plant therapeutically, and thought them useful in bilious dyspepsia, with periodical vomiting and alternations of constipation and diarrhœa; in infantile vomiting; in allaying the cough in bronchitis, and the violence of the paroxysms of hooping-cough and asthma; in the vomiting of pregnancy; and, finally, given in large doses four times a day, in the treatment of prurigo; the decoction being at the same time applied externally. (*Journ. de Pharm.*, Août, 1862, p. 160; from the *Ed. Med. Journ.*) Several cases of poisoning from laburnum seeds have been recorded. In a child about six years old, taken to the Cork Infirmary, the symptoms were giddiness and pain in the head, dryness and constriction of the throat, afterwards very painful sensations in the stomach, followed by nausea and vomiting, with rapid and fluttering pulse, laboured breathing, convulsive twitchings of the face, and wide dilatation of the pupils and insensibility to light. He recovered, however, under treatment. (J. Popham, *Dub. Quart. Journ.*, Feb. 1863, p. 248.) Another case is reported as having occurred at Canterbury, England, in which very similar symptoms resulted from the same cause, and with a similar result. (*Med. Times and Gaz.*, Sept. 13, 1862.) W.

DAJAKSCH. *Arrow Poison of Borneo.* This poison, which is in the form of an extract, but apparently of unknown botanical origin, was made the subject of experimental investigation by Dr. P. M. Braidwood, who came to the following conclusions as to its physiological action. 1. It causes death by paralyzing the heart, which is proved by the fact that, after ligature of the heart, death occurs in the same manner and in about the

same time as after taking this poison. 2. That the cessation of the heart's action results from paralysis of the cardiac ganglia of the great sympathetic. 3. That the other phenomena, such as paralysis of sensation and motion, are the natural results of paralysis of the heart. (*Edin. Med. Journ.*, Aug. 1864, p. 127.) It is not the same as the Java arrow poison, which is the product of the Upas Antiar, though this also destroys life by suspending the cardiac action. The Upas Antiar appears to act directly on the heart, the dajaksch through the sympathetic ganglia. (*Ibid.*, p. 133.) W.

DIANTHUS CARYOPHYLLUS. *Clove Pink.* The *clove pink* or *carnation* is too well known to require minute description. It is a perennial, herbaceous plant, belonging to the family of Caryophyllaceæ, and characterized as a species by its branching stem, its solitary flowers, the short ovate scales of its calyx, its very broad beardless petals, and its linear, subulate, channeled, glaucous leaves. Indigenous in Italy, it is everywhere cultivated in gardens for the beauty of its flowers, of which numerous varieties have been produced by horticulturists. Those are selected for medicinal use which have the deepest red colour, and the most aromatic odour. The petals should not be collected till the flower is fully blown, and should be employed in the recent state. They have a fragrant odour, thought to resemble that of the clove. Their taste is sweetish, slightly bitter, and somewhat astringent. Both water and alcohol extract their sensible properties, and they yield a fragrant essential oil by distillation. In Europe they are employed to impart colour and flavour to a *syrup*, which serves as a vehicle for other less pleasant medicines. According to the directions of the former Edinburgh Pharmacopœia, this was prepared by macerating one part of the flowers, without their claws, with four parts of boiling water for twelve hours, then filtering, and adding seven parts of sugar. W.

DIAPHORETIC ANTIMONY. *Antimonium Diaphoreticum. Potassæ Biantimonias* This compound is directed, in the French Codex, to be formed by deflagrating in a red-hot crucible, and keeping red-hot for half an hour, a mixture of pure antimony with twice its weight of nitrate of potassa, both being in fine powder. The product is washed with water and dried, and forms the *washed diaphoretic antimony*. As thus prepared, M. Oscar Figuier has shown that it contains, besides antimonic acid, both teroxide of antimony and antimonious acid; the nitre not being in sufficient quantity completely to peroxidize the antimony. When, however, the antimony is deflagrated with three times its weight of nitre, and the matter is kept at a red heat for an hour and a half, the whole of the antimony is converted into antimonic acid; and, when the product is thoroughly exhausted by boiling water, the resulting solution contains a large quantity of neutral antimoniate of potassa, and the insoluble residue is impure biantimoniate. M. Figuier rejects this residue, which forms the diaphoretic antimony of the ordinary process, and obtains the preparation from the solution of the neutral antimoniate, by passing through it a stream of carbonic acid gas, which removes one eq. of potassa from two of the antimoniate, and throws down the biantimoniate in the form of a white powder. By this process he obtained a quantity of the preparation, equal to three-fourths of the weight of the materials employed. Diaphoretic antimony is a perfectly white powder. When properly prepared, as by the process of M. Figuier, it consists of two eqs. of antimonic acid, one of potassa, and six of water. The dose is two or three drachms. On account of its weak and variable nature, it has been generally laid aside in practice. B.

DICTAMUS ALBUS. *White Fraxinella. Bastard Dittany.* This is a perennial European plant, the root of which is bitter and aromatic, and has been used as an anthelmintic, emmenagogue, and stomachic tonic; though at present little employed in Europe, and not at all in this country. Störck gave it in intermittents, worms, amenorrhœa, hysteria, epilepsy, and other nervous diseases. The bark of the root is the most active part. The dose is from a scruple to a drachm. W.

DIERVILLA TRIFIDA. (Mœnch, *Gray's Manual*, p. 166.) *D. Canadensis.* (Muhl.) *Bush Honeysuckle.* A low, erect, indigenous shrub, growing especially in rocky places throughout the Northern States. The whole plant, including root, branches, and leaves, is supposed to be possessed of diuretic and astringent properties, which render it useful, given in the form of infusion, in diseases of the urinary passages. It is one of the eclectic remedies. W.

DIOSCOREA VILLOSA. (*Gray's Manual*, p. 480.) *Wild Yam-root. Colic-root.* An indigenous perennial creeper, with long, branching, contorted, fibrous, ligneous roots. It grows from Maine to Wisconsin, and southward also. The roots are used by the "eclectics," who consider them efficacious in bilious colic. They are administered in decoction and tincture; and a substance called improperly *dioscorein*, obtained by precipitating the tincture with water, is used for the same purpose in a dose of from one to four grains. W.

DIPPEL'S ANIMAL OIL. *Oleum Cornu Cervi.* This oil is obtained during the distillation of bones, in the processes for obtaining ammoniacal products on a large scale. The portion which first comes over is pale yellow; but, in the progress of the distillation, the distillate becomes gradually deeper coloured and thicker, and at last black and viscid. It is purified and rendered colourless by redistillation, a pyrogenous resin being left

behind. Thus rectified it is a colourless liquid, very limpid and volatile, with a penetrating extremely fetid odour and burning taste. By repeating the distillation till a dark residuum is no longer left in the retort, it may be obtained free from fetor, and of an agreeable aromatic odour; and in this mode it is said to have been prepared by Dippel. Four or five distillations are necessary. (*Am. Journ. of Pharm.*, ix. 244.) The oil is soon altered by the action of air and light, becoming thick, yellow, brown, and finally black. It has an alkaline reaction, and probably contains the various principles which have been discovered by Reichenbach in the products of the distillation of organic substances.

This oil was originally obtained from hartshorn, and was a product of the decomposition of the gelatinous tissue, the horn containing no fat. When obtained from bones, it is a product of the same tissue; as these are boiled with a large quantity of water, and dried, before they are submitted to destructive distillation. The oily product of this distillation, after rectification, forms the *bone-oil* of commerce. Bone-oil has a dark-brown almost black colour, with a greenish shade. It is perfectly opaque in the mass, but brown when viewed by transmitted light in a thin layer. Its sp. gr. is about 0·970. Its smell is peculiarly disagreeable and somewhat ammoniacal. A piece of fir-wood, moistened with muriatic acid, and held over the mouth of a vessel containing it, acquires a dark reddish-purple colour, characteristic of *pyrrol*. It contains several organic bases, such as *petinin*, *picolin*, *&c.*, which have been examined by Dr. Thomas Anderson, of Scotland. (See his paper on the products of the distillation of animal substances, in the *Philos. Mag.*, 3d series, xxx. 174; and for a notice of picolin, see the note in *page* 676.)

Animal oil was formerly much used in medicine; but its repulsive odour and taste, as it is ordinarily prepared, have caused it to be almost entirely laid aside. It is given in the dose of a few drops, mixed with water, and acts as a stimulant and antispasmodic. Its presence in the spirit and salt of hartshorn gives to these preparations medicinal properties different from those of the pure spirit and of carbonate of ammonia. B.

DIRCA PALUSTRIS. *Leather Wood.* An indigenous shrub, usually very small, but sometimes attaining the height of five or six feet, growing in boggy woods, and other low wet places, in almost all parts of the United States. The berries, which are small, oval, and of an orange colour, are said to be narcotic and poisonous. The bark has attracted most attention. It is extremely tough, and of very difficult pulverization. In the fresh state it has a peculiar rather nauseous odour, and an unpleasant acrid taste, and when chewed excites a flow of saliva. It yields its acrimony completely to alcohol, but imperfectly to water even by decoction. In the dose of six or eight grains, the fresh bark produces violent vomiting, preceded by a sense of heat in the stomach, and often followed by purging. Applied to the skin it excites redness and ultimately vesicates; but its epispastic operation is very slow. It appears to be analogous in its properties to mezereon, to which it is botanically allied. W.

DRAGON'S BLOOD. *Sanguis Draconis.* This is a resinous substance obtained from the fruit of several species of *Calamus*, especially *C. Rotang* and *C. Draco*, small palms, growing in Siam, the Molucca Islands, and other parts of the East Indies. On the surface of the fruit, when ripe, is an exudation, which is separated by rubbing, or shaking in a bag, or by exposure to the vapour of boiling water, or finally by decoction. The finest resin is procured by the two former methods. It comes in two forms: sometimes in small *oval masses*, of a size varying from that of a hazelnut to that of a walnut, covered with the leaves of the plant, and connected together in a row like beads in a necklace; sometimes in *cylindrical sticks*, eighteen inches long and from a quarter to half an inch in diameter, thickly covered with palm leaves, and bound round with slender strips of cane. In both these forms, it is of a dark reddish-brown colour, opaque, and readily pulverizable, affording a fine scarlet powder. It sometimes comes also in the form of a reddish powder, and in small irregular fragments or tears. An inferior kind, said to be obtained by boiling the fruit in water, is in *flat circular cakes*, two or three inches in diameter and half an inch thick. This also yields a fine red powder. A fourth variety, much inferior even to the last mentioned, is in *large disks*, from six to twelve inches in diameter, by an inch in thickness, mixed with various impurities, as pieces of the shell, stem, &c., and supposed to be derived from the fruit by decoction with expression. A substance known by the name of dragon's blood is derived by exudation from the trunk of *Dracæna Draco*, a large tree inhabiting the Canary Islands and the East Indies, and another from *Pterocarpus Draco*, a tree of the West Indies and South America, by incision into the bark. These last, however, are little known in commerce. According to Lieut. Wellstead, much dragon's blood is obtained in the island of Socotra, by spontaneous exudation from a large tree, growing at a considerable elevation on the mountains.

Dragon's blood is inodorous and tasteless, insoluble in water, but soluble in alcohol, ether, and the volatile and fixed oils, with which it forms red solutions. According to Herberger, it consists of 90·7 parts of a red resin, which he calls *draconin*, 2·0 of fixed oil, 3·0 of benzoic acid, 1·6 of oxalate of lime, and 3·7 of phosphate of lime. It was formerly employed in medicine as an astringent, but is nearly or quite inert, and is now never given internally. It is sometimes used to impart colour to plasters, but is valued chiefly as an ingredient of paints and varnishes. W.

DUTCH PINK. A yellow or brownish-yellow paint, consisting of clay, or a mixture of clay and chalk, or carbonate of lime in the form of whiting, coloured by a decoction of woad, French berries, or birch leaves, with alum. W.

EMERY. A very hard mineral, the powder of which is capable of wearing down all other substances except the diamond. As existing in commerce, it is said to be derived chiefly from the island of Naxos, in the Grecian Archipelago; but, according to Landerer, it has been found also in Asia Minor and the Morea. Within a few years a new locality of emery has been discovered at Chester, Hampden County, Mass., where a vein of this valuable mineral exists, of an average width of four feet, and several miles in length. For details in reference to this subject, the reader is referred to a paper by Prof. J. Lawrence Smith, in the *American Journal of Sciences and Arts* (A. D. 1866, 2d ser., xlii. 83). Emery is pulverized by grinding it in a steel mill, and the powder is kept in the shops of different degrees of fineness. It is used for polishing metals and hard stones. The method, adopted in Smyrna, of ascertaining its purity, is to rub a plate of glass of known weight with a certain quantity of the suspected mineral until it ceases to have any effect. The loss of weight in the glass is the measure of the value of the emery. (See *Am. Journ. of Pharm.*, March, 1862, p. 187.) W.

EPIGÆA REPENS. *Trailing Arbutus. Ground Laurel. May-flower.* This is a small trailing plant, with woody stems from six to eighteen inches long, entire, cordate-ovate leaves, and small, very fragrant flowers, which appear early in the spring. It is found in the woods, and affects the sides of hills with a northern exposure. Dr. Darlington states that the plant has been supposed to be injurious to cattle, when eaten by them. (*Flora Cestrica*, p. 259.) The late Dr. Eli Ives, of New Haven, Connecticut, furnished us with the following account of its virtues and uses, founded on his own observation. "The Epigæa repens has been freely used for some years in diseases of the urinary organs, and of the pelvic viscera generally, particularly of irritated action, in those cases in which the uva ursi and buchu are indicated. The leaves and stems are prepared in the same manner, and administered in the same dose as the uva ursi. The Epigæa has given relief in some cases where the uva ursi and buchu have failed. May 4th, 1849." W.

EPILOBIUM ANGUSTIFOLIUM. (*Gray's Manual*, p. 130.) *Willow-herb.* There are several species of Epilobium, which have the common name of willow-herb from the resemblance of their leaves to the willow, and probably have nearly identical properties. They are all perennial and indigenous. The E. angustifolium is the largest of them, having a simple stem, from four to seven feet high. It is common in the Northern States, frequenting low, or newly-cleared grounds. It bears showy purple flowers, which appear in July and August. The leaves and roots are said to be demulcent, tonic, and astringent, and yield their virtues to water and alcohol. They are used by the "eclectics," generally and locally, in decoction, infusion, or cataplasm, in cases which call for the use of astringent remedies. W.

EQUISETUM HYEMALE. (*Gray's Manual*, p. 585.) *Horsetail. Scouring Rush.* An indigenous cryptogamous plant, with slender annual stems from a foot and a half to three feet high, growing abundantly in the Northern States, and preferring wet places, as the banks of streams, &c. The plant derives its name of scouring rush from its use in scouring, for which it is fitted by the siliceous character of the stems. It has the reputation of being diuretic, and is used sometimes in dropsical diseases and those of the urinary passages. The whole plant is employed, usually in the form of infusion. W.

ERECHTHITES HIERACIFOLIA. (*Gray's Manual*, p. 230.) *Fireweed.* An annual indigenous plant, growing in moist woods and recent clearings, and having a rank odour, though somewhat aromatic, which probably called attention to the plant in reference to its use in medicine. Its taste is bitterish, slightly acrid, and disagreeable. It yields these and what medical virtues it may possess to water. It has been especially recommended in dysentery. This plant is apt to infest the peppermint fields of Michigan; and its oil is said sometimes to deteriorate the oil of peppermint from that region. W.

ERODIUM CICUTARIUM. *Storksbill.* (*Gray's Manual*, p. 73.) An annual hairy plant, with spreading stems, pinnate leaves, and several-flowered peduncles, belonging to the family of *Balsaminaceæ*, and growing in the northern parts of this country, especially on the banks of Oneida Lake, New York. It is highly recommended by Dr. W. Abbotts Smith in the treatment of dropsy. He uses it in the form of decoction, made by boiling two ounces of the dried bark with three pints of water down to two, then decanting and straining. (See *Am. Journ. of Med. Sci.*, Jan. 1865, p. 240.) W.

ERYNGIUM AQUATICUM. *Button Snakeroot.* The root of Eryngium aquaticum was recognised as officinal in the Secondary Catalogue of the U. S. Pharmacopœia, until the recent revision, when it was dismissed. The plant belongs to Pentandria Digynia of the Linnæan system, and to the natural order Apiaceæ or Umbelliferæ. The following is its generic character. "*Flowers* capitate. *Involucrum* many-leaved. Proper *calyx* five-parted, superior, persistent. *Corolla* of five petals. *Receptacle* foliaceous, segments acute or cuspidate. *Fruit* bipartite." (*Nuttall.*) The *button snakeroot* or *water eryngo* is an indigenous herbaceous plant, with a perennial tuberous root, and a stem two or three feet

high, sometimes, according to Pursh, six feet, generally branching by forks, but trichotomous above. The leaves are very long, linear-lanceolate on the upper part of the stem, sword-shaped below, with bristly spines at distant intervals upon their margin. The floral leaves are lanceolate and dentate. The flowers are white or pale, and in globose heads, with the leaflets of the involucrum shorter than the head, and, like the scales of the receptacle, entire. This plant is found in low wet places, as far south as Virginia and N Carolina. Its period of flowering is August. The root, which is the medicinal portion, has a bitter, pungent, aromatic taste, provoking, when chewed, a flow of saliva. It is diaphoretic, expectorant, in large doses occasionally emetic; and has been used by some physicians in decoction as a substitute for seneka. (*Bigelow.*) We are told in Barton's *Collections*, that it is nearly allied to the contrayerva of the shops. W.

ERYTHRONIUM AMERICANUM. (Muhl. *Catalogue*, 84; Bigelow, *Am. Med. Bot.*, iii. 151.)—*E. lanceolatum.* (Pursh, p. 320.) The root and herb of this plant were officinal in the U. S. Pharmacopœia, in which they occupied a place in the Secondary Catalogue until the late revision. The plant belongs to Hexandria Monogynia in the Linnæan system, and to the natural order of Liliaceæ. The following is the generic character. "*Calyx* none. *Corolla* inferior, six-petaled; the three inner petals with a callous prominence on each edge near the base." (*Bigelow.*) This is an indigenous perennial bulbous plant, sometimes called, after the European species, *dog's tooth violet.* The bulb (cormus), which is brown externally, white and solid within, sends up a single naked slender flower-stem, and two smooth lanceolate, nearly equal leaves, sheathing at their base, with an obtuse callous point, and of a brownish-green colour diversified by numerous irregular spots. The flower is solitary, nodding, yellow, with oblong-lanceolate petals obtuse at the point, a club-shaped undivided style, and a three-lobed stigma. The Erythronium grows in woods and other shady places throughout the Northern and Middle States. It flowers in the latter part of April or early in May. All parts of it are active. In the dose of twenty or thirty grains, the recent bulb operates as an emetic. The leaves are said to be more powerful. The activity of the plant is diminished by drying. W.

ERYTHROXYLON COCA (Lamarck). *Coca.* This is a shrub growing wild in South America, and largely cultivated in Bolivia for the sake of its leaves, which are much used in that country as a masticatory. The plant, which is propagated from the seed in nurseries, begins to yield in eighteen months, and continues productive for half a century. The leaves, on being picked, are dried in the sun, and then packed in bags. They are known in South America by the name of *coca.* They were in general use among the natives of Peru at the time of the conquest, and have continued to be much employed to the present time.

The leaves resemble in size and shape those of tea, being oval-oblong, pointed, two inches or more in length by somewhat over an inch in their greatest breadth, and furnished with short delicate footstalks; but they are not, like the tea-leaves, dentate, and are distinguished from most other leaves by a slightly curved line on each side of the midrib, running from the base to the apex. When well dried, they have an agreeable odour resembling that of tea, and a peculiar taste, which, in decoction, becomes bitter and astringent. Some attempts were made to analyze coca before the publication of the eleventh edition of this Dispensatory, of which the main result was, that the leaves contained a peculiar very bitter principle on which their virtues probably depended. M. Stanislas Martin afterwards made a hasty examination, from which it appeared that they contain a peculiar bitter principle, resin, tannin, an aromatic principle, extractive, chlorophyll, a substance analogous to thein, and salts of lime. (*Journ. de Pharm.*, Avril, 1859, p. 283.) Dr. Albert Niemann, of Goslar, has made a more thorough investigation of the leaves, and succeeded in isolating a peculiar alkaloid, to which he gives the name of *cocaina.* The following was his process. The leaves were exhausted with 85 per cent. alcohol acidulated with 2 per cent. of sulphuric acid; the tincture was treated with milk of lime and filtered; the filtrate was neutralized with sulphuric acid, and the alcohol distilled off. The syrupy residue was treated with water to separate resin, and then precipitated by carbonate of soda. The deposited matter was exhausted by ether, and the ethereal solution, after most of the ether had been distilled, was allowed to evaporate spontaneously. The cocaina was thus obtained in colourless crystals, mixed with a yellowish-brown matter of a disagreeable odour, which was separated by washing with cold alcohol. Pure cocaina is in colourless transparent prisms, inodorous, of a bitterish taste, soluble in 704 parts of cold water, more soluble in alcohol, and freely so in ether. The solution has an alkaline reaction, and a bitterish taste, leaving a peculiar numbness on the tongue, followed by a sensation of cold. The alkaloid melts at 208° F., and on cooling congeals into a transparent mass, which gradually becomes crystalline. Heated above this point it changes colour, and is decomposed. It is inflammable, burning with a bright flame, and leaving charcoal. With the acids it forms soluble and crystallizable salts, which are more bitter than the alkaloid itself. It was found to consist of carbon, hydrogen, nitrogen, and oxygen; and the formula as given by Dr. Niemann is $C_{32}H_{20}NO_3$. He also obtained wax, a variety of tannic acid (*cocatannic acid*), and a concrete volatile

odorous substance. (See *Am. Journ. of Pharm.*, March, 1861, p. 122.) Mr. Maisch, of Philadelphia, succeeded in obtaining from the leaves an uncrystallizable alkaloid, having so nearly the properties of cocaina that he considered it merely as the result of the action of heat on the crystallizable principle. (*Ibid.*, Nov. 1861, p. 500.) Still more recently M. Lossen has examined cocaina, and ascertained that, when heated with muriatic acid, it splits into benzoic acid and a new base which he calls *ecgonin*. The mutability of cocaina with acids, explains why the attempts to extract the alkaloid with acid liquids have failed. M. Lossen therefore recommends the omission of acid in operating on the leaves, and proposes the following modification of Niemann's plan. An infusion is first made; this is precipitated with acetate of lead; the lead is removed by sulphate of soda; the liquid is concentrated, carbonate of soda added, and the whole shaken with ether. The ether extracts the alkaloid, and yields it in a crude state by evaporation. It is then purified as in the process of Dr. Niemann. (*Journ. de Pharm.*, Juin, 1862, p. 522.)

According to Dr. Weddell, coca produces a gently excitant effect, with an indisposition to sleep; in these respects resembling tea and coffee. It is asserted to support the strength for a considerable time in the absence of food; but it does not supply the place of nutriment, and probably, in this respect also, acts like the two substances referred to. The Indians, while chewing it, pass whole days in travelling or working without food; but they nevertheless eat freely in the evenings. Weddell states that persons, unused to it, are liable to unpleasant effects from its abuse; and he has known instances of hallucinations apparently resulting from this cause. The natives chew with it some alkaline substance, as the ashes of certain plants, or lime. (Weddell, *Voyage dans le Nord de la Bolivia.*) In large quantities, it is said to produce a general excitation of the circulatory and nervous systems, imparting increased vigour to the muscles as well as to the intellect, with an indescribable feeling of satisfaction, amounting altogether sometimes to a species of delirium; and, what is most singular, if true, this state of exaltation is asserted not to be followed by any feelings of languor or depression. (Mantegazza, *N. Am. Med.-chir. Rev.*, March, 1860, p. 340.) A medium dose is from three to four drachms, taken in infusion. For the result of experiments on the physiological action of coca by M. Reis, see *Ann. de Thérap.* (1864, p. 118). From experiments by MM. Gorse and Mantegazza, it is inferred that it increases the frequency of the heart's contractions considerably more than tea or coffee; and, in doses of about an ounce, it causes intense fever, attended with hallucinations and delirium. (Dr. Reis, *Pharm. Journ.*, 2d ser., viii. 299; from *Bullet Gén. de Thérap.*, Fev. 28, 1866.) M. Moreno, in experiments on animals with coca, found that, so far from supplying the place of food, it causes a more speedy death and a greater loss of weight than starvation alone. (*Ann. de Thérap.*, 1869, p. 64.) Coca has been employed, with supposed advantage, in connection with ergot, in obstinate cases of paraplegia, by Dr. Verardini, of Bologna. (*N. Y. Med. Journ.*, Nov. 1867, p. 160.) A European apothecary, at La Paz, Bolivia, uses the sulphate of cocaina as a substitute for sulphate of quinia in intermittents. (Fuentès, *Journ. de Pharm.*, 4e sér., iv. 268.) W.

ESSENCE OF BEEF. *Essence of Mutton.* Under the names of *essence of beef*, *essence of mutton*, &c., a preparation has been long in use, consisting of a saturated solution, at a boiling temperature, of the soluble principles of the meat employed in its own juice. Beef being the kind of meat generally preferred, the *essence of beef* is the preparation which has been most used, though the *essence of mutton* might be substituted in cases in which its flavour would be more acceptable. These preparations are made in the following manner. The flesh, having been deprived as far as possible of fatty matter, and cut into very small pieces, is introduced without water into a convenient long-necked bottle (a common quart porter bottle will answer the purpose very well) until this is filled; the bottle is then placed upright in a pot of boiling water, so that the top of the bottle shall be above the surface of the liquid, and is exposed to a boiling heat for an hour or more; the mouth of the bottle being closed with a cork so tightly as to prevent the escape of vapour, but not so as to endanger the breaking of the vessel. At the end of the process, the liquid is to be poured out of the bottle, and when sufficiently cool, is ready for use. It is highly nutritive, and at the same time stimulant, and may often be used with great advantage in the prostrate conditions of low fevers, when the stomach is quite free from inflammation. We have known serious mischief to arise from a neglect of this precaution. The dose is from a teaspoonful to a tablespoonful, which may be repeated every hour or two, in alternation with stimulant medicines. W.

EUCALYPTUS GLOBOSUS. A tree of considerable size growing in Australia, belonging to the order *Myrtaceæ*. Its wood is hard, and used in ship-building. By Dr. Ullersperger, of Munich, it is stated that the leaves, given in infusion, have been used with the "greatest success" in fevers; and a case of intermittent was cured by them in which quinia had failed. Unlike the last-mentioned remedy, this may be given during the febrile paroxysm, and ameliorates instead of aggravating it. Dr. Salarich, in the "*Espanna Medica*," recommends it also in nervous headache. (*B. and F. Med.-chir. Rev.*, Jan. 1868, p. 250; from *Schmidt's Jahrbücher*, &c., Dec. 10, 1866.) W.

EUPHORBIUM. This was contained in the Materia Medica Catalogue of the late Edinburgh Pharmacopœia; but, having been omitted in the British, it is no longer offi-

cinal. It is the concrete resinous juice of one or more species of Euphorbia, but its precise source is uncertain. It has been ascribed to *E. officinarum*, growing in the North of Africa and at the Cape of Good Hope, *E. Canariensis*, a native of the Canary Islands and Western Africa, and *E. antiquorum*, inhabiting Egypt, Arabia, and the East Indies, and supposed to be the plant from which the ancients derived this resinous product. These species of Euphorbia bear some resemblance in form to the *Cactus*, having leafless, jointed, angular stems, divided into branches of a similar structure, and furnished with double prickles at the angles. When wounded they yield an acrid milky juice, which concretes on the surface, and, being removed, constitutes the euphorbium of commerce.

This occurs in the shape of tears, or in oblong or roundish masses, about the size of a pea or larger, often forked, and perforated with one or two small conical holes, produced by the prickles of the plant, around which the juice has concreted, and which sometimes remain in the holes. The masses are occasionally large and mixed with impurities. The surface is dull and smooth, bearing some resemblance to that of tragacanth; the consistence somewhat friable; the colour light yellowish or reddish; the odour scarcely perceptible; the taste at first slight, but afterwards excessively acrid and burning. The colour of the powder is yellowish. The sp. gr. of euphorbium is 1·124. Triturated with water it renders the liquid milky, and is partially dissolved. Alcohol dissolves a larger portion, forming a yellowish tincture, which becomes milky on the addition of water. Its constituents, according to Pelletier, are resin, wax, malate of lime, malate of potassa, ligain, bassorin, volatile oil, and water. Brandes found caoutchouc. It contains no soluble gum. The proportions of the ingredients are variously stated by different chemists, and probably vary in different specimens. The most abundant is resin, and the remainder consists chiefly of wax and malate of lime. The resin is excessively acrid, is soluble in alcohol, and when exposed to heat, melts, takes fire, and burns with a brilliant flame, diffusing an agreeable odour. Dr. Flückiger has found a substance analogous to lactucon which he names *euphorbon*. It is neuter, fusible above 228° F., readily dissolved by boiling alcohol, and soluble in ether, benzine, amylic alcohol, chloroform, acetone, and glacial acetic acid. From its solution in ether and benzine, it separates, on spontaneous evaporation, in feathery needles. Its solution in sulphuric acid, spread on a plate, is coloured violet by nitric acid. Its composition is $C_{26}H_{22}O_2$. While the acrid resin constitutes 38 per cent. of euphorbium, euphorbon constitutes 22 per cent. (*Am. Journ. of Pharm.*, Sept. 1868, p. 393; from *Schweizerische Wochenschrift.*)

Medical Properties and Uses. Euphorbium taken internally is emetic and cathartic, often acting with great violence, and in large doses producing severe gastric pain, excessive heat in the throat, and symptoms of great prostration. In consequence of the severity of its action, its internal use has been entirely abandoned. Applied to the mucous membrane of the nostrils, it excites violent irritation, attended with incessant sneezing and sometimes bloody discharges. They who powder it are under the necessity of guarding their eyes, nostrils, and mouth against the fine dust which rises. Largely diluted with wheat flour or starch, it may be used as an errhine in amaurosis, deafness, and other obstinate affections of the head. Externally applied it inflames the skin, often producing vesication; and on the continent of Europe is sometimes used as an ingredient of epispastic preparations. It is employed in veterinary practice, with a view to its vesicating power. W.

EUPHRASIA OFFICINALIS. *Eyebright.* A small annual plant, common to Europe and the United States, without odour, and of a bitterish, astringent taste. It was formerly used in various complaints, and among the rest in disorders of the eyes, in which it was thought to be very efficacious, and in the treatment of which it is still popular in some countries. The probability is that it is nearly inert. W.

EXTRACTUM CARNIS. Liebig. *Extract of Flesh. Extract of Meat.* The nature of this preparation is truly expressed by its name. Its object is to obtain the nutritive matters of the flesh of animals in a concentrated state, in which they may be long kept without change. Two great advantages are thus gained, cheapness of carriage, and the facility of transfer from places, however remote, where meat is plentiful, to others where it is most needed. Thus, the cattle so abundant on the plains of South America, Australia, and Russia, may be made to contribute to the support of the people of Europe and North America; and this object has already been in some degree accomplished; as factories are in operation in these regions by which, in the condition of *extract of flesh*, beef is largely prepared for distribution over the world; and South American extract of beef is well known in the markets of London, and other European capitals. Though to Liebig belongs the credit of setting this movement on foot, and his process is probably most extensively used, others have employed processes of their own, and some are perhaps equal if not superior to his. To a paper by M. Poggiale, in the *Journal de Pharmacie* (Mars, 1868, p. 172), we must express our indebtedness for many of the facts contained in the present article.

Liebig's extract of beef, besides what is made by various independent operators, who, employing his process, take advantage of the popularity of his name in spreading their products abroad, is now largely prepared by a company which, under his supervision, has established itself in South America. According to M. Poggiale, the process there in use consists in preparing a broth with equal parts of the meat cut fine and of cold water, straining this through a linen cloth, evaporating it in a boiler over a naked fire till

reduced to one-sixth of its volume, and then at a lower temperature, by means of a vacuum apparatus, bringing it to the consistence of an extract. The extract thus made is introduced in varnished stoneware jars, which are carefully closed to exclude the air. It is said that 100 parts of meat yield 2·5 of extract. The preparation keeps well, contains neither fat nor gelatin, and is rich in the nitrogenous principles. It is of a reddish-brown colour, a slightly acrid taste, and an odour that is not agreeable; so that when dissolved in hot water to make soup, it is necessary, in order to make a savory dish, to add leguminous fruits to the extract. To avoid this flavour it would be necessary to effect the evaporation out of contact with the air, and if possible altogether in a vacuum.

The following more particular account of the S. American establishment is given by Mr. Hutchinson, in his "*Parana and South American Recollections*," recently published. The works are situated at Fray Bentos, and would appear, from a statement in the *Buenos Ayres Standard* (Sept. 3, 1868), to be of very great extent, covering 20,000 square feet, and "working off" 400 oxen daily. There are four processes in the manufacture; 1. chopping the flesh into mincemeat; 2. the digestive process, in which the chopped meat is exposed to steam in vast iron digesters, each holding 12,000 lbs.; 3. the separation, by straining through wire gauze and clarification, of the fat, albumen, and fibrin; and 4. evaporation, which is wonderfully accelerated by the rotatory motion of thin, circular, steel plates, by means of which more than two millions of square feet of a thin layer of the liquid are exposed to the air in one minute. Liebig directs that, in the preparation of beef-tea, 1 part of the extract should be employed to 100 of water; but the nutritive matter in the extract is said to vary greatly; and Dr. Letheby, in specimens examined by him, found 45 per cent. of water; so that the proportion fixed by Liebig must be greatly increased in reference to inferior specimens. The varying quality of the extract is ascribed, in part at least, to the character of the meat; that from grown animals differing from that of young, and of the male from the female; while, altogether, the mode of living of the roving cattle of the plains would be likely to lead to inferior results. (*Med. Times and Gaz.*, Jan. 1869, p. 92.) In a letter from Baron Liebig to the *Pharm. Journ.* for Nov. 1866, it is stated that the meat of oxen always yields an extract darker and more strongly flavoured, resembling somewhat the flavour of fresh venison, pleasant when diluted; that of cows' meat lighter-coloured, and of a mild flavour; while that of young animals, under four years, is unfit for the preparation of extract, which from such a source is pappy, of a feeble taste like veal, and without flavour. (*Am. Journ. of Pharm.*, March, 1867, p. 145.)

In preparing his extract, M. Bellat exhausts the meat, deprived of fatty matter and tendinous and membranous tissues, and very finely divided, with cold water by the process of percolation, and setting aside the infusion thus obtained, puts the residuary matter into vats heated by vapour and hermetically closed by strong covers; adds an equal weight of water, and a small quantity of bones; digests for six hours at about 200° F., agitating occasionally; then submits the material to the action of an hydraulic press, adds a suitable proportion of water and legumes, and boils the whole. The liquids prepared with heat and without it are now mixed, heated in boilers so as to coagulate any blood present, and, having been rapidly filtered, are evaporated in a vacuum apparatus to the consistence of very thick honey. Thus made, the extract is finally introduced into tin cans, and closed after the manner of Appert. This extract is of a yellowish-brown colour, rather soft, very soluble in water, and possessed of the smell and taste of fresh soup. By adding 25 *grammes* of it to a *litre* of boiling water, with sufficient salt, M. Poggiale obtained a soup having all the characters of that recently made from fresh meat. (*Journ. de Pharm.*, Mars, 1868, p. 172.)

M. Martin de Lignac prepares the extract by boiling 100 kilogrammes of beef (flesh and bones), 20 of fresh pulse, 5 of knuckles of veal, and 100 grammes of common salt, all well divided, in one and a half times their weight of water, and, when the soup is prepared, allowing it to rest, decanting, filtering, and lastly evaporating, by means of a water-bath, at about 160° F., down to 10° of Baumé. The extract is then put into metallic boxes, and preserved by the method of Appert. It is in the form of a translucent jelly, of sufficient firmness, which it owes to the gelatin of the bones. It has a very agreeable smell and taste, and, dissolved in boiling water, yields an excellent soup. This is said to be much used in Paris. (*Journ. de Pharm.*, Mars, 1868, p. 173.)

M. F. J. Tourtelot gives the following formula of an extract prepared by him, which has been for seven years employed in the U. S. Army, and in private practice in this country. His process is based on the propriety of preserving the albumen in the extract, which is undoubtedly beneficial so far as its nutrient qualities are concerned. The fresh beef, deprived of bone, fat, and sinew, and finely chopped, is macerated with cold water for about two hours; steam is then introduced into the vats until the temperature rises to 120° F., care being taken to stir the meat frequently; and the resulting liquid, which contains the albumen, is drawn off, strained, and set aside. The residue is boiled with water for some hours, the liquor separated by gentle pressure, and immediately transferred to the vacuum pan, where it is reduced to one-fourth, when the liquid first obtained is added; after which the evaporation is continued until one pound of the extract represents 20 lbs. of meat. It is then poured into china jars, and covered with waxed paper, coated with tincture of Tolu. (See *Am. J. of Pharm.*, March, 1869, p. 158.) This preparation appears to be based on correct principles.

The extract of meat has all the advantage as an article of diet of common soups, but by no means represents the nutritive qualities of the meat itself; as the two most nutritious ingredients of flesh, albumen and fibrin, are in general wholly wanting; and efforts are made as far as possible to get rid of fat, and in most instances of gelatin also, though, in relation to the latter principle, with, in our opinion, questionable propriety. There can be no doubt, however, that it is nutritious; and for the sick, especially in low fevers, it is recommended by possessing in addition the somewhat stimulant properties characteristic of the meat essences. For an account of the chemical constitution of extract of flesh, by Messrs. H. Deane and H. B. Brady, for which we have no space here, the reader is referred to the *Pharmaceutical Journal* (Oct. 1866, p. 199). W.

FERRIDCYANIDE OF POTASSIUM. *Red Prussiate of Potassa.* This is formed by passing a current of chlorine through a solution of ferrocyanide of potassium, until the liquid ceases to form a precipitate with a solution of sesquichloride of iron, a proof that the whole of the ferrocyanide has been converted into the ferridcyanide. The solution, by due evaporation, yields the compound in question. It may also be prepared, in the dry way, by agitating chlorine with the finely powdered ferrocyanide, as long as it is absorbed. The theory of the formation of this compound is that one eq. of chlorine withdraws from two eqs. of the ferrocyanide, one eq. of potassium, forming chloride of potassium which remains in the mother-water. The reaction is explained by the following equation: 2 (K_2Cfy) and $Cl{=}K_3Cfy_2$ and KCl. The radical ferridcyanogen is supposed to be formed by the coalescence of two eqs. of ferrocyanogen, and is represented by the symbol Cfdy. Accordingly, the formula of ferridcyanide of potassium is K_3Cfdy. This salt, discovered by Gmelin, is in beautiful deep hyacinth-red anhydrous crystals, which are soluble in four parts of water. Its solution forms a delicate test of the salts of protoxide of iron, with which it produces a blue precipitate; but with the salts of the sesquioxide, it only strikes a green or brown colour. Ferridcyanide of potassium is directed by the U. S. Pharmacopœia, in conjunction with sulphate of protoxide of iron, as a test of the chlorine strength of chlorinated lime. (See *pages* 195–6.) It is used in dyeing and calico-printing. B.

FERROCYANIDE OF ZINC. *Zinci Ferrocyanidum. Ferrocyanuret of Zinc.* Formed by double decomposition between hot solutions of ferrocyanide of potassium (ferroprussiate of potassa) and sulphate of zinc. It is thrown down as a white powder. It has similar medical properties to those of the cyanide, and is used in the same diseases. The dose is from one to four grains, given in pill. (See *Cyanide of Zinc.*) B.

FLAVOURING EXTRACTS. Under this name, preparations from various aromatics are considerably used for culinary purposes. They are in the liquid form, and are generally alcoholic solutions of the sapid and odorous principles of substances having an agreeable flavour, such as lemon and orange peel, bitter almonds, roses, cinnamon, mace, ginger, and celery. Formulas for their preparation, given by Prof. Procter, may be found in the *Am. Journ. of Pharm.* for May, 1856, p. 215. Others have been added to the list, in a recent communication by Prof. Procter to the same journal (July, 1866, p. 294). The new formulas are for extracts of nutmeg, of soup herbs (thyme, sweet marjoram, sweet basil, summer savory, and celery seed), coriander, and vanilla. W.

FORMIATE OF AMMONIA. From the fact that formiate of ammonia is a chemical homologue of acetate of ammonia, the acid of the former being a derivative of methyl, as acetic acid is of ethyl, it has been suggested that they might resemble each other in their medicinal relations; but, though formic acid is irritant to the skin like the acetic, it has not proved, upon trial, that the two salts have any strong resemblance. The formiate of ammonia has been employed by Dr. Ramskill, at the Hospital for the Epileptic and Paralytic, in London, who considers it useful in chronic paralytic disease with general torpor; especially in cases of reflex paralysis, and, in a less degree, in the paralytic condition arising from long disuse of the muscles. It is said to be equally applicable to palsy of sensation and motion. It is contraindicated by any remaining active irritation or inflammation of the nervous centres or about them, which may have been the original seat of the lesion. The inference is that formiate of ammonia is a stimulant with a special tendency to the nervous centres, and probably analogous to the carbonate. The dose is five grains; and a larger quantity than this is apt to vomit. Patients experience a glow in the region of the stomach when they swallow it. *Formic acid*, diluted with an equal measure of water, is said to be an excellent application to paralyzed limbs, exciting the circulation, and producing erythematous redness, with a prickling sensation as if stung with nettles. (*N. Y. Med. Journ.*, April, 1865, p. 80; from *Med. Times and Gaz.*) W.

FRAXINUS EXCELSIOR. *Common European Ash.* It has been stated, in the first part of this work, that, in the South of Europe, this tree yields manna by incisions in its trunk. In this place, however, it is noticed only in reference to its bark and leaves. The bark is bitter and astringent, and, before the introduction of cinchona into use, was employed in the treatment of intermittent fever; but has since fallen into neglect. Keller believed that he had found in the bark a peculiar crystallizable organic alkali, which Buchner denominated *fraxinin;* but Rochleder and Schwartz have since shown that the crystals, formed along with the bitter substance obtained by the process of Keller, were nothing but mannite. (*Pharm. Cent. Blatt*, May, 1853, p. 312.) Since that period, however, a crystal-

lizable bitter principle has been discovered by Prince Salm-Horstman, which has been named *fraxinin*. It is obtained by precipitating the decoction with acetate of lead, washing the precipitate, decomposing it by sulphuretted hydrogen, and concentrating the solution, which deposits the fraxinin in needle-shaped crystals. These are four-sided prisms, shining, white with a tinge of yellow, feebly bitter and astringent, inodorous, soluble with difficulty in cold but readily in hot water. The concentrated warm solution has an acid reaction. When much diluted, it exhibits a clear blue fluorescence by daylight, especially if a trace of ammonia is present. Alkalies, alkaline earths, and the carbonates colour it yellow; and chloride of iron first colours it green, and then throws down a yellow precipitate. (*Chem. Cent. Blatt*, July 8, 1857, p. 452.) The *leaves* have been at different times recommended as an antidote to the poison of serpents, and as a remedy in scrofula. Within a few years they have been introduced into use in Germany in the treatment of gout and rheumatism, in which they have acquired considerable reputation. Drs. Pouget and Peyraud, of France, have spoken in the highest terms of their efficacy in these diseases; and, upon the authority of the former, it is stated that they have been used for forty years by the peasants of Auvergne as a specific in gout. M. Garot has shown that they contain 16 per cent. of *malate of lime*, to which it is thought their anti-arthritic virtues may be ascribed. (*Journ. de Pharm.*, 3e sér., xxiv. 311.) The leaves have been said to be purgative; but this is contradicted by Drs. Pouget and Peyraud. An ounce may be infused in half a pint of boiling water, and taken three times a day. (See *Am. Journ. of Med. Sci.*, N. S., xxv. 492.) W.

FRENCH CHALK. A variety of indurated talc. It is compact, unctuous to the touch, of a greenish colour, glossy, somewhat translucent, soft and easily scratched, and leaves a silvery line when drawn over paper. It is used chiefly for marking cloth, &c., and for extracting grease spots. W.

FRUIT ESSENCES, ARTIFICIAL. Several of the compound ethers have been found to possess the odour and flavour of certain fruits, a property which has led to their employment as flavouring materials for confectionery and desserts, under the name of fruit essences. The simple ethers, present in these compounds, so far as they have become of commercial importance, are common ether or oxide of ethyl, which should be called ethylic ether, and oxide of amyl or amylic ether. Each of these ethers possesses basic properties, and has its alcohol; common or ethylic ether corresponding to common or ethylic alcohol, and amylic ether to amylic alcohol or fusel oil. These alcohols are hydrated oxides of ethyl and amyl respectively. (See *Alcohol Amylicum*, p. 85, and *Alcohol*, p. 77.)

Butyrate of Ethylic Ether. Butyric Ether. ($C_4H_5O,C_8H_7O_3$.) This ether is readily prepared by mixing 100 parts of butyric acid with 100 of alcohol, and 50 of concentrated sulphuric acid, and agitating the mixture for a short time. The ether forms a layer on the surface, and may be purified by washing it with water, and subjecting it to the action of chloride of calcium. Butyric ether is sparingly soluble in water, but very soluble in alcohol, and boils at 230°. It is said to be much used to communicate a pine-apple flavour to rum. Dissolved in 8 or 10 parts of alcohol it forms the *pine-apple essence*. From 20 to 25 drops of this essence, added to a pound of sugar containing a little citric acid, imparts to the mixture a strong taste of pine-apple. *Butyric acid* is formed during what is called the butyric fermentation, which usually consumes two or three months before it is completed, and which is preceded by the lactic fermentation. To prepare it a solution of grape sugar is mixed with half its weight of chalk, and with about one-tenth of its weight of cheese to act as a ferment, and the whole is kept at the temperature of 90°. The sugar is first transformed into a viscous substance, and afterwards into lactic acid, which is gradually converted into butyric acid, with the disengagement of hydrogen and carbonic acid. At the end of the fermentation, the liquid contains principally a mixture of butyrate and lactate of lime, from which the butyric acid may be obtained by precipitating the lime as a carbonate by carbonate of soda, and decomposing the resulting butyrate of soda with sulphuric acid. Butyric acid is a colourless liquid, having a very disagreeable odour and a rancid taste. It dissolves in all proportions in water and alcohol, boils at 327°, and has the density 0·963. It is a hydrated acid, having the formula $C_8H_7O_3,HO$.

Pelargonate of Ethylic Ether. Pelargonic Ether. Œnanthic Ether. ($C_4H_5O,C_{18}H_{17}O_3$.) A preliminary step in forming this ether is to prepare the *pelargonic acid*. This is most conveniently obtained, according to Dr. R. Wagner, by the action of nitric acid on oil of rue. Treat the oil with double its weight of very dilute nitric acid, and heat the mixture until it begins to boil. Two layers are formed in the liquid; the upper one being brownish, and the lower consisting of the products of the oxidation of the oil, with the excess of nitric acid. The lower layer, having been separated, is freed from the greater part of the nitric acid by evaporation in a chloride of zinc bath, and then filtered. The filtrate is a solution of pelargonic acid, and may be converted into pelargonic ether by a prolonged digestion, at a gentle heat, with alcohol. The ether as thus prepared, has the agreeable odour of quince, and, when dissolved in alcohol in due proportion, forms the *quince essence*. (See *Am. Journ. of Pharm.*, July, 1853, p. 320.) *Pure* pelargonic ether (œnanthic ether) is a colourless liquid, having a peculiar, vinous, stupefying odour, and a taste, at first slight, but afterwards acrid. Its sp. gr. is 0·872, and boiling point, when constant, 433°. (*Delffs.*) It is insoluble in water, but dissolves readily in alcohol and ether. Pelargonic acid, first obtained from *Pelargonium roseum*, or rose geranium, is a hydrated acid, and has the form-

ula $C_{18}H_{17}O_3,HO$. Delffs's analysis of œnanthic acid gives it the same composition; and, accordingly, he considers the two acids as undoubtedly identical. (*Chem. Gaz.*, April 15 1852, p. 144.) Gregory adheres to the old formula for œnanthic acid, $C_{14}H_{13}O_3,HO$.

Acetate of Amylic Ether. ($C_{10}H_{11}O,C_4H_3O_3$.) This is prepared by distilling a mixture of one part of amylic alcohol (fusel oil), two of acetate of potassa, and one of concentrated sulphuric acid. The distilled liquid is purified from free acid by washing with a weak alkaline solution, and from water by distillation from chloride of calcium. It is a colourless, limpid liquid, lighter than water, boiling at 272°, insoluble in water, but soluble in alcohol. It possesses the odour, in a remarkable degree, of the Jargonelle pear, and is manufactured on a large scale for flavouring syrups and confectionery. An alcoholic solution of this ether forms the *Jargonelle pear essence.* Fifteen parts of acetate of amylic ether, with half a part of acetic ether, dissolved in 100 parts of alcohol, form what may be called the *bergamot pear essence*, which, when employed to flavour sugar acidulated with a little citric acid, imparts the odour of the bergamot pear, and a fruity, refreshing taste. Acetate of amylic ether, mixed with butyric ether, forms another fruity compound, which recalls the odour of the banana, and forms, in alcoholic solution, the *banana essence.*

Valerianate of Amylic Ether. ($C_{10}H_{11}O,C_{10}H_9O_3$.) This is made by carefully mixing four parts of pure amylic alcohol (fusel oil) with four of sulphuric acid, and adding the mixture, when cold, to five parts of valerianic acid. The whole is warmed for a few minutes in a water-bath, and then mixed with a little water, which causes the ether to separate. Lastly, it is purified by washing it with water and a weak solution of carbonate of soda. An alcoholic solution of this ether, in the proportion of one part to six or eight of alcohol, forms a flavouring liquid under the name of *apple essence.* For the mode of obtaining valerianic acid, see *Acidum Valerianicum* (page 981).

It is thus perceived that the bases of the fruit essences are certain ethereal compounds of organic acids with the oxides of ethyl and amyl. Besides the essences here described, there are found in commerce the strawberry, raspberry, apricot, greengage, mulberry, and black currant essences, all of which may be viewed as various mixtures of the ethers of the ethyl and amyl series, modified by the addition of pure nitrous ether, tincture of orris, vanilla, volatile oils, &c., to bring about a resemblance to the fruit, the odour and taste of which it is the object to imitate. In making these essences it is important that the materials should be pure, especially the fusel oil and alcohol. The alcohol, used as a solvent, should be rectified and deodorized.

These fruit essences are extensively employed for flavouring ices, jellies, lozenges, and drops, and for making fruit syrups and effervescent beverages. They are manufactured on a large scale by Messrs. Mander, Weaver & Co., of Wolverhampton, England; and the more useful ones are prepared by Messrs. Powers & Weightman, of Philadelphia. B.

M. Kletzinski has prepared a table giving the ingredients, and their proportions, of a large number of fruit essences, which we present below. He states that they are alcoholic solutions of different ethers, to which are sometimes added certain acid and natural essences. Glycerin is present in nearly all, being useful in blending and harmonizing the different odours. The alcohol and other ingredients must be chemically pure. Each column represents the number of measures to be added to 100 measures of alcohol.

Names of the Essences.	Chloroform.	Nitric Ether.	Aldehyde.	Acetate of Ethyl.	Formiate of Ethyl.	Butyrate of Ethyl.	Valerianate of Ethyl.	Benzoate of Ethyl.	Œnanthylate of Ethyl.	Essence of Persicot.	Sebacic Ether.	Salicylate of Methyl.	Amylic Alcohol.	Acetate of Amyl.	Butyrate of Amyl.	Valerianate of Amyl.	Essence of Lemon.	Essence of Orange.	Alcoholic Solutions saturated in the cold of: Tartaric Acid.	Oxalic Acid.	Succinic Acid.	Benzoic Acid.	Glycerin.

W.

FUCUS VESICULOSUS. *Sea-wrack. Bladder-wrack.* This was omitted as an officinal in the Dublin Pharmacopœia of 1850. It belongs to *Cryptogamia Algæ* in the sexual system, and to the natural order Algaceæ. The following is the generic character. "MALE. *Vesicles* smooth, hollow, with villose hairs within, interwoven. FEMALE. *Vesicles* smooth, filled with jelly, sprinkled with immersed grains, prominent at tip. Seeds solitary." This sea-weed is perennial, with the frond or leaf flat, smooth and glossy, from one to four feet long, from half an inch to an inch and a half broad, furnished with a midrib throughout its length, dichotomous, entire upon the margin, and of a dark olive-green colour. Small spherical vesicles, filled with air, are immersed in the frond near the midrib. The air in these vesicles has not the exact composition of atmospheric; consisting, according to the analysis of M. Ernest Baudrimont, in one instance of 28·4 per cent. of oxygen and 71·6 of nitrogen, in another 26·5 of the former and 73·5 of the latter. (*Journ. de Pharm.*, 4e sér., ii. 446.) The fruit consists of roundish, compressed receptacles, at the ends of the branches, filled with a clear tasteless mucus. The plant grows upon the shores of Europe and of this continent, attaching itself to the rocks by its expanded woody root. On the coasts of Scotland and France, it is much used in the preparation of kelp. It is also employed as a manure, and is mixed with the fodder of cattle. It has a peculiar odour, and a nauseous saline taste. Several chemists have undertaken its analysis, but the results are not satisfactory. It contains much soda in saline combination, and iodine, according to Gaultier de Claubry, in the state of iodide of potassium. These ingredients remain in its ashes, and in the charcoal resulting from its exposure to heat in close vessels. M. Eugene Marchand has ascertained that, though the ashes of the Fucus vesiculosus contain iodine, yet this species is one of those poorest in this constituent; and those of *Fucus digitatus* contain seven or eight times more. Consequently, if it be for the iodine that these plants are chiefly valuable, the latter is greatly preferable to the former. (*Journ. de Pharm.*, 4e sér., ii. 276.)

The charcoal, which is sometimes called *Æthiops vegetabilis* or *vegetable ethiops*, has long had the reputation of a deobstruent, and been given in goitre and scrofulous swellings. Its virtues were formerly ascribed chiefly to carbonate of soda, in which it abounds; but, since the discovery of the medical properties of iodine, this has been considered as its most active ingredient. The mucus contained in the vesicles was applied externally, with advantage, by Dr. Russell, as a resolvent in scrofulous tumours. M. Duchesne Duparc, having given a trial to this fucus in inveterate psoriasis, in which it had considerable reputation as a remedy, found it of little value; but he observed an unexpected effect, that of diminishing fat, without in other respects injuring the health; and was thus induced to try it as a remedy for morbid obesity. His anticipations of its efficacy in this affection were not disappointed. He employs the whole plant, either in substance in the form of pill, in decoction, or in extract. It is not till two or three weeks after beginning with the remedy that its effects in diminishing the obesity begin to be perceived, and one of the first signs of its favourable action in this respect is the increase of the urine, and the appearance of a black pellicle on its surface. Dr. Godsfrey tried the experiment on himself with satisfactory results, confirming the statements of M. Duchesne. (*Journ. de Pharm.*, Juillet, 1862, p. 65.) M. Dannecy prepares the extract from the plant, collected at the period of fructification about the end of June, in the neighbourhood of Bordeaux, and rapidly dried in the sun. This mode of desiccation is important, as, when dried by artificial heat, the plant never becomes friable, and always retains its hygroscopic qualities. When sufficiently dry to be friable, he treats it, in the state of coarse powder, for three days, with four times its weight of alcohol of 86°, expresses at the end of this time, and subjects the residue twice successively to a similar treatment with alcohol of 54°. The tinctures are then mixed, the alcohol distilled off, and the remainder evaporated to the consistence of an extract. Of this extract, which is one-fifteenth of the plant, three pills, each containing 25 centigrammes (3·75 grains), may be taken daily in the beginning, and increased gradually to twenty-four pills, a quantity which has often been attained without the slightest derangement of the stomach. The commencing dose would be about equivalent to twenty grains of the powder three times a day. (*Journ. de Pharm.*, Nov. 1862, p. 434.) A syrup may be readily prepared by dissolving the extract in a little diluted alcohol, and mixing this with syrup, in such proportion that a teaspoonful of the syrup shall contain a dose of the extract.

Other species of Fucus are in all probability possessed of similar properties. Many of them contain a gelatinous matter, and a sweet principle analogous to mannite; and some are used as food in times of scarcity. Large quantities of a sea-weed, named in the East *agar-agar*, are gathered on the rocky coasts of the East India Islands, and sent to China, where it is valued for making jellies, and as a size for stiffening silks. The *Ceylon moss* is a delicate fucus (*Gigartina lichenoides*), growing on the coast of Ceylon, where it is gathered by the natives. It abounds in starch and vegetable jelly, which render it applicable to the same purposes as the carrageen or Irish moss. (*Pharm. Journ.*, xiii. 355.) *F. Helminthocorton* (*Gigartina Helminthocorton* of Greville) has some reputation in Europe as an anthelmintic, and is said also to be febrifuge. It is an ingredient in the mixture of marine plants sold in Europe under the name of *Corsican moss* or *helminthocorton*. This is used in decoction, from four to six drachms being boiled in a pint of water, and a wineglassful given three times a day.

Attention has been called by Dr. Sloan, of Ayr, in Scotland, to the *Laminaria digitata*, commonly called *sea-girdles* or *tangles*, which grows about the shores of Scotland, as supplying an admirable material for bougies. The stem is from two to twelve feet long and an inch or more in breadth, is of great strength and tenacity, with the property of drying readily, and, in doing so, of shrinking much, and acquiring an elastic firmness, with a consistence, if the desiccation be arrested at the proper point, somewhat softer than horn. In this state the plant may be kept for years; and, if at any time exposed to moisture, will absorb it readily, and swell up to the original size. This last property renders it especially applicable for the formation of bougies to be used in the dilatation of strictures and sinuses, for which purpose it was recommended by Dr. Sloan, and has been found useful by others. Mr. M. H. Collis, of the Meath Hospital, Dublin, commends it highly, in a paper on the subject communicated to the *Dublin Quarterly Journ. of Med. Sci.* (May, 1864, p. 373), to which the reader is referred for further information on the subject. W.

FULIGOKALI. This preparation, proposed by M. Deschamps, is formed by boiling for an hour, 20 parts of caustic potassa, and 100 of shining soot, in powder, in a sufficient quantity of water. The solution, when cold, is diluted, filtered, and evaporated to dryness. Fuligokali is in the form of a black powder, or of scales, very soluble in water, and having an empyreumatic odour and mild alkaline taste. It is used in the same affections as *anthrakokali*. The dose is two or three grains, repeated several times a day. An ointment, containing from 16 to 32 grains to the ounce of lard, was found by Dr. Gibert, of Paris, to be detersive, resolvent, and gently stimulant. (See a paper by A. Duhamel, in the *Am. Journ. of Pharm.*, xiv. 284.) B.

FUMARIA OFFICINALIS. *Fumitory.* A small annual European plant, naturalized in this country, growing in cultivated grounds, and flowering from May to August. It was formerly considerably employed as a medicine, and is still used in Europe. The leaves are the officinal part. They are inodorous, have a bitter saline taste, and are very succulent, yielding by expression a juice which has the sensible and medicinal properties of the plant. An extract, prepared by evaporating the expressed juice or a decoction of the leaves, throws out upon its surface a copious saline efflorescence. The plant, indeed, abounds in saline substances, and to these, in connection with its bitter extractive, its medical virtues have been ascribed. Recently, however, M. Hannon, of Belgium, has ascertained the presence in fumitory of an alkaloid, called *fumarin* (*fumarina*), to which he ascribes the effects of the plant. He obtained it by treating the pulp of the leaves with concentrated acetic acid, with the aid of heat, filtering, evaporating the liquid, treating the extract with boiling alcohol, filtering the alcoholic solution, and, finally, decolorizing, and evaporating so that crystals might form. The acetate thus procured was decomposed by the alkalies, and yielded the fumarina. Fumitory has been considered gently tonic, alterative, and, in large doses, laxative and diuretic. But M. Hannon considers it mainly sedative, and states that its prolonged use diminishes plethora, and may even produce anæmia. He has found fumarina, in the dose of about one-third or one-fourth of a grain, to be moderately excitant; in that of three grains, to be at first irritant and afterwards sedative. (*Ann. de Thérap.*, 1854, p. 78.) Both in ancient and modern times fumitory has been esteemed a valuable remedy in visceral obstructions, particularly those of the liver, in scorbutic affections, and in various troublesome eruptive diseases. Cullen speaks favourably of it in these last complaints. He gave two ounces of the expressed juice twice a day. Others have prescribed it in much larger quantities. The leaves, either fresh or dried, may be used in decoction, without precise limitation as regards the dose. The inspissated juice and an extract of the dried leaves have also been employed. W.

FUSTIC. A yellow dye-wood, obtained from *Morus tinctoria* (*Broussonetia tinctoria*, Kunth), a tree growing in the West Indies and South America. It is not used in medicine or pharmacy. According to Bancroft, two different woods bear in England the name of fustic, one the product of the tree just mentioned, distinguished as *old fustic*, probably from the greater magnitude of the billets in which it is imported; the other derived from the *Rhus Cotinus* or *Venice sumach*, and called *young fustic*, or sometimes *Hungarian fustic*. The wood of M. tinctoria owes its colouring properties to two principles, which have been isolated by R. Wagner; one denominated *morin*, and the other *moritannic acid*, from its resemblance to tannin. (See *Chem. Gaz.*, ix. 1, 21, and 241.) From the fustic of Rhus Cotinus or Hungarian fustic, M. Chevreul extracted a yellow colouring matter, in small crystalline needles when pure, which he called *fissetine* or *fisetic* acid, and a red substance, of which he was unable to say whether it pre-existed in the fustic, or was formed from the fissetine. (*Chem. News*, March 17, 1865, p. 126.) W.

GALANGAL. *Galanga.* Two varieties are described by authors, the *galanga major* and *galanga minor*, or *large* and *small galangal*. They are considered by some as the roots of different plants; but there is reason to believe that they are both derived from *Maranta Galanga* of Linn. (*Alpinia Galanga* of Willd.), and that they differ in consequence of the different stages of growth at which they are collected. They are brought from the East Indies. The *larger variety* is cylindrical, three or four inches long, as thick as the thumb or thicker, often forked, reddish-brown externally, slightly striated longitudinally,

marked with whitish circular rings, orange-brown internally, rather hard and fibrous, difficultly pulverizable, of an agreeable aromatic odour, and a pungent, hot, spicy, permanent taste. The *small galangal* resembles the preceding in shape, but is smaller, not exceeding the little finger in thickness, of a darker colour, and of a stronger taste and smell. According to Morin, galangal contains a volatile oil, an acrid resin, extractive, gum, bassorin, and lignin. A. Vogel, jun., found also starch and fixed oil. (*Pharm. Cent. Blatt*, 1844, p. 158.) R. Brandes discovered a peculiar crystallizable substance called *kempferid*. (*Annal. der Pharm.*, xxxii. 311.) The active principles are the volatile oil and acrid resin. The medical effects of galangal are those of a stimulant aromatic. It was known to the ancient Greeks and Arabians, and formerly entered into numerous compound preparations. At present it is seldom employed. Its dose is from fifteen to thirty grains in substance, and twice as much in infusion. W.

GALEGA OFFICINALIS. *Goat's Rue.* A perennial herb, growing in the South of Europe, and sometimes cultivated in gardens. It is without smell unless bruised, when it emits a disagreeable odour. Its taste is unpleasantly bitter and somewhat rough, and when chewed it stains the saliva yellowish-brown. In former times it was much employed as a remedy in malignant fevers, the plague, the bites of serpents, worms, &c.; but it has fallen into merited neglect. The roots of *Galega Virginiana*, a native of the United States, are said to be diaphoretic and powerfully anthelmintic. They are given in decoction. W.

GALIUM APARINE. *Cleavers. Goose-grass.* This is an annual, succulent plant, common to Europe and the United States, growing in cultivated grounds, and along fences and hedges. It is inodorous, and has a bitterish, herbaceous, somewhat acrid taste. Analyzed by Schwartz, it was found, besides chlorophyll, starch, and other principles common to all plants, to contain three distinct acids, viz., a variety of tannic acid, which he names *galitannic acid*, citric acid, and a peculiar acid, previously discovered by Schwartz and Rochleder, and named *rubichloric acid*. (*Pharm. Journ.*, xii. 190.) The expressed juice is said to be aperient, diuretic, and antiscorbutic, and has been used in dropsy, congestion of the spleen, scrofula, and scorbutic eruptions. In the last complaint it has been thought peculiarly useful. Three ounces of the juice may be taken twice a day. Dr. Winn, of Truro, Cornwall, has called the attention of the profession to this medicine. Several persons in his neighbourhood had been cured of lepra by a decoction of the plant; and he had himself employed it with great advantage not only in this but other cutaneous diseases. At first he gave it in the form of decoction made by boiling a handful of the recent herb in a quart of water for twenty minutes, of which a tumblerful was given three times a day; but he afterwards preferred the inspissated juice, in the form of a fluid extract, of which ʒj should represent half a pint of the decoction. (*London Med. Times and Gaz.*, Feb. 1854, page 144.) The fresh herb, in the form of ointment or decoction, has been applied externally to scrofulous swellings with supposed advantage. W.

GALIUM VERUM. *Yellow Ladies' Bedstraw. Cheese rennet.* This species of Galium is perennial, and a native of Europe. The flowers, which are yellow, have a peculiar, agreeable odour, and have been given in nervous affections, with a view to their supposed antispasmodic powers. The herb is inodorous, but has an astringent, acidulous, bitterish taste. The property of coagulating milk was formerly ascribed to it, but is certainly not constant, as the experiment has been frequently tried without success. The bruised plant is sometimes used to colour cheese yellow, being introduced into the milk before coagulation. It is also used for dyeing yellow. The roots of this and of most other species dye red; and the plant, eaten by animals, colours the bones like madder. This plant was analyzed by Schwartz, and found to contain the same principles as *G. Aparine*, mentioned above. It was formerly highly esteemed as a remedy in epilepsy and hysteria, and was applied externally in cutaneous eruptions. It may be employed in the form either of the recently expressed juice, or of a decoction prepared from the fresh plant. Its medical properties, however, are feeble. Testimony has been given in France to the special efficacy of *Galium palustre* in epilepsy. (*Ann. de Thérap.*, 1863, p. 77.)

Of the American species, *G. tinctorium* is closely allied in properties to G. verum. It is said to be useful in cutaneous diseases; and the root is employed by the Indians for staining their feathers and other ornaments red. W.

GARDENIA GRANDIFLORA. A Chinese tree, the fruit of which is employed in dyeing the yellow robes of the mandarins. It has acquired some additional interest from a recent chemical examination of the fruit by Lorenz Mayer, in the laboratory of Rochleder, the result of which was the discovery of a colouring substance, which proved to be identical with that of saffron, and to which, therefore, the name of *crocin* was given. In powder, it is of a bright-red colour, and is soluble in water and alcohol. By treatment with muriatic acid, it yields another colouring substance called *crocetin*, which is a true dye-stuff. (*Chem. Gaz.*, Sept. 1, 1858, p. 331.) The fruit of another species, *G. campanulata*, growing in the forests of Chittagong, in India, is said to be used by the natives as a cathartic and anthelmintic. (Lindley, *Flor. Med.*, p. 434.) W.

GENISTA TINCTORIA. *Dyers' Broom. Dyers' Weed. Green Weed.* A low shrub, growing wild in Europe, and sometimes cultivated in this country in gardens. The flowering tops of the plant are employed to dye yellow, whence its name was derived. Both

these and the seeds have been used in medicine. They are said to be purgative and even emetic, especially the seeds, which were formerly given as a cathartic in the dose of a drachm and a half. By some authors they are said to be diuretic, and to be useful in dropsy. The plant has been long used as a preventive of hydrophobia by the peasants of Podolia, the Ukraine, and other provinces of Russia. They employ it in the form of strong decoction, both internally and locally, in connection with *Rhus coriaria*, and persevere with it for six weeks. The trials made with it in other parts of Europe have failed. W.

GERANIUM ROBERTIANUM. *Herb Robert.* This species of Geranium grows wild both in Europe and the United States, but is rare in this country; and Pursh states that the American plant is destitute of the heavy smell by which the European is so well known, though the two agree in all other respects. The herb has a disagreeable, bitterish, astringent taste, and imparts its virtues to boiling water. It has been used internally in intermittent fever, consumption, hemorrhages, nephritic complaints, jaundice, &c., has been employed as a gargle in affections of the throat, and has been applied externally as a resolvent to swollen breasts and other tumours. W.

GLASS OF ANTIMONY. *Vitrum Antimonii.* This is prepared from the tersulphuret of antimony by a partial roasting and subsequent fusion. The tersulphuret, reduced to coarse powder, is strewed upon a shallow, unglazed earthen vessel, and heated gently and slowly, being continually stirred to prevent it from running into lumps. White vapours of sulphurous acid arise; and, when these cease, the heat is increased a little to reproduce them. The roasting is continued in this manner until, at a red heat, no more vapours are given off. The matter is then melted in a crucible with an intense heat, and kept in a state of fusion until it assumes the appearance of melted glass, when it is poured out on a heated brass plate. In this process, part of the sulphur of the tersulphuret is driven off by the roasting; while the portion of antimony which loses its sulphur becomes teroxidized. The roasted matter, therefore, consists of teroxide of antimony and undecomposed tersulphuret; and these, by uniting during the fusion, form the glass. Glass of antimony is in thin irregular pieces, with a vitreous fracture, and a metallic steel-gray lustre. When well prepared it is transparent, and, upon being held between the eye and the light, appears of a rich orange-red or garnet colour; but if of inferior quality it is black and opaque. It is hard and brittle, and rings when struck with a hard substance. It is insoluble in water, but soluble in acids and cream of tartar, with the exception of a few red flocculi. Its essential constituents are the teroxide and tersulphuret, united in variable proportions. When of good quality it consists of about eight parts of teroxide to one of tersulphuret. It usually contains about 5 per cent. of silica, and three of sesquioxide of iron, which are derived from the crucible, and to the former of which the vitrification of the product is owing. When good it is dissolved, with the exception of a few red flocculi, in strong muriatic acid. An excess of the silica is shown by the acid leaving a gelatinous residue, and the iron may be detected by ferrocyanide of potassium, and its amount judged of by the bulk of the precipitate and the depth of its blue colour. Sometimes *glass of lead* is sold for glass of antimony, a fraud readily detected by the difference between the two substances in specific gravity; glass of lead having a density of nearly seven, while that of glass of antimony is not quite five.

Medical Properties, &c. Glass of antimony is an active antimonial; but, owing to its variable composition and unequal operation, it is at present very seldom used. When the levigated powder is mixed with one-eighth of its weight of melted yellow wax, and the mixture roasted over a slow fire, with constant stirring, until it ceases to exhale vapours, a coal-like pulverizable mass is formed, which is the *cerated glass of antimony*, a preparation formerly included in the Edinburgh Pharmacopœia. B.

GLECHOMA HEDERACEA. *Nepeta Glechoma. Ground-ivy.* A small perennial herb, indigenous in Europe and the United States, and growing in shady, grassy places, as in orchards and along fences and hedges. It belongs to the family of labiate plants, and shares their general properties. The herb was formerly officinal, and still enjoys some credit as a domestic remedy. It has a peculiar disagreeable odour, and a bitterish, somewhat aromatic taste, and imparts its properties to boiling water. It is said to be gently stimulant and tonic, with, perhaps, a peculiar direction to the lungs and kidneys. It has also been considered aperient. It has been most used in chronic affections of the pulmonary and urinary organs, and at one time had considerable reputation as a remedy in consumption. It has also been employed as a vulnerary and errhine. The usual form for exhibition was that of infusion, of which a dose was given containing the virtues of half a drachm or a drachm of the herb. W.

GLOBULARIA ALYPUM. *Wild Senna of Europe.* This is a small shrub, growing on the European shores of the Mediterranean, the leaves of which have been occasionally used as a cathartic since the middle ages. Dr. Gustave Planchon, of Montpellier, France, in an essay on the plants of this genus, published in 1859, states that the leaves of this species are a mild and efficient cathartic, without the griping properties of senna, and without leaving behind a tendency to constipate like rhubarb, which, however, it resembles in tonic power. One ounce is given for a dose in decoction. It is unknown in this country. (See *Pharm. Journ.*, xvi. 426.) W.

GLUE. An impure form of gelatin, obtained from various animal substances by boiling them in water, straining the solution, and evaporating it till upon cooling it assumes the consistence of jelly. The soft mass which results is then divided into thin slices, which are dried in the open air. Glue, when of good quality, is hard and brittle, of a colour varying from light-yellow to brown, and equally transparent throughout. It softens and swells very much in cold water, without dissolving; but is readily dissolved by hot water. It is employed chiefly for cementing pieces of wood, being generally too impure for the purpose of a test, or as an article of food. An *elastic and imputrescible preparation of glue*, useful for various purposes in the arts and in medicine, may be made by dissolving glue in water by means of a water-bath, concentrating the solution, then adding a weight of glycerin nearly equal to that of the glue employed, thoroughly mixing, evaporating the residue of the water, and finally pouring into moulds, or on a marble slab. It is especially applicable to the preparation of artificial anatomical specimens. (*Journ. de Pharm.*, Jan. 1857, p. 23.) A good *liquid glue* may be made by rubbing up in two pints of rain-water, with the heat of a water-bath, 16 ounces of the best white glue and 4 ounces of dry white lead, until thoroughly mixed, then adding four fluidounces of alcohol, and continuing the heat and the agitation for a few minutes. The mixture is to be poured into bottles while still hot. (*Drug. Circular*, Oct. 1866.) A *liquid glue* may also be readily made by mixing in a stoppered bottle 38 parts of glue, properly divided, and 100 parts of acetic acid of commerce, the latter of which dissolves the glue as water dissolves gum. On exposure the acid evaporates, leaving the glue unchanged. (*Journ. de Pharm.*, 3e sér., xlvi. 35.) A mode of preparing *strong liquid glue*, recommended by M. Knaff, is to take three parts of good glue in small pieces, cover it with 8 parts of water, and, after having allowed it to stand for some hours, add half a part of muriatic acid and three-fourths of a part of sulphate of zinc, and expose the whole for 10 or 12 hours to a heat from 178° to 189° F. This does not gelatinize and keeps well. (*Am. Journ. of Pharm.*, July, 1868, p. 330; from *Journ. de Pharm.*)

Capsules of Gelatin. Glue has within a few years been applied to an important practical purpose in pharmacy. Certain medicines are so offensive to the taste, and consequently so apt to sicken the stomach, that it is highly desirable to administer them in such a way as to prevent their contact with the tongue and palate. This object is fully accomplished, so far as regards many disagreeable liquid medicines, by the use of the *capsules of gelatin*, invented by M. Dublanc, of Paris. These are prepared from the purest glue in the following manner. Small pouches made of fine skin, of an oval form, are attached by a waxed thread to the smaller extremity of a hollow elongated metallic cone, which is bent towards its point, and has its base closed by a cover, which is screwed so as to make the instrument air-tight. Into this conical tube sufficient mercury is poured to fill the pouch, which, thus distended, is dipped into a concentrated solution, made by heating six parts of pure glue with one of sweetened water, and is afterwards exposed to heat in a vertical position, so as to dry the layer of gelatin which it has received. In the same manner a second coating may be given, and the process again repeated till a sufficient thickness has been obtained. The cone being then reversed, the mercury flows out of the pouch, which collapses, and allows the capsule of gelatin to be removed. Into this the medicine may now be introduced, care being taken to avoid any contact with the outer surface of the capsule. The opening is next to be closed by means of a thin lamina of gelatin previously softened by steam; and a solution of the same substance should be applied to the edges by means of a camel's-hair pencil. Another mode of preparing the capsules is as follows. Take a cylinder of iron or hard wood, four lines in diameter and a few inches long, and smoothly rounded at one end. Dip half an inch of this end first into a saturated warm alcoholic solution of soap, and afterwards, when the soap has concreted upon the surface, into a concentrated hot solution of gelatin, and repeat the latter immersion once or oftener, if it be desired to have a firm capsule. When the glue has concreted, remove the capsule. A top for it may be made in the same way, and, after the body has been filled with the liquid to be given, is to be applied, and secured by rubbing a camel's-hair pencil moistened with hot water over the line of junction. (*Med. Exam.*, N. S., i. 441.) M. Mothès considers the following plan of preparing the capsules the most convenient. He has a number of assorted "copper olives" prepared, covers their surface with a layer of something to prevent oxidation, immerses them in a sweetened and aromatized concentrated solution of gelatin, then places them vertically on boards to cool, and before complete desiccation removes the capsules, places them on sieves, and dries them by a stove-heat. (*Journ. de Pharm.*, xvii. 204.) Mr. Redwood gives the following process, which is a modification of the second method above described. A polished bulb of iron, ivory, or bone, of the size and shape of the capsules required, and connected by a slender rod with a handle, is first greased by rubbing with an oiled cloth, and then dipped into a solution of gelatin made as above directed. Upon being withdrawn, it is held for a short time so as to allow the excess of the solution to run off, and then fixed with the handle in a board, the coated bulb being upward, until the coating becomes cold and firm. The capsule is now removed by the fingers, and further dried by exposure on a tray. A number of capsules having been prepared, they are placed each in a small cell upon a board, with their mouths upward; and the liquid they are to contain is introduced by means of a syringe

with a fine point. Their mouths are then closed with a drop of the solution of gelatin applied by means of a camel's-hair pencil, which is afterwards strengthened by an additional coating, given by dipping the mouth of the capsule into the solution diluted with a little water. (*Redwood's Supplement*, p. 664.) The capsules may be made of such a capacity as to contain from ten to fifteen grains of copaiba.

A new application of gelatin has been proposed by Mr. A. F. Haselden; for the formation, namely, of capsules to the tops of bottles, as a substitute for sealing wax or resin. For this purpose, to a pound of gelatin, after it has been melted with as little water as necessary, an ounce and a half of glycerin are to be added to give it pliability and toughness, and a little liquid cochineal to colour it; the cork and neck of the bottle are then dipped into the liquid, which gives them a coating, which may be rendered as thick as required by repeating the immersion if necessary. These are the essentials of the operation, but various manipulations are necessary to meet all the demands of the case, for which we refer to Mr. Haselden's article in the *Pharm. Journ.* (March, 1866, p. 450). W.

GNAPHALIUM MARGARITACEUM. *Cudweed. Life-everlasting.* An indigenous herbaceous perennial, growing in fields and woods, and flowering in August. The herb of this species and of *G. polycephalum*, or *sweet-scented life-everlasting*, is sometimes used, in the form of tea, by the country people, in diseases of the chest and of the bowels, and in hemorrhagic affections, and externally, in the way of fomentation, in bruises, languid tumours, and other local complaints; but it probably possesses little medical virtue. Shoepf says that it is anodyne. In Europe different species of Gnaphalium are also occasionally employed for similar purposes. W.

GOLD. *Aurum.* The preparations of this metal were introduced to the notice of physicians by Dr. Chrestien, of Montpellier, in 1810. They are employed both internally and by friction on the tongue and gums. The principal affections in which they have been recommended are secondary syphilis, syphilitic ulcerations, scrofula, and inveterate eruptions, particularly those of a leprous character. The chief preparations which have been employed, up to the present time, are metallic gold in a finely divided state, the oxide (teroxide or auric acid), the chloride (terchloride), the iodide, the double chloride of gold and sodium, the chloroaurate of ammonia (a compound of terchloride of gold and muriate of ammonia), and the cyanide (tercyanide) of gold. *Gold in powder* may be obtained by rubbing up gold-leaf with 10 or 12 times its weight of sulphate of potassa until brilliant particles are no longer visible, and then washing away the sulphate with boiling water. The *oxide* may be procured by treating the nitromuriatic solution of gold with an excess of magnesia, and washing the precipitate, first with water, and afterwards with dilute nitric acid. This process being tedious, M. L. Figuier prefers to obtain the oxide by precipitating the cold solution of chloride of gold, rendered strongly alkaline by caustic potassa, with a solution of chloride of barium. The precipitate, consisting of aurate of baryta, is then treated with dilute nitric acid, which dissolves the baryta and leaves the oxide of gold pure. Ten parts of gold, thus treated, produced 11·75 parts of oxide; while the same quantity of gold by the magnesia process only yielded 9 parts. (*Journ. de Pharm.*, Dec. 1847.) The *chloride* is obtained by dissolving pure gold in three times its weight of nitromuriatic acid, with the aid of a moderate heat. The solution is evaporated by a gentle heat nearly to dryness, being at the same time stirred with a glass rod. It is in the form of a crystalline mass of a deep-red colour. Its solution has a fine yellow tint. Being deliquescent, it requires to be kept in ground-stoppered bottles. The *iodide* may be made by precipitating a solution of terchloride of gold by one of iodide of potassium, and washing the precipitate with alcohol to remove the excess of iodine. It is of a greenish-yellow colour, and, when heated in a porcelain crucible, is resolved into iodine vapours and a residue of pure gold. *Chloride of gold and sodium* is prepared by dissolving four parts of gold in nitromuriatic acid, evaporating the solution to dryness, and dissolving the dry mass in eight times its weight of distilled water. To this solution one part of pure decrepitated common salt is added, previously dissolved in four parts of water. The mixed solution is then evaporated to dryness, being in the mean time constantly stirred with a glass rod. The salt is of a golden-yellow colour, and, when crystallized, is in the form of long prismatic crystals, unalterable in the air. The *chloroaurate of ammonia* is formed by dissolving one part of the terchloride of gold and two parts of muriate of ammonia in distilled water, assisted by a few drops of nitromuriatic acid, and evaporating the solution to dryness by a gentle heat. The *cyanide* is best obtained, according to M. Oscar Figuier, as follows. Prepare the chloride of gold as neutral as possible by repeated solutions and crystallizations; and to the solution of this salt add, very cautiously, avoiding any excess, a solution of *pure* cyanide of potassium, so long as any precipitate falls. (See *Potassii Cyanidum.*) The precipitate, consisting of cyanide of gold, is to be washed with pure water, and dried in the dark. Gold in powder, and the oxide, chloride, iodide, sodio-chloride, and cyanide are officinal in the French Codex.

The preparations of gold are decidedly poisonous, though in different degrees. The chloride is most virulent, and, according to Dr. Chrestien, is even more active than corrosive sublimate. In an overdose, it produces pain, inflammation, and even ulceration of the stomach and bowels, and otherwise acts as a corrosive poison. The general effect of these preparations, in moderate doses, is to produce increased fulness and frequency of

the pulse, and to augment the urine and insensible perspiration, without interfering with the appetite or the regular action of the bowels; but, if the dose be pushed too far, general irritation is apt to be produced, inflammation seizes upon some organ, according to the predisposition of the individual, and fever is developed.

Gold in powder, the oxide, chloride, and *iodide* are not as much used as the double chloride of gold and sodium. The oxide may be given in the form of pill, containing the tenth of a grain, in scrofula and lymphatic swellings, beginning with one pill daily, and afterwards gradually increasing to seven or eight in 24 hours. The chloride has been used with advantage as a caustic in lupus, and in syphilitic tubercles and ulcers by M. Chavannes. The iodide may be given in the same cases with the other preparations. The dose is from the fifteenth to the tenth of a grain.

Chloride of gold and sodium is the preparation of gold most commonly employed. It may be given in lozenges, each containing the twelfth of a grain, by mixing immediately five grains of the salt with an ounce of powdered sugar, and making the whole with mucilage of tragacanth into a proper mass, to be divided into sixty lozenges. Pills, containing the same dose, may be formed by dissolving ten grains of the dried salt in a drachm of distilled water, and forming the solution into a pilular mass with a mixture of four drachms of potato starch and one drachm of gum arabic, to be divided into one hundred and twenty pills. (*Journ. de Pharm.*, xx. 648.) For frictions on the gums and tongue, Chrestien recommends the following formula: Crystallized chloride of gold and sodium one grain; powdered orris root, deprived of its soluble parts by alcohol and water, and dried, two grains. Mix. At first the fifteenth part of this powder is used daily by frictions; afterwards the fourteenth, the thirteenth, &c., until, increasing gradually, the tenth or eighth part is employed. The use of four grains of the salt in this way is said commonly to cure bad cases of recent syphilis; such, for example, as are characterized by the coexistence of chancres, warts, and buboes. In preparing this powder, lycopodium may be substituted for the orris. MM. Rouault and Debreque have used this preparation of gold with success, in daily frictions for some minutes to the tongue, gums, and inside of the cheeks, for the resolution of chronic glandular tumours, especially those which occur in the neck in the form of a chain. The patient should swallow his saliva, while the frictions are practised. (*B. and F. Medico-chir. Rev*, Am. ed., July, 1857, p. 172.)

Chloroaurate of ammonia has been recommended by Bouchardat in amenorrhœa, and dysmenorrhœa in debilitated subjects, in the dose of about the tenth of a grain. A grain may be dissolved in five teaspoonfuls of alcohol and five of water, and a teaspoonful given morning and evening, mixed with sweetened water.

Cyanide of gold is employed, like the chloride of gold and sodium, mixed with inert powders by friction, and in the form of pill. The fifteenth of a grain may be rubbed into the gums daily for fifteen days, next the fourteenth of a grain for fourteen days, and so on, increasing until the dose amounts to the ninth or eighth of a grain. The dose for internal exhibition is the eighteenth of a grain, gradually increased to the eighth. Cyanide of gold has been found useful in the treatment of syphilis and scrofula by M. Pourché, and is said to be less exciting than the double chloride, when used in those diseases.

The different medicinal compounds of gold should not be prepared in pill, powder, or otherwise, until they are wanted for use; as they are liable to undergo decomposition when kept. They should be carefully secluded from the light. B.

GRASS-TREE GUM. An Australian product, said to be obtained by exudation from different species of Xanthorrhœa, especially *X. hastilis*. As described by Mr. P. L. Simmonds, it is of a resinous character, usually as found in the markets in the state of small fragments or coarse powder, resulting from the breaking up of the larger brittle masses in which it first occurs. It is of a deep reddish-yellow colour in mass, but greenish-yellow in powder. It does not dissolve in the mouth when chewed, nor adhere to the teeth, but has a slightly astringent and aromatic flavour. It melts with heat, and at a higher temperature takes fire in the air, burning with a smoky flame, and emitting a fragrant odour not unlike that of balsam of tolu. It yields carbazotic acid largely under the action of nitric acid. It is recommended as a source of gas for illumination. The natives and early settlers are said to have used it as a medicine in diarrhœa. It is obtainable in inexhaustible quantities; as the plants producing it are abundant throughout almost the whole of Australia. (*Am. Journ. of Pharm.*, Sept. 1866, p. 465; from *Med Press and Circular.*) W.

GRATIOLA OFFICINALIS. *Hedge-hyssop.* This is a perennial herb, indigenous in the South of Europe, where it flourishes in meadows and other moist grounds. The whole herb is used. It is nearly inodorous, but has a bitter nauseous taste. Both water and alcohol extract its active properties. Its chemical constitution has been investigated by Dr. F. G. Walz, who found the following constituents; 1. *gratiolin*, 2. *gratiosolin*, 3. *gratiolacrin*, 4. fixed oil, 5. a brown resin, 6. tannic acid, and 7. a volatile acid, the *antirrhinic* acid, which exists in many of the *Scrophularineæ*. Each of the peculiar substances mentioned consists of carbon, hydrogen, and oxygen; the formula of gratiolin being $C_{40}H_{34}O_{14}$, that of gratiosolin $C_{46}H_{42}O_{25}$, and that of gratiolacrin $C_{31}H_{29}O_4$. For the mode of preparing them the reader is referred to the *Am. Journ. of Pharm.* (July, 1859, p. 340), and, for a

fuller account of them, to the *Chemisches Central Blatt* (Oct. 6, 1858, p. 689). Hedge-hyssop is a drastic cathartic and emetic, possessing also diuretic properties, and is employed on the continent of Europe in dropsy, jaundice, worms, chronic hepatic affections, scrofula, and various other complaints. With us it is almost unknown as a remedy. The dose of the powdered herb is from fifteen to thirty grains; of the infusion, made in the proportion of half an ounce to the pint of boiling water, half a fluidounce. W.

GRINDELIA ROBUSTA. (*Torrey & Gray, Flora of N. America*, ii. 247.) Under the name of Grindelia robusta, Dr. H. Gibbons, in the *Pacific Med. and Surg. Journal*, notices an herbaceous plant, abundant in California, especially in hilly situations, which is said to have extraordinary efficacy in asthma. It is described as having an erect stem, a foot or two high, without branches, and terminating in a spherical head of compound flowers, the rays of which are white, and about half an inch in length. Upon the calyx is usually to be seen a drop or two of a milky resinous juice, which is characteristic of the plant. The herb has a balsamic odour and taste; and a syrup made from the decoction is not unpalatable, and taken internally acts as an expectorant. But the chief value of the plant is as a remedy in asthma. A clergyman who had suffered extremely from that disease, and in whose case all the remedies usually given had been tried in vain, took, on going to bed, a wineglassful of syrup made from the herb, slept soundly through the night, and, under its continued use, had not been compelled for seven months to pass one night out of bed. (*Med. and Surg. Reporter*, Jan. 22, 1867, p. 520.) W.

GROUND NUTS. *Pea Nuts.* The fruit of *Arachis hypogæa*, a leguminous, annual plant, indigenous probably in Africa and South America, and abundantly cultivated in our Southern States, and elsewhere. A remarkable property of the plant is that its fruit ripens under the surface of the ground, into which the pods penetrate in the progress of their growth. The seeds constitute the well-known ground nuts of our markets, which consist of a dry, brittle envelope, and a yellowish-white kernel. These when roasted constitute for many a very agreeable article of food, and in the South are said to be much used as a substitute for coffee. They are, however, chiefly valuable on account of their richness in a fixed oil, which amounts to more than 20 per cent., and which is largely prepared in this country as an article of commerce. It is obtained by expression; the nuts being ground into a paste, and moderately heated before being submitted to pressure. As described by Mr. Jonas Winter, the oil has a bright-yellow colour, the characteristic odour of the fruit, and a mild not unpleasant taste. It is soluble in all proportions in ether, chloroform, and benzine, but insoluble in alcohol. Its sp. gr. is 0·918 at 60° F. At 38° it thickens, at 32° congeals imperfectly, and at 620° is decomposed, giving out spontaneously inflammable vapours. Mr. Winter made experiments to ascertain how far it might be employed with advantage in pharmacy, and found that it answered well in the preparation of cerates and ointments; but would not serve as a substitute for olive oil in the preparation of the lead-plaster. It is a non-drying oil, and will not therefore answer for painting; but it is used for various purposes in the arts, as for lubricating machinery, and in the manufacture of woollen cloths; and would serve for burning in lamps, giving even a better light than sperm oil. (*Am. Journ. of Pharm.*, July, 1860, p. 292.) W.

GUACO. This name is given in Central and South America, and the West Indies, to various plants having supposed alexipharmic properties, and belonging to the genera *Mikania* and *Aristolochia;* but it is to the different species of the former genus that the appellative properly belongs, especially to *Mikania Guaco*, described by Humboldt and Bonpland. (*Pl. Æq.* ii. 84.) The genus Mikania belongs to the Linnæan class and order *Syngenesia Æqualis*, and to the natural order *Asteraceæ*. The plants are closely allied to the Eupatoria. For their generic character, see *Lindley's Flora Medica*, and *Griffith's Medical Botany*. Mikania Guaco is described as having twining stems, with round, sulcate, and hairy branches; ovate, subacuminate, remotely dentate leaves, somewhat narrowed at the base, rough above, and hairy beneath; and flowers in opposite axillary corymbs. The plant is a native of intertropical America, and has been introduced into the W. India Islands from the continent. The leaves are the part used. In the recent state they have a bitter taste, and a strong disagreeable odour; but their sensible properties and medical virtues are impaired by drying.

This and other plants have long been employed by the natives as a preventive and cure of the bites of poisonous serpents. This application of them was first made known by Mutis; and his account was confirmed by Humboldt and Bonpland. Very naturally the guaco came afterwards to be considered as antisyphilitic. The medicine has also been employed as a febrifuge and anthelmintic, and a few years since attracted considerable attention for its supposed prophylactic and remedial powers in epidemic cholera and chronic diarrhœa. According to Guibourt, however, the medicine used in France, under the name of guaco, was composed almost entirely of three or four species of Aristolochia, which, as before stated, are used in some parts of Mexico, as antidotes for snake poison, under the name of guaco. The medicine has, moreover, been recommended in chronic rheumatism, both internally and locally, and as an application to bites of insects, bruises and sprains, and atonic deafness. The probability is that, like eupatorium, it has simply the virtues of a mild tonic, and gentle stimulant to the secretions. It

is best employed in the recent state. The natives, when employing it as a counterpoison, apply the bruised leaves and expressed juice to the bite, and at the same time drink of the infusion. It is highly recommended by Dr. E. W. Pritchard in the gouty paroxysm, in which he has seldom known it to fail giving more or less relief. He gives from half a drachm to a drachm of the tincture every four hours, and applies it locally at the same time. (*Pharm. Journ.*, Nov. 1861, p. 288.) The preparations recommended for internal use are chiefly an infusion and tincture, the former made in the proportion of an ounce of the leaves to a pint of boiling water, the latter of about a pound to the gallon of proof spirit. The dose may be about the same as that of analogous preparations of eupatorium. (See *Lond. Med. Times and Gaz.*, Dec. 1852, p. 651; and *Journ. de Pharm.*, 3e sér., xx. 357.) The result of a long and close investigation into the natural history of guaco by the distinguished Guibourt is, that the *Mikania Guaco*, instead of possessing, as has been asserted, a strong, penetrating, and nauseous odour, is in fact inodorous, and destitute of all active properties; and that the strongly aromatic plants which have been employed under the name of guaco, all belong to the genus Aristolochia, especially *A. cymbifera* of Martius, growing in Brazil, after this *A. maxima* (De Cand.), and in less degree *A geminiflora* of Kunth. (*Journ. de Pharm.*, Août, 1867, p. 99.) W.

GUANO *Bird-manure.* This is a valuable manure, consisting of the decomposed excrement of countless aquatic birds, which has accumulated for ages on certain barren and uninhabited islets of the western coast of South America, and in other localities throughout the world. The best comes from Peru, and will be here described. It is a coarse dry powder of a brown colour. Exposed to the air it absorbs moisture, and becomes somewhat sticky. Its smell is offensive, and slightly ammoniacal. With the powder are intermingled friable lumps, which exhibit in their inside whitish specks, and which, when exposed to the air, fall to powder, exhaling an ammoniacal smell. It is soluble in great part in water, and the solution formed contains chiefly oxalate of ammonia. When exposed to heat it blackens, burns with a slight flame, exhales the smell of ammonia, and leaves a whitish ash, varying in amount from 27 to 35 per cent. The guanos of commerce vary very much in composition, from the best Peruvian to the inferior sorts, which have scarcely any value as fertilizers. A good specimen of guano, analyzed by Fownes, consisted of about two-thirds oxalate of ammonia, and one-third earthy and alkaline phosphates, &c. The source of oxalate of ammonia is undoubtedly the uric acid, originally in the excrement, and which is often found undecomposed in the guano. The value of guano as a fertilizer depends chiefly upon the proportion of the organic ingredients; the phosphates being of secondary importance. M. E. Baudrimont infers, from the analysis of seventeen samples of Peruvian guano, that the proportion of nitrogen may be obtained approximately by dividing the amount of the organic matters by five. The samples varied greatly in value. (*Journ. de Pharm.*, Oct. 1857.) Crystals of carbonate of ammonia have been observed in guano. Columbian guano was found by Dr. C. Morfit, of Baltimore, to be rich in phosphoric acid and lime. (*Chem. Gaz.*, Dec. 1, 1855.) Unger obtained from Peruvian guano, in 1845, a peculiar substance, analogous to uric (zanthic) oxide, called *guanin*. It forms crystallizable salts with acids, and has the formula $C_{10}H_5N_5O_2$. The accuracy of this formula has been confirmed by MM. Neubauer and Kerner.

In South America, guano has been used with benefit, internally and externally, as a remedy in the different forms of lepra. The late Prof. Horner, of Philadelphia, employed it as a cataplasm, mixed with an equal quantity of potters' clay, in a case of chronic inflammation of the knee-joint. In this proportion it blistered the surface; and cataplasms were afterwards adopted, containing one-third and one-fourth of guano. (*Med. Exam.*, Feb. 1852, p. 69.) Prof. Horner attributed the revulsive effect of guano to urate of ammonia; but the best authorities state that oxalate of ammonia is the characteristic salt of this substance. Since 1852, guano has been a good deal used in cutaneous diseases, especially in ecthyma, eczema, and tinea capitis. It is employed in the form of bath, lotion, and ointment. Récamier prescribed baths in these diseases, each bath containing sixteen ounces of guano; and the practice has been imitated with success by M. Desmartis, and by M. Van der Abeele, of Belgium. The lotion may be made by exhausting an ounce of guano with a pint of boiling water, and filtering the solution. The ointment is formed of various strengths, from one to five parts of guano to fifteen of lard. M. C. Girardin prepares an extract of guano by exhausting it with alcohol, diluted with twice its bulk of water, and evaporating the solution to dryness. Of this extract he makes an ointment, useful in eruptions, by mixing it with three parts of lard, and also a syrup, flavoured with vanilla, of which the dose is a fluidrachm, containing a grain of the extract, to be given in scrofula. The variable composition of guano must always form a serious objection to its therapeutic use. B.

GYNOCARDIA ODORATA. *Chaulmoogra.* This is an East India plant, the fruit of which has been employed, with asserted benefit, in elephantiasis or the leprosy of the East. The fruit is a succulent indehiscent pericarp, which yields a fixed oil by expression. The seeds are used internally, and the oil applied to the ulcers. Dr. Mouat has used it advantageously in leprosy, ichthyosis, scrofulous enlargements, and constitutional syphilis. He gave the seeds in the dose of six grains three times a day. (*Am. Journ. of Med. Sci.*, N. S. xxx. 493; from *Association Med. Journ.*, Aug. 17, 1855.) W.

HAMAMELIS VIRGINICA. *Witch-hazel.* An indigenous shrub, from five to fifteen feet high, growing in almost all sections of the United States, usually on hills or in stony places, and often on the banks of streams. It is remarkable for the late appearance of its yellow flowers, which expand in September or October, and continue till the weather becomes very cold in winter. The fruit, which is a nut-like capsule not unlike the hazelnut, ripens in the following autumn, and is often mingled on the same plant with the new blossoms. The bark has a bitter, astringent, somewhat sweetish, and pungent taste. It probably first attracted notice as a remedy of the Indians, who are said to have used it as a sedative and discutient in painful tumours, and other cases of external inflammation. It is used in the shape of poultice, or as a wash in the form of decoction, in hemorrhoidal affections and ophthalmia. The leaves are said to possess similar properties, and, in the state of infusion, to be given internally in bowel complaints and hemorrhages. Dr. James Fountain, of Peekskill, N. Y., speaks in strong terms of the efficacy of the bark in hemorrhage of the lungs and stomach, and also highly recommends, as one of the best applications in external piles, an ointment prepared from lard and a decoction of equal parts of this bark, white-oak bark, and that of the apple-tree. He believes the witch-hazel to possess anodyne properties. (*N. Y. Journ. of Med.*, x. 208.) Dr. N. S. Davis agrees with Dr. Fountain in his estimate of this remedy, which he has employed usefully in incipient phthisis. He gives it in decoction, made with an ounce of the bark to a pint of water, of which the dose is a wineglassful every three, six, or eight hours. (*Transact. of Am. Med. Assoc.*, i. 350.) Still another use of the remedy is for the prevention of abortion, for which purpose it is recommended by Dr. W. W. Durham, who states that he has employed it very successfully in obviating the effects of the cotton root in bringing on miscarriage. (*Med. and Surg. Reporter*, Aug. 3, 1867, p. 101; from *Atlanta Med. and Surg. Journ.*) The seeds are black and shining externally, white, oily, and farinaceous within, and edible like the hazelnut. W.

HARTSHORN. *Cornu.* Lond., Ed. This ancient medicine, having been dismissed in the recent revision of the British Pharmacopœia, and not having had a place in our own, requires to be treated of here. It was the horn of *Cervus Elaphus*, the stag or hart, that was directed by the British Colleges. This species of deer inhabits Europe, Asia, and the North of Africa. The horns of our own common deer—*Cervus Virginianus*—though employed in the arts, were not officinal. Hartshorn has been usually imported into this country from Germany, in the form of shavings. These are without smell and taste, pliable, and of an ivory yellow colour. According to M. Merat-Guillot, they contain in 100 parts, 27 of gelatin, 57·5 of phosphate of lime, 1 of carbonate of lime, and 14·5 of water including the loss. Boiling water extracts their gelatin, forming a transparent, colourless jelly, which may be rendered palatable by the addition of sugar, lemon or orange-juice, and a little wine. To prepare it, two pints of water are boiled with four ounces of the shavings to a pint, and the residue strained while hot. The liquid gelatinizes upon cooling. By destructive distillation, the shavings yield an impure solution of carbonate of ammonia, which was formerly called *spirit of hartshorn*; and the same name has been applied to similar ammoniacal solutions from other sources.

Cornu Ustum. (Lond.) *Burnt Hartshorn.* The directions formerly given by the London College for the preparation of this substance were, to "burn pieces of Hartshorn in an open vessel until they are thoroughly white; then powder them, and prepare them in the manner directed for Chalk." The horn must not only be heated, but also burnt, in order that the animal matter may be entirely consumed. The operation may be performed in a common furnace or stove, the air being freely admitted. Care should be taken that the heat be not too great; as otherwise the external surface of the horn may become vitrified, and prevent the complete combustion of the interior portion, while it is itself rendered less fit for use. Burnt hartshorn consists of bone-phosphate of lime, with about 1 per cent. of free lime, derived from the carbonate contained in the horns. Calcined bone is usually sold in the shops for burnt hartshorn. For the chemical characters of bone-phosphate of lime, see *Calcis Phosphas Præcipitata.*

Medical Properties and Uses. The opinion formerly entertained, that burnt hartshorn was antacid, has been abandoned since the discovery of its chemical nature. Its composition suggested its application to the cure of rachitis and mollities ossium, of which the prominent character is a deficiency of phosphate of lime in the bones; and it is said to have been employed in some cases, in connection with phosphate of soda, with apparent success. It is probably, however, inert. The dose is twenty grains or more. The jelly prepared from the shavings of hartshorn has been thought to possess medical virtues; but it is only nutritive and demulcent, and is in no respect superior to calf's-foot jelly. The shavings themselves were formerly used in the preparation of Pulvis Antimonialis. W.

HEDERA HELIX. *Ivy.* This well-known evergreen creeper is a native of Europe. The fresh *leaves* have a balsamic odour, especially when rubbed, and a bitterish, harsh, unpleasant taste. They are used for dressing issues, and, in the form of decoction, have been recommended in sanious ulcers and cutaneous eruptions, particularly tetter and the itch. Dried and powdered, they have been employed in the atrophy of children, and in complaints of the lungs, in the dose of a scruple or more. The *berries*, which have an acidulous, resinous, somewhat pungent taste, are said to be purgative and even emetic. MM. Vandamme and Chevallier discovered in ivy seeds a peculiar alkaline principle, which they called *he-*

derin (*hederia*). It is very bitter, and appears to be closely allied to quinia in febrifuge properties. It is obtained by treating the seeds with hydrate of lime, dissolving the precipitated alkaloid in boiling alcohol, and evaporating the alcoholic solution. (*Am. Journ. of Pharm.*, xiii. 172.) Prof. Posselt has discovered two acids in the seeds, one of which has their taste in a high degree, and was named by him *hederic acid*, the other he did not obtain quite pure. (See *Chem. Gaz.*, March 1, 1849, p. 93.) From the trunks of old ivy plants, growing in the South of Europe and the North of Africa, a resinous substance exudes through incisions in the bark, which has been employed in medicine under the name of *ivy gum*. It is in pieces of various sizes, of a dark yellowish-brown colour, sometimes inclining to orange, more or less transparent, sometimes of a deep ruby-red colour internally, of a vitreous fracture, pulverizable, yielding a lively orange-yellow powder, of a peculiar not disagreeable odour when heated or inflamed, and of a bitterish resinous taste. Its chief constituent is resin, though some pieces contain a considerable proportion of bassorin, and others large quantities of ligneous matter. It was formerly used as a stimulant and emmenagogue, but is now scarcely employed. Placed in the cavities of carious teeth, it is said to relieve toothache. The *wood* of the ivy, which is light and porous, is sometimes used for making *issue-peas*. W.

HELENIUM AUTUMNALE. *False Sunflower. Sneezewort.* An indigenous perennial herb, from three to seven feet high, with large, golden-yellow compound flowers, which appear in August. It grows in all parts of the United States, flourishing best in meadows, moist fields, and other low grounds. All parts of it are bitter and somewhat acrid, and, when snuffed up the nostrils in the state of powder, produce violent sneezing. The leaves and flowers have been recommended as an excellent errhine. Clayton says that the plant is thought to be useful in intermittent fever. W.

HELLEBORUS FŒTIDUS. *Bear's-foot.* This is a perennial European plant, growing in shady places, and flowering in March and April. It derived its specific name from its offensive odour. The leaves, which are the part used, have a bitterish, pungent, and acrid taste, and when chewed excoriate the mouth. The footstalks are still more acrid. Marmé and Husemann have discovered the same active principles in this as in the other species of Helleborus. (See *Part* I., p 450.) This species of hellebore is said by Allioni to be the most acrid and energetic of the plants belonging to the genus. It is powerfully emetic and cathartic, and in very large doses produces dangerous effects. It has long been used in Great Britain as a domestic remedy for worms, and was brought to the notice of the profession by Dr. Bissett, who found it an efficacious anthelmintic, and prescribed it also in asthma, hysteria, and hypochondriasis. M. Decerfs has known it to cause the expulsion of tænia. It is given in powder or decoction. The dose for a child from two to six years old is from five grains to a scruple of the dried leaves, or a fluidounce of the decoction, made by boiling a drachm of the dried leaves in half a pint of water. This quantity should be repeated, morning and night, for two or three days in succession. A syrup made from the juice of the green leaves is used in England. W.

HELONIAS DIOICA. *False Unicorn Plant. Starwort.* This is a small perennial herbaceous plant, growing in most parts of the United States, in shady and hilly situations. The root, which is the part used, is bulbous. Pursh says that it is used as a remedy in colic. Dr. Braman has found it peculiarly efficacious in atony of the generative organs, and has obtained great advantages from it in leucorrhœa. He states the dose of the powdered root at a drachm and a half, three times a day. It may also be given in the forms of syrup and tincture. (*Bost. Med. and Surg. Journ.*, xl. 416.) W.

HERACLEUM LANATUM. (Michaux, *Flor. Boreal. Am.* i. 166.) *Masterwort.* This is one of our largest indigenous umbelliferous plants. It belongs to Pentandria Digynia in the Linnæan system, with the following generic character. "*Fruit*, elliptical, emarginate, compressed, striated, margined. *Corolla* difform, inflexed, emarginate. *Involucre* caducous." (*Willd.*) The root is perennial, sending up annually a hollow pubescent stem, from three to five feet high, and often more than an inch thick. The leaves are ternate, downy beneath, and supported on downy footstalks; the leaflets petiolate, roundish-cordate and lobed. The flowers are white, in large umbels, and followed by orbicular seeds. Like the European species this is sometimes called *cow parsnep*. It grows in meadows and along fences and hedges, from Canada to Pennsylvania, and flowers in June. The root, which is the part used, bears some resemblance to that of common parsley. It has a strong disagreeable odour, and a very acrid taste. Both the leaves and root excite redness and inflammation when applied to the skin. Dr. Bigelow considers the plant poisonous, and advises caution in its use, especially when it is gathered from a damp situation. Masterwort appears to be somewhat stimulant and carminative, and was used successfully by Dr. Orne, of Salem, Massachusetts, in cases of epilepsy, attended with flatulence and gastric disorder. He directed two or three drachms of the pulverized root to be taken daily, for a long time, and a strong infusion of the leaves to be drunk at bedtime. W.

HERMODACTYLS. *Hermodactyli.* Under this name are sold in the shops of Europe the roots or bulbs of an uncertain plant, growing in the countries about the eastern extremity of the Mediterranean. By some botanists the plant is thought to be a *Colchicum*; and *C. variegatum*, a native of the South of Europe and the Levant, is particularly indicated by Fée, Geiger, and others; while by authors no less eminent, the roots are confidently re-

ferred to *Iris tuberosa*. They certainly bear a considerable resemblance to the bulb of Colchicum autumnale, being heart-shaped, channeled on one side, convex on the other, and from half an inch to an inch in length, by nearly as much in breadth. As found in the shops, they are destitute of the outer coat, of a dirty yellowish or brownish colour externally, white and amylaceous within, inodorous and nearly tasteless, though sometimes slightly acrid. They are often worm-eaten. Their chief constituent is starch, and they contain no veratria or colchicia. From this latter circumstance, and from their insipidity, it has been inferred that they are probably not derived from a species of Colchicum; but Geiger observes that they may have lost their acrimony by age. They are in fact almost without action upon the system, and are now seldom used; never, we believe, in this country. It is doubted whether they are the *hermodactyli* of the ancients, which were certainly a powerful medicine, operating very much in the same manner as our colchicum, and like it proving useful in gout and rheumatism. Pereira describes a bitter variety of hermodactyls, which was brought from India by Dr. Royle. The bulbs are smaller and darker than the others, and have externally a striped or reticulated appearance. From their bitter taste they are probably more active. W.

HIBISCUS ABELMOSCHUS. *Abelmoschus moschatus.* Wight and Arnott. An evergreen shrub, growing in Egypt, and in the East and West Indies, and yielding the seeds known under the names of *semen Abelmoschi*, *alceæ Ægyptiacæ*, and *grana moschata*. These are of about the same size as flaxseed, kidney-shaped, striated, of a grayish-brown colour, of an odour like that of musk, and of a warm somewhat spicy taste. They were formerly considered stimulant and antispasmodic; but are now used only in perfumery. The Arabs flavour their coffee with them. They are said to be employed in the adulteration of musk. Another species, *Hibiscus esculentus*, or *Abelmoschus esculentus* of Wight and Arnott, is cultivated under the name of *okra*, *bendee*, or *gombo* in various parts of the world, for the sake of its fruit, which abounds in mucilage, and is used for thickening soup. The leaves are sometimes employed for preparing emollient poultices. The roots, which are a foot or two long, are said also to abound in mucilage, of which they yield twice as much as the althæa root from the same weight, free from any unpleasant odour. Their powder is perfectly white, and superior also to that of the marshmallow. The plant is largely cultivated near Constantinople, where it is much used as a demulcent. (*Am. Journ. of Pharm.*, May, 1860, p. 224.) W.

HIERACIUM VENOSUM. *Rattlesnake Weed.* (*Gray's Manual*, p. 237.) The plants belonging to the genus *Hieracium* are generally called *hawkweed;* but the H. venosum has been distinguished by a special name, derived from its supposed efficiency as an antidote to the bite of the rattlesnake. They are all perennial herbs belonging to the natural family of the Compositæ. The rattlesnake weed has a smooth slender flower-stem, one or two feet high, either naked or furnished with but a single leaf, and dividing at top into a loose spreading corymb of yellow flowers. The plant is common, growing in dry places and open woods, in most of the eastern and northern parts of the United States. The leaves and root are thought to possess medical virtues, and, being deemed astringent, have been used in hemorrhagic diseases. The juice is supposed by some to have the power of removing warts. The medicine may be given in infusion, made in the proportion of two ounces to the pint, of which the dose is a wineglassful. W.

HOG-GUM. GUM-HOGG. Under the latter of these names, a product was sent us from the establishment of J. B. Lippincott & Co., with the information that it filled a somewhat important part in one of the processes connected with the preparation of books. It is in lumps of various sizes, from that of a chestnut to that of a walnut or larger, of an extremely irregular shape, often much contorted, appearing frequently as if consisting of several pieces which had become agglutinated in their soft state, translucent and nearly colourless, with a slight reddish-yellow tint in some pieces, of a rather dull though somewhat shining surface, very hard, brittle with a glassy fracture, inodorous, and nearly or quite tasteless. With water it swells up into a soft transparent mass, which retains this condition long without change, and, if now stirred, instead of forming a consistent mucilage, breaks up into minute, irregular, transparent fragments, which retain this form indefinitely. At our request it was examined chemically by Prof. Procter, who found a small portion of it soluble in water, the remainder swelling up as just stated; and the solution was precipitated by subacetate of lead, showing an analogy with gum, but differing from gum arabic in not giving a precipitate with oxalate of ammonia. Boiling water does not dissolve the jelly formed with it by cold water; but it is dissolved and slightly discoloured by sulphuric acid, and, boiled with diluted sulphuric acid, appears to be changed into soluble gum. The decoction of the jelly, cooled, is not affected with solution of iodine. The insoluble jelly-like portion appears to approach more nearly to bassorin than any other known substance; agreeing with that principle in not forming an adhesive mucilage; and the drug might almost be considered as a sample of *Bassora gum*, but that it differs in shape from any specimens of that gum that we have seen.

Both its geographical and botanical sources are uncertain; but we were informed that it was purchased of the East India importing merchants, and was supposed to be derived from that part of the world From the similarity of name, it would seem probable that it

might be the same substance referred to by Guibourt and other writers under the name of *hog-gum*, or *doctor-gum*, and said to be derived from the Rhus Metopium, of Linnæus, a small tree or shrub growing in the Island of Jamaica. The gum flows from incisions in the bark, and is called a gum-resin by Guibourt, who states that it has a bitter taste. (*Drogues Simples*, 4e ed., iii. 451.) Dr. Griffith, in his *Medical Botany*, ascribes to it emetic properties in large doses. Dr. James Macfadyen, however, in his *Flora of Jamaica* (p. 139), denies this origin of the hog-gum, stating that Sloane had erroneously referred it to *Rhus Metopium*, and had been followed by Brown and others. According to Dr. Macfadyen, the gum is obtained from the *Moronobea coccinea* of Aublet (Guiana, ii. 789, t. 313) by wounding the bark. On hardening after exudation, it is yellow, hard, and friable, somewhat resembling Burgundy pitch. It has a slightly aromatic odour, is insipid, softens under the teeth, and melts in the flame of a candle. It derives the name of hog-gum from the fact that hogs, when wounded, rub themselves against the tree so as to cover the wound with the juice. This product is obviously a resinous substance, and has no resemblance whatever to the gum in question except the similarity in name. Hog-gum is employed in Jamaica, in the form of ointment, mixed with lard, wax, and rosin, and used for the same purposes as Burgundy pitch.

To return to *gum-hogg*, its main use, so far as we know, is to form, in its gelatinous state, a smooth, soft, yet sufficiently firm surface, well adapted to receive and impart colour in the process of marbling paper, for which it is better adapted than any other known product.

After the foregoing account was put into type, we received information which induces us to believe that this drug is really a variety of *Bassora gum*, imported originally from the Gulf of Persia, in the expectation that it might be sold as a substitute for tragacanth. But, having proved on trial wholly unfit for the ordinary purposes of that drug, it was submitted to a chemical examination, in the hope that it might be found applicable to some useful purpose; and this examination having resulted in the discovery of its extraordinary adaptability to the marbling of paper, gave it an unexpected value, which led to a considerable commercial demand. How it happened to receive the name of Gum-hogg, by which it is exclusively known in trade, has not been satisfactorily explained. W.

HURA BRASILIENSIS. *Assacou.* Hura Brasiliensis of Martius, is a Brazilian tree belonging to the family of Euphorbiaceæ, and known to the natives of the country it inhabits by the name of *assacou*. Another species of the same genus, *H. crepitans*, growing in the West Indies, and characterized by the tendency of its fruit to break when ripe with violence into several pieces, and thus scatter the seeds, has long been known as an acrid emeto-cathartic, capable in large doses of acting as a violent poison. The fresh juice the seeds, and a decoction of the bark, all have these properties, which, in fact, belong in a greater or less degree to most of the Euphorbiaceæ; and, as in other members of the same family, an oil expressed from the seeds is actively purgative. It is highly probable that the Hura Brasiliensis is similar in all these respects to its congener. Martius states that the juice is anthelmintic, and employed to intoxicate fish. But attention has recently been especially attracted to the plant, in consequence of reports favourable to its efficacy in that terrible scourge of Brazil, the elephantiasis or leprosy of the country. These reports were received by the Academy of Medicine, of Paris, from the French Consul in one of the towns of Para, of which province the natives are said to regard the remedy as a specific in the complaint referred to. Experiments have been made by the Brazilian physicians, and it is said with favourable results, though complete cures have not been obtained. The fact is that various acrid emeto-cathartic medicines, capable also of producing diaphoresis, have been more or less useful in elephantiasis, as the Calotropis gigantea, and one or more species of Ionidium; and it is probable that the assacou acts in a similar manner, and with similar results. The milky juice of the plant, and an infusion or decoction of the bark are used. The juice is extremely acrid, producing on the skin, when applied to it, an erysipelatous redness and a pustular eruption; and the natives are said to employ it in the preparation of a poison. A grain of the juice made into a pill, or a scruple of the bark infused in a pint of water, is given every day, and gradually increased as the stomach and bowels will bear it. Every week an emetic preparation is administered, made by boiling half an ounce of the bark in a pint of water to half a pint, to which twelve drops of the juice are added. Every second or third day the patient takes a bath, consisting of a saturated infusion of the bark. (*Journ. de Pharm.*, xiv. 424.) W.

HYDRANGEA ARBORESCENS. *Common Hydrangea. Seven Barks.* This species of Hydrangea is indigenous, growing in shady places, in the woods and on the banks of streams throughout the Middle and Southern States. It is a shrub from four to eight feet high, with ovate or cordate leaves, from three to six inches long, generally acuminate, serrately toothed, and slightly pubescent, or nearly glabrous. The flowers are in fastigiate cymes, and appear in July. For a particular botanical description of the plant, the reader is referred to Torrey and Gray's *Flora of North America* (i. 591). The root, which is the part used, consists of a caudex, from which proceed numerous radicles, from the thickness of a quill to that of a finger or more. For use it should be cut into transverse pieces when fresh, and then dried. The taste is aromatic, pungent, and not unpleasant. The root was analyzed by Mr. Laidley, of Richmond, Va., who found in it gum, albumen,

starch, resin, and various salts, among which was a protosalt of iron. (*Am. Journ. of Pharm.*, xxiv. 20.) Attention was first called to it as a remedy in the *New Jersey Med. Reporter* for Oct. 1850 (p. 44), by Dr. S. W. Butler, whose father, Dr. E. Butler, long residing as a missionary among the Cherokee Indians, employed it with great apparent advantage in their calculous complaints. Reports of cases, tending to confirm the opinion of its utility in "sabulous or gravelly deposits" in the urine, have since been published by Drs. W. L. Atlee, D. Horsley, and John C. S. Monkur. (*Ibid.*, Sept. 1854, pp. 393 and 416, Oct. 1854, p. 426, and March, 1855, p. 115.) Dr. Butler used it in the form of decoction, or of a syrup made from the decoction with sugar or honey. A strong syrup may be given in the dose of a teaspoonful three times a day. In overdoses it occasions vertigo, oppression of the chest, &c. W.

HYDRIODIC ETHER *Æther Hydriodicus. Iodide of Ethyl.* This ether may be obtained by gradually and cautiously mixing five parts of alcohol, ten of iodine, and one of phosphorus, and distilling. The residue of the distillation, as ascertained by D. K. Tuttle, is phosphovinic acid. The best mode of proceeding, in order to avoid danger, according to Soubeiran, is to melt the phosphorus with a gentle heat under the alcohol, contained in a wide-mouthed matrass, and to add the iodine gradually through a tube, sealed at the lower end, but perforated at the same end with a number of small holes. The tube is made to pass through a grooved cork, to give exit to the vapours, and is so adjusted as to reach nearly to the surface of the melted phosphorus. The matter in the matrass is distilled to the extent of four-fifths, the distillate is washed with water to separate alcohol, and the decanted ether is dried by the addition of a few pieces of chloride of calcium. Dr. de Vrij recommends the following method for procuring this ether on a large scale. Absolute alcohol is to be saturated with dry muriatic acid gas, the liquid being kept well cooled; and the amount of the acid is to be determined by a sample. The liquid thus saturated is to be put into a retort with as much iodide of potassium as may be necessary to form chloride of potassium; the mixture is to stand for a day; and is then to be submitted to distillation. Finally, the ether which comes over is to be washed and rectified. (See *Am. Jour. of Pharm.*, March, 1859, p. 170.) Hydriodic ether is a colourless non-inflammable liquid, insoluble in water, with a penetrating ethereal odour and pungent taste. Its density is 1·92, and boiling point 158°. Exposed to the air it becomes red from the liberation of iodine, a change which is prevented by adding to the bottle containing it a globule of mercury. Being an iodide of ethyl, its formula is C_4H_5I. M. Huette has proposed this ether as a medicine, to be used by inhalation, placed under a layer of water. Fifteen or twenty inspirations suffice to impregnate the system with iodine. Its physiological effects appear to be those of an antispasmodic and general stimulant. It acts also as a powerful anæsthetic, when sufficiently long inhaled. It increases the appetite, renders the pulse fuller, and gives vivacity to the feelings and activity to the intellect. M. Huette considers it a suitable preparation for bringing the system rapidly under the influence of iodine, and by any desired dose. (See *Am. Journ. of Pharm.*, xxiii. 156.) Since the therapeutic trials of M. Huette were made, Mr. James Turnbull, of Liverpool, and Dr. Henry Fisher, of New York, have used this ether by inhalation in chronic pulmonary diseases with satisfactory results. Dr. Fisher specifies chronic bronchitis and phthisis as the diseases in which he has found it useful. The dose is 15 drops, three or four times a day, inhaled from a handkerchief. Hydriodic ether often has an unpleasant smell from the presence of foreign substances, which render it offensive to patients. Phosphorus is a common and injurious impurity. B.

HYDROCOTYLE ASIATICA. *Thick-leaved Pennywort. Bevilacqua.* Boileau. This is a small umbelliferous plant, with a trailing stem, and, from the shape of its leaves, bearing some resemblance to the violet. It grows in moist grounds in India, Southern Africa, and the islands of the Indian Ocean. It has long been ranked among the medicinal plants of India, where it has been used as an alterative to purify the blood. An elaborate analysis has been made of it by M. Jules Lépine, who discovered in it a peculiar oleaginous substance which he calls *vellarine*, and in which he supposes the active properties to reside. It has a strong odour recalling that of the plant, and a bitter, pungent, and persistent taste. (*Journ. de Pharm.*, Juillet, 1855, p. 49.)

The plant has been supposed to possess diuretic properties; and, according to Ainslie, is employed in infusion with fenugreek in fever and bowel complaints. But it has recently attracted attention, from the claims strongly urged in its favour as a remedy in that most obstinate affection often called leprosy, but more correctly elephantiasis of the Greeks. It was first employed in this complaint by Dr. Boileau, of the Island of Mauritius, who was himself a victim of the disease, and had resorted to this remedy under the false impression that it might be identical or analogous with the *cuichunchulli*. He was so much pleased with its effects that he was induced to try it upon others; and a great many lepers were put under its influence. All the cases were arrested, many were benefited, and in some the disease almost disappeared. The statements of Dr. Boileau have been supported by those of M. Lépine, of Pondicherry, and the medicine would certainly seem to merit a thorough investigation. Dr. Boileau, probably at first in ignorance of its botanical title, gave it the name of *bevilacqua*. He used it in powder, infusion, and syrup. An ounce of the dried plant may be given daily, in the form of infusion made with a pint of water. This should

be continued for several weeks, combined with baths, and attention to the state of the bowels. After this preparation, the syrup is to be given in spoonful doses three times a day, to be gradually increased after three weeks, if no improvement has taken place, to eight spoonfuls daily. The powder may be added to the syrup, if deemed necessary, in the dose at first of fifteen grains, to be increased cautiously to a drachm. (*Journ. de Pharm.*, 3e sér., xxiv. 424, and xxv. 153.) This account of the remedy has been in some measure confirmed by the testimony of Mr. E. J. Waring, *of the Madras Medical Service*, and Dr. Hunter, who have found it especially useful in secondary syphilis and scrofulous ulcers. (*Pharm. Journ.*, Aug. 1860, p. 143.) M. Lecocq, however, has been led by his experience and observation to the conclusion, that no sufficient evidence exists of any case of leprosy cured by this remedy, and that it is equally inefficient in other skin diseases. (*Ann. de Thérap.*, 1859, p. 79.) W.

HYDROCYANIC ETHER. *Æther Hydrocyanicus. Hydrocyanate of Ethylen. Cyanide of Ethyl. Cyanuret of Ethyl.* This ether was discovered by Pelouze. It is formed by distilling a mixture of sulphovinate of baryta and cyanide of potassium. It is a colourless liquid, of a penetrating garlicky odour, soluble in alcohol and ether, sparingly soluble in water, boiling at 180°, and weighing specifically 0·78. It is very poisonous, but less so than hydrocyanic acid, with which it agrees in therapeutic action and dose. B.

HYDROSULPHATE OF AMMONIA, SOLUTION OF. AMMONIÆ HYDROSULPHURETUM. *Dub. Solution of Sulphide of Ammonium.* Br. Appendix. This former officinal of the Dublin Pharmacopœia was prepared in the following manner. "Take of Solution of Ammonia *four fluidounces* [Imperial measure]; Sulphuret of Iron *one ounce and a half* [avoirdupois]; Oil of Vitriol of Commerce *one fluidounce and a half* [Imp. meas.]; Water *fifteen ounces* [avoird.]; Distilled Water *two ounces* [avoird.]. Place the Sulphuret of Iron and Water in a two-necked bottle, and, adding the Oil of Vitriol by degrees through a safety funnel, conduct by suitable tubes the sulphuretted hydrogen which is disengaged, first through the Distilled Water placed in a small intermediate vial, and then to the bottom of a bottle containing the Ammonia, the neck of the latter, through which the glass tube conveying the gas passes, being loosely plugged with tow. If, when the development of gas has ceased, a drop of the ammoniacal liquid, added to a saturated solution of sulphate of magnesia, gives no precipitate, the preparation is completed; but, should a precipitate occur, the hydrosulphuret still contains free ammonia, and must, therefore, be again subjected to the action of a stream of sulphuretted hydrogen. The Hydrosulphuret of Ammonia must be kept in a green glass bottle, furnished with an accurately ground stopper. The specific gravity of this solution is 0·999" (*Dub.*) This preparation is a solution of bihydrosulphate of ammonia in water, and is formed by passing a stream of hydrosulphuric acid gas (sulphuretted hydrogen) through water of ammonia, contained in a Woulfe's bottle. Considered as a byhydrosulphate, its formula is $NH_3.2HS$; but it is probably a sulphosalt, with the formula NH_4S,HS, and was so considered in the original British Pharmacopœia, where it held a place among the test solutions in the Appendix. In the present Pharmacopœia it is called sulphide of ammonium, without a formula. The hydrosulphuric acid is obtained by acting with dilute sulphuric acid on sulphuret of iron. The water yields its oxygen to the iron forming protoxide of iron, with which the sulphuric acid combines; while the hydrogen of the water, uniting with the sulphur, generates hydrosulphuric acid.

Mr. Spence proposes a cheap method of preparing hydrosulphate of ammonia, should this ever come largely into demand. It consists simply in passing vapour through a mixture of sulphate or muriate of ammonia with twice its weight of oxysulphate of calcium, or the refuse lime of the process for purifying gas, and to receive the volatile product in an apparatus for condensation. The result is hydrosulphate of ammonia, or sulphuret of ammonium. The author of this plan has had the opportunity of learning that the vapours of this salt are highly noxious; a workman having become asphyxiated by them, and been recalled to life with great difficulty. (*Journ. de Pharm.*, Juillet, 1867, p. 73; from *Polytec. Journ.*, clxxiii. 308.)

Hydrosulphuret of ammonia is a liquid of a greenish-yellow colour, very fetid smell, and acrid, disagreeable taste. It is characterized by giving coloured precipitates with neutral metallic solutions, for which it is much used as a test. It is decomposed by acids, which cause the escape of hydrosulphuric acid with effervescence, and the deposition of sulphur. This preparation is sedative, lessening the action of the heart in a remarkable degree, and producing, when given in large doses, nausea, vomiting, vertigo, and drowsiness. It was proposed as a remedy in diabetes mellitus, by Dr. Cruickshank, for the purpose of lessening the morbid appetite in that disease, and has been employed by Dr. Rollo and others. The dose is five or six drops in a tumblerful of water three or four times a day, to be gradually increased until giddiness is produced. B.

HYPERICUM PERFORATUM. *St. John's Wort.* A perennial herb, abundant both in Europe and this country, often covering whole fields, and proving extremely troublesome to farmers. It is usually from one to two feet high, with leaves which, from the presence of numerous transparent vesicles, appear as if perforated, and have hence given origin to the botanical designation of the plant. The flowers, which are numerous and of a deep-yellow colour, appear during the summer from June to August. The flowering

summits are the parts used, though the unripe capsules are possessed of the virtues of the plant in an equal degree, and the seeds are said to be even stronger. St. John's wort has a peculiar balsamic odour, which is rendered more sensible by rubbing or bruising the plant. Its taste is bitter, resinous, and somewhat astringent. It imparts a yellow colour to cold water, and reddens alcohol and the fixed oils. Its chief constituents are volatile oil, a resinous substance, tannin, and colouring matter. As a medicine it was in high repute among the ancients, and the earlier modern physicians. Among the complaints for which it was used were hysteria, mania, intermittent fever, dysentery, gravel, hemorrhages, pectoral complaints, worms, and jaundice; but it was, perhaps, most highly esteemed as a remedy in wounds and bruises, for which it was employed both internally and externally. It is difficult to ascertain its exact value as a remedy; but, from its sensible properties, and from the character of the complaints in which it has been thought useful, it may be considered, independently of its astringency, as somewhat analogous in medical power to the turpentines. It formerly enjoyed great reputation for the cure of demoniacs; and the superstition still lingers among the vulgar in some countries. At present the plant is scarcely used except as a domestic remedy. The summits were given in the dose of two drachms or more. A preparation was at one time officinal, under the name of *oleum hyperici*, made by treating them with a fixed oil. It has a red colour, and is still used in many families as a sovereign remedy for bruises. It is commonly called *red oil*. W.

HYPOPHOSPHITES. Attention has been called to these salts, in consequence of their recommendation by Dr. Churchill, of Paris, in the treatment of phthisis, in which they are thought to be useful by furnishing phosphorus to the tissues. A paper on their mode of preparation and qualities was communicated by Prof. Procter to the *American Journal of Pharmacy* (March, 1858, p. 118), to which we are indebted for much of what follows on the chemistry of the subject. Hypophosphorous acid consists of one eq. of phosphorus and one of oxygen, and always contains two or three eqs. of water. It has a strong affinity for oxygen, and acts therefore as a powerful deoxidizing agent, and carries this property as well as water with it into composition. When heated it is resolved into phosphuretted hydrogen and phosphoric acid. Its salts are generally soluble in water and deliquescent, and many of them are soluble in alcohol. They are converted into phosphates by heat, with the escape of phosphuretted hydrogen; and some of them are explosive.

Hypophosphite of lime has attracted most attention, and would meet the views of those who wish to supply phosphate of lime to the system, as the hypophosphorous acid is converted into the phosphoric by its deoxidizing power. To prepare it Prof. Procter gives the following formula. Slake 4 lbs. avoird. of lime with a gallon of water, add it, in a deep boiler, to 4 gallons of boiling water, and mix thoroughly. To the mixture add a pound avoird. of phosphorus, and continue the boiling, adding hot water from time to time to keep up the measure, until the combination is complete, and phosphuretted hydrogen is no longer evolved. It is necessary that provision should be made for the escape of the gas, which takes fire spontaneously in contact with the air. There are formed in the liquid phosphate and hypophosphite of lime, the phosphorus having become oxidized at the expense of the water, the hydrogen of which has escaped in combination with another portion of phosphorus, which is therefore lost. The liquid is filtered to separate the insoluble phosphate and residuary lime, then concentrated, and refiltered to separate the carbonate of lime formed by the action of the air on a little lime held in solution, and lastly evaporated till a pellicle appears; after which the salt may be allowed to crystallize by setting the liquid aside, or may be obtained in the granular form by continuing the heat, and stirring. The salt should be introduced into bottles. It is white, of a somewhat pearly lustre, and crystallizes in flattened prisms. It is soluble in 6 parts of cold water, little more so in boiling water, and slightly soluble in diluted, but insoluble in officinal alcohol. Its formula is CaO,2HO,PO.

Hypophosphite of soda is prepared by mixing solutions of hypophosphite of lime and crystallized carbonate of soda, in the proportion of 6 ounces of the former dissolved in 4 pints of water, to 10 of the latter in one and a half pints. Double decomposition takes place, with the formation of carbonate of lime and hypophosphite of soda, of which the latter is held in solution, and the former precipitated. After filtration to separate the carbonate of lime, the solution is evaporated to a pellicle, and then stirred constantly till the salt granulates, the heat being continued. If required quite pure, the granulated salt is dissolved in officinal alcohol; and the liquid, having been evaporated to a syrupy consistence, is set aside to crystallize. Sometimes the hypophosphite of soda explodes with violence during the evaporation of its solution. This was ascribed to the use of too high a heat; but the same accident has occurred when the heat was applied by means of a water-bath. (See *Am. Journ. of Pharm.*, Jan. 1850, p. 87.) In a communication of Mr. Tuson to the *Chemical News* (No. 31, p. 46), it is stated that, though he had superintended the manufacture of large quantities of the hypophosphites of lime and of soda, he had never witnessed anything like an explosion; but the heat employed in evaporation had never approached 212°; and this is probably the true explanation. Caution, therefore, should be observed to evaporate at a low temperature. Hypophosphite of soda crystallizes in rectangular tables of a pearly lustre, deliquesces on exposure, and is soluble both in water and alcohol. Its formula is NaO,2HO,PO.

Hypophosphite of potassa is prepared in the same manner as the salt of soda; 5 75 ounces of granulated carbonate of potassa, dissolved in half a pint of water, being substituted for the carbonate of soda. This salt is still more deliquescent than the preceding, and therefore less eligible. Its formula is KO,2HO,PO.

Hypophosphite of ammonia may be obtained in like manner from hypophosphite of lime and sulphate or sesquicarbonate of ammonia; and the *hypophosphite of sesquioxide of iron* from solution of hypophosphite of soda or ammonia with solution of sulphate of sesquioxide of iron. A *hypophosphite of quinia* has also been proposed. (*Chem. Gaz.*, No. 43, p. 186.) Prof. Procter gives a formula for preparing *hypophosphorous acid*, consisting in the decomposition of hypophosphite of lime in solution by oxalic acid, which precipitates the lime, leaving the hypophosphorous acid in solution. The quantities are so proportioned that a fluidrachm shall contain 6 grains of the acid, equivalent to about 2·25 grains of phosphorus. The dose of the acid is therefore from ten minims to a fluidrachm.

As the soluble salts of mercury and silver are reduced by the hypophosphites, they are of course incompatible with it in prescriptions. With the hypophosphite of lime, all the soluble sulphates and carbonates produce precipitates. The hypophosphite of iron may be given with the preparations of cinchona, as, though blackened by the tannic acid of galls, it is not so by cincho-tannic acid. As these salts are insoluble in cod-liver oil, they should be dissolved in syrup before being added to the oil. Prof. Procter prepares a *syrup of hypophosphite of lime* by dissolving a troyounce of the salt in 9·5 fluidounces of water, then adding 12 troyounces of sugar and dissolving with a gentle heat, and finally adding half a fluidounce of the fluid extract of vanilla. The dose of the syrup is from one to four fluidrachms, three times a day. A compound syrup is prepared by the same writer, containing the hypophosphites of lime, soda, potassa, and iron, with hypophosphorous acid, a formula for which will be found in the same communication to which reference has been made above.

The author does not wish to be understood as recommending these remedies in consumption. The weight of testimony appears to him to be opposed to the first favourable impressions; and, though some cases may have seemed to be benefited, yet great care must be taken not to allow a reliance on the hypophosphites to interfere with the use of remedies known to be efficient, as cod-liver oil and supporting measures generally. But though of doubtful efficacy in phthisis, the hypophosphites may be valuable remedies in other affections, and would seem to be indicated in cases in which there may be defect of nutrition of the nerve centres, of which phosphorus forms an important constituent; and Dr. J. D. Brown, of the Albany City Hospital, has found them highly useful in diseases attended with the loss of nerve power, and in many of the complaints of infancy connected with the scrofulous diathesis, and defect in the osseous system. (*Boston Med. & Surg. Journ.*, lxxiii. 412, Dec. 21, 1865.) The dose of either of the hypophosphites may be from ten to thirty grains, three times a day. W.

HYPOSULPHITE OF LIME. *Calcis Hyposulphis.* Under the head of *Sodæ Hyposulphis*, page 822, reference is made to hyposulphite of lime, as possessing, with other hyposulphites, useful properties in the destruction of the lower forms of animal and vegetable life, by which the human system is often seriously infested; and the hope is even indulged that it may become a most useful agent in the prevention and relief of a class of diseases depending on infection of the blood. The following mode of preparing it is recommended by M. J. Laneau, of Paris. Take 1000 parts of sulphur, 400 of lime, and 4000 of rain-water; slake the lime with sufficient of the water, add the sulphur and the residue of the water, and boil for an hour and a half, adding water to keep up the measure; when cool filter the liquid through linen covered with filtering paper; and wash the residue with 1000 parts of water. A solution is thus obtained of polysulphuret of calcium of the sp. gr. 1·141. Into this pass a current of washed sulphurous acid gas until the solution becomes colourless; separate the sulphur precipitated (which may be used for the officinal *Precipitated Sulphur*); and evaporate the clear solution at a heat not exceeding 140° F., until it begins to crystallize, when it is to be set aside. The product is 700 parts of hyposulphite of lime. This is in six-sided crystals, which effloresce in a dry air. M. Laneau prepares a syrup of the hyposulphite by dissolving 10 parts of the crystallized salt in 20 parts of distilled water, and mixing with the solution 170 parts of syrup of orange flowers. (See *Am. Journ. of Pharm.*, May, 1863, p. 223.) The dose of the salt is from ten to twenty grains three times a day, of the syrup from two to four fluidrachms.

Of the *hyposulphites*, generally, it may be said that they closely resemble the sulphites in medical properties, and may be employed as substitutes for those salts, over which they have the advantage of greater stability, passing less readily into sulphates on contact with the air. They may be prepared by boiling a sulphite or bisulphite for some time with sulphur. They are very soluble in water, and are recognised by the precipitation of sulphur when decomposed by an acid. W.

HYPOSULPHITE OF SODA AND SILVER. *Sodæ et Argenti Hyposulphis.* This double salt may be prepared by dissolving freshly precipitated oxide of silver in a solution of hyposulphite of soda, and evaporating the solution. It is in the form of minute crystals, very soluble in water, but insoluble in alcohol, and possessing a very sweet taste.

Its solution, protected from the light, undergoes no change, and, when quite pure, does not discolour the skin or linen. M. Delioux, of Rochefort, has tried this salt externally only, and thinks it acts like nitrate of silver, but more mildly. He used it with advantage, especially in urethral discharges, dissolved in the proportion of one or two parts in two hundred of water. (*B. and F. Medico-chir. Rev.*, Am. ed., April, 1853, p. 447; from the *Bulletin de Thérap.*) B.

HYRACEUM. Under this name, a substance from the Cape of Good Hope has been introduced to the notice of the profession, in Europe, as a substitute for castor. It is the product of *Hyrax Capensis*, an animal of South Africa, about the size of a large rabbit. It is said to be collected in small pieces on the rugged sides of mountains, and is probably the excrement of the animal. It is rather hard, tenacious, of a blackish-brown colour, and in taste and smell not unlike castor. It is inflammable, and yields portions of its constituents to water and alcohol. Examined with the microscope, it has been found to contain vegetable tissues, animal hair, sand, and globular particles, either resinous or oily. Schrader has found it to contain stearin, a gum-resin soluble in absolute alcohol, an odorous yellow substance soluble in ordinary alcohol and in water, a brown substance soluble in water, and insoluble residue. Dr. Pereira, from whose paper the above account is extracted, considered it worthless as a therapeutical agent, though in physiological effects it is said exactly to resemble American castor. (*Pharm. Journ.*, x. 123.) For an elaborate paper on this substance by M. J. Léon Soubeiran, see *Journ. de Pharm.* (xxix. 378). W.

HYSSOPUS OFFICINALIS. *Hyssop.* This is a labiate plant, belonging to the class and order Didynamia Gymnospermia of the sexual system. It is perennial, with numerous erect, quadrangular, somewhat branching stems, which are woody in their interior portion, about two feet high, and furnished with opposite, sessile, lanceolate-linear, pointed, punctate leaves. The flowers are violet-coloured or blue, sometimes white, turned chiefly to one side, and arranged in half verticillated, terminal leafy spikes. The upper lip of the corolla is roundish and notched at the apex, the lower is divided into three segments, of which the undermost is obovate.

Common hyssop is a native of Europe, where, as well as in this country, it is cultivated in gardens. The flowering summits and leaves are the parts used. They have an agreeable aromatic odour, and a warm, pungent, bitterish taste. These properties they owe to an essential oil, which may be separated by distillation with water, and rises also with alcohol. Hyssop is a warm, gently stimulant aromatic, applicable to the same cases as the other labiate plants. Its infusion has been much employed in chronic catarrhs, especially in old people, and those of a debilitated habit of body. It acts by facilitating the expectoration of mucus when too abundantly secreted. In this country, however, it is seldom used by regular practitioners. W.

IBERIS AMARA. *Bitter Candytuft.* A small herbaceous plant, indigenous in Europe, where it is cultivated in gardens on account of its bright milk-white flowers. The leaves, stem, and root are said to possess medicinal properties; but the seeds are the most efficacious. The plant appears to have been employed by the ancients in rheumatism, gout, and other diseases. It was again brought into notice by Dr. Silvester, who ascribed to the late Dr. Williams, of St. Thomas's Hospital, London, the merit of having first ascertained its real therapeutic value. In large doses it produces giddiness, nausea, and diarrhœa; but its virtues do not seem to be associated with any perceptible physiological effect. It is thought to exercise a happy influence over the excited actions of the heart, and is especially useful in hypertrophy. Much advantage is also said to have accrued from it in asthma, bronchitis, and dropsy. The dose of the seeds is from one to three grains. (*Prov. Med. and Surg. Journ.*, July 28, 1847.) W.

ILEX. *Holly.* Several species of Ilex are employed in different parts of the world. The *I. Aquifolium*, or *common European Holly*, has attracted much attention in France. It is usually a shrub, but in some places attains the magnitude of a middling-sized tree. Different parts of it are used. The viscid substance called birdlime is prepared from the *inner bark*. The *leaves*, which are of a bitter, somewhat austere taste, were formerly much esteemed as a diaphoretic, and in the form of infusion were employed in catarrh, pleurisy, smallpox, gout, &c. A few years since they gained some reputation in France as a cure for intermittents, and were considered by some as equal to Peruvian bark; but the first reports in their favour have not been fully confirmed. They were used in powder, in the dose of a drachm two hours before the paroxysm; and this dose was sometimes repeated frequently during the apyrexia. Their febrifuge virtues are said to depend on a bitter principle, for which the name of *ilicin* has been proposed. M. Labourdais obtained this principle by boiling a filtered decoction of holly leaves with animal charcoal, allowing the charcoal to subside, washing it, then treating it with alcohol, filtering off the alcoholic solution, and evaporating it to a syrupy consistence. The liquid thus obtained was very bitter, and, on being allowed to evaporate spontaneously, yielded an amorphous substance, having the appearance of gelatin, which was the principle in question. (See *Am. Journ. of Pharm.*, xxi. 89.) A yellow colouring substance called *ilexanthin* and a peculiar acid, called *ilicic acid*, have been obtained by Dr. F. Moldenhauer. Ilexanthin is obtained in the following man-

ner. The leaves are exhausted with alcohol, the alcohol is distilled off, and the residue set aside for several days. A sediment forms, which is separated from the mother-liquor, treated with ether to remove the chlorophyll, and then purified by repeated solution in alcohol and crystallization. The composition of Ilexanthin is $C_{34}H_{22}O_{22}$. It crystallizes in yellow needles, which change colour at 365° F., melt at 388°, and at 417° boil with decomposition, and are not sublimable. It is insoluble in ether, but soluble in alcohol. In cold water it is almost insoluble; but hot water dissolves it freely, and deposits it in crystals on cooling. (*Chem. Cent. Blat.*, Oct. 21, 1857, p. 766.) The *berries* are about the size of a pea, red and bitter, and are said to be purgative, emetic, and diuretic. Ten or twelve of them will usually act on the bowels, and sometimes vomit. Their expressed juice has been used in jaundice.

The *Ilex opaca*, or *American holly*, is a middling-sized evergreen tree, growing throughout the Atlantic section of the United States, and especially abundant in New Jersey. It is so similar to the European plant, that it is, by some writers, considered as the same species. The berries, examined by Mr. D. P. Pancoast, were found to contain tannin, pectin, two crystallizable organic principles, and salts of potassa, lime, and magnesia. One of the crystallizable principles was inodorous and tasteless, the other inodorous but intensely bitter. The latter was obtained by a treatment similar to that of M. Labourdais, above described; but, after the evaporation of the tincture to a syrupy consistence, the process was continued by adding carbonate of potassa and afterwards ether, and agitating briskly. The ethereal solution, rising to the surface on repose, was separated, and allowed to evaporate spontaneously. Crystals of the bitter principle were deposited. This is probably pure *ilicin*. (*Am. Journ. of Pharm.*, xxviii. 314.) This species is said to possess the same medical properties as *I. Aquifolium*.

Ilex Paraguaiensis, the *I. Mate* of St. Hilaire, yields the celebrated *Paraguay tea*, so extensively consumed as a beverage in the interior of South America. It is a small tree or shrub growing wild along the streams in Paraguay, and also cultivated for the sake of its leaves, which are the part used. These are stripped from each plant every two or three years. (Parodi, *Revista Farmaceutica de Buenos Aires*, Jan. 1861.) The period of their collection extends from December to August, sometimes beginning earlier but never continuing later. Companies are formed who penetrate far into the forest at a distance from the settlements, and devote a long time to the collection and preparation of the leaves These are first dried by exposure to heat, and are then reduced to powder more or less fine, which is kept for several months protected from moisture, and then packed in sacks, and delivered to commerce. (A. Demersay, *Ann. de Thérap.*, 1868, p. 72.) They have a balsamic odour and bitter taste, and are usually at first disagreeable to the palate. They have a pleasant and corroborant effect upon the stomach; but, when very largely taken are said to purge and vomit. They are used in the form of infusion. According to Stenhouse, these leaves contain a principle identical with the caffein of tea and coffee; and like them contain also tannic acid; so that a close analogy exists in composition as well as effects between these three products, so little allied botanically, and so far separated in place of growth. The leaves have, within two or three years, been analyzed by D. A. Strauch, with the following results; 0·450 of theïn, 20·880 of caffeotannic acid, 2·830 of gum, 5·902 of resin, chlorophyll, and wax, 1·200 of starch, 9·361 of protein compounds, 22·148 of cellulose, 8·640 of apotheme, 3·896 of salts, 8·100 of water, with a trace of volatile oil, and some sand and extractive. (*Am. Journ. of Pharm.*, July, 1868, p. 314; from *Wittstein's Vierteljahr.*, A. D. 1867, pp. 167–182.)

The *Ilex vomitoria* of Aiton and Linn., the *I. Cassina* of Michaux, is a handsome evergreen shrub, growing in our Southern States, and especially abundant along the southern coast of Florida. It is the *cassina* of the Indians, who formerly employed a decoction made from the toasted leaves, called *black drink*, both as a medicine, and as a drink of etiquette at their councils. It acts as an emetic. The leaves of the *Ilex Dahoon* of Walter and Michaux have similar properties, and are also said to have entered into the composition of the black drink. W.

ILLICIUM FLORIDANUM. *Florida Anise-tree.* This is an evergreen shrub or small tree, growing in Florida, along the coast which bounds the Gulf of Mexico The bark, leaves, and probably also the seed-vessels, are endowed with a spicy odour and taste, analogous to those of anise, and might, perhaps, be used for the same purpose as that aromatic. It is a question worthy of investigation, whether the capsules of this plant might not be substituted for those of the *Illicium anisatum* or *star aniseed*, which yield much of the oil used in this country under the name of *oil of anise*. (See *Anisum*.) Another species, *I. parviflorum*, a shrub found by Michaux in the hilly regions of Georgia and Carolina, has a flavour closely resembling that of sassafras root. W.

IMPATIENS FULVA AND IMPATIENS PALLIDA. *Touch-me-not. Jewel-weed. Balsam-weed.* These two species of Impatiens are indigenous, annual, succulent plants, from two to four feet high, growing in low moist grounds in all parts of the Union, and flowering in July and August. They may be known by their tender, juicy, almost transparent stems; by their yellow flowers, which in one species are pale and sparingly punctate, in the other, are deeper coloured and crowded with dark spots; and by their capsules, which burst elastically, and curl up with the slightest pressure. They probably pos-

sess properties similar to those of the *I. Noli-me-tangere* of Europe, which has an acrid burning taste, and, when taken internally, acts as an emetic, cathartic, and diuretic, though considered dangerous, and therefore little used. The late Dr. Ruan, of Philadelphia, informed us that he had employed with great advantage, in piles, an ointment made by boiling the American plants, in their recent state, in lard. The flowers may be used for dyeing yellow. The *I. Balsamina* or *balsam-weed, touch-me-not, &c.* of the gardens, resembles the other species in its effects. W.

IMPERATORIA OSTRUTHIUM. *Masterwort.* An umbelliferous plant indigenous in the South of Europe. The root has a strong odour, similar to that of angelica, and a pungent, biting, aromatic taste, attended with a flow of saliva, and followed by a glowing warmth which remains long in the mouth. A crystallizable, tasteless principle, called *imperatorin*, was extracted from the root by Wackenroder, by allowing the ethereal tincture to evaporate, and recrystallizing the residue from ether and alcohol. It was purified by combining it with lime, and decomposing the lime compound by acetic acid. R. Wagner has ascertained that this principle is identical with *peucedanin*, obtained from the root of *Peucedanum officinale*, which was formerly employed in medicine, but is now quite out of use. The principle is composed of carbon, hydrogen, and oxygen, and is probably inert. (*Chem. Gaz.*, Nov. 1, 1854.) The root of masterwort was formerly considered alexipharmic, stomachic, corroborant, emmenagogue, diuretic, and diaphoretic; and was used in a wide circle of complaints with so much supposed success as to have gained for it the title of *divinum remedium*. The fact, however, appears to be, that it is merely a stimulant aromatic, analogous but inferior to angelica, which has nearly superseded it in European practice. In this country it is unknown as a remedy, and its vulgar name has been applied to another plant. W.

INDELIBLE INK. This is prepared by dissolving two drachms of nitrate of silver and a drachm of gum arabic in a fluidounce of distilled water, coloured with a little Indian ink. It is used for writing with a pen on linen and muslin. The place to be marked is prepared by being moistened with a solution of two ounces of crystallized carbonate of soda and two drachms of gum arabic in four fluidounces of water, and then dried. The alkaline solution decomposes the nitrate, and protects the cloth from the action of the free nitric acid. At the end of 24 hours the spot is to be washed.

Mr. Redwood, of London, proposes the following indelible ink, not requiring the use of a mordant. Dissolve an ounce of nitrate of silver, and an ounce and a half of crystallized carbonate of soda, separately, in distilled water, and mix the solutions. Wash the precipitated carbonate of silver, and, having introduced it, still moist, into a Wedgwood mortar, rub it with eight scruples of tartaric acid, until effervescence ceases. Then add strong solution of ammonia, just sufficient to dissolve the tartrate of silver formed (about two fluidounces). Lastly, having mixed in half a fluidounce of archil, half an ounce of white sugar, and an ounce and a half of powdered gum arabic, add sufficient distilled water to make the whole measure six fluidounces. M. Soubeiran has given the following formula for indelible ink, which he considers simpler than Mr. Redwood's. Dissolve 8 parts of crystallized nitrate of silver, 3 of nitrate of copper, and 4 of carbonate of soda, in 100 of water of ammonia, and add to the solution a little gum. The marks, produced by nitrate of silver on linen or muslin, may be completely removed by moistening them with a solution of corrosive sublimate in 30 parts of distilled water, and afterwards washing them with ordinary water.

M. Jules Guiller has devised the three following formulas for marking-inks for linen. 1. Nitrate of silver 11 parts; distilled water 85; powdered gum arabic 20; carbonate of soda 22; solution of ammonia 20. Dissolve the carbonate of soda in the water, rubbing the solution with the gum, and the nitrate of silver in the ammonia. Mix the solutions, and gradually heat the mixture in a flask until it boils. This ink flows readily from a pen. 2. Nitrate of silver 5 parts; distilled water 12; powdered gum arabic 5; carbonate of soda 7; solution of ammonia 10. The ingredients are treated as in the preceding formula, with the exception that the mixed solution is heated until it becomes of a very dark colour, and is reduced about one-twentieth in volume by evaporation. This ink is suitable for marking on linen with stamps. 3. Nitrate of silver 17 parts; distilled water 85; powdered gum arabic 20; carbonate of soda 22; solution of ammonia 42; sulphate of copper 33. Dissolve the nitrate of silver in the ammonia, the carbonate of soda in 25 parts of the water, and the gum in the remaining 60. Then mix with the soda solution, first the gum solution, and afterwards the silver solution. Lastly, add the sulphate of copper. This ink has a blue, instead of the dark-brown colour of the others. (See *Am. Journ. of Pharm.*, Jan. 1853, p. 33.)

Herberger recommends the following indelible ink for other purposes than marking linen. Dissolve wheat gluten, carefully freed from starch, in a little weak acetic acid, and dilute the solution with rain-water, so as to have about the strength of wine vinegar. For every four ounces of the solution, add ten grains of the best lampblack, two grains of indigo, and a little oil of cloves. This ink has a beautiful black colour, and cannot be removed by chlorine or dilute acids. (*Chem. Gaz.*, No. 70, p. 394.) B.

INDIAN RED. A purplish-red pigment, brought from the island of Ormus in the Persian Gulf. It is a *red ochre*, and owes its colour to the red oxide of iron. W.

INDIAN YELLOW. This is a pigment manufactured from a yellow substance from India, called *purree*. Purree occurs in commerce in balls, of from three to four ounces in weight, which are dark-brown externally, and deep-orange within. It has a peculiar smell, closely resembling that of castor. This circumstance gave rise to the belief that it was of animal origin; but Dr. Stenhouse, who examined it chemically, finds that it contains no nitrogen, and from this and other facts is led to the opinion that it is a vegetable substance. Upon analysis he found it to consist of magnesia, united with a peculiar acid, which he names purreic (*euxanthic acid* of Erdmann), and which forms nearly one-half of the crude substance. *Purreic acid* is in small crystals of a light yellow colour dissolving sparingly in cold water, pretty readily in boiling water, and abundantly in hot alcohol. It has at first a sweetish and then a slightly bitter taste, and possesses, in appearance, considerable resemblance to berberina. When acted upon by boiling nitric acid, it is finally converted into a new acid, crytallizing in yellow needles, called by Erdmann, *oxypieric acid*. Purreic acid has the formula $C_{40}H_{16}O_{21}$. From his examination of purree, Dr. Stenhouse concludes that it is probably the juice of some plant, saturated with magnesia, and boiled down to a solid consistence. (See his paper in the *Philos. Mag.*, xxv. 321.) Other authorities conjecture that it is obtained from the deposit of camels' urine, after the animals have eaten the fruit of *Mangostana mangifer*. (*Chem. Gaz.*, April, 1855, p. 134.) B.

INDIGO. This well-known and highly important dye-stuff is obtained from various species of *Indigofera*, especially *I. tinctoria*, *I. Anil*, and *I. argentea*; and is said to be afforded also by other plants, such as *Wrightia tinctoria*, *Polygonum tinctorium*, *Galega tinctoria*, &c. It does not exist ready formed, but is generated, during fermentation, from another principle existing in the plant. This principle appears to have been isolated from Isatis tinctoria by Ed. Schunck, who has named it *indican*. Through the agency of the mineral acids, it is resolved into indigo and sugar; and perhaps the same result may take place in fermentation. Indican is yellow, amorphous, of a nauseous bitter taste, with an acid reaction, and readily soluble in water, alcohol, and ether. It contains nitrogen. (*Pharm. Journ.*, xv. 166.) In the process of preparing indigo, the plant is macerated in water; fermentation takes place; the liquor becomes of a greenish colour, and in due time is decanted; the colouring principle dissolved by the water absorbs oxygen from the air, and assumes a blue colour, becoming at the same time insoluble; a gradual precipitation takes place, favoured by the addition of lime-water or an alkaline solution; and finally the precipitated matter, having been washed upon linen filters, is dried, shaped usually into cubical masses, and sent into market. Most of the indigo consumed in dyeing is brought from the East Indies, though considerable quantities are imported also from Guatemala, and the northern coast of South America. It was formerly produced in our Southern States, especially Florida, where the plant grows luxuriantly; and it still appears to be prepared there for local use. (See *Am. Journ. of Pharm.*, xxvii. 473.) It is of an intensely blue colour, but assumes a coppery or bronze hue when rubbed by a smooth hard body, as the nail. Heated to 550°, it emits a reddish-violet vapour, which condenses in minute crystals. It is insoluble in water or alcohol, but is readily dissolved by sulphuric acid, which, without destroying its blue colour, so far alters its nature as to render it freely soluble in water, and thus affords a convenient method of applying it to the purposes of dyeing. The solution in sulphuric acid is kept in the shops under the name of *sulphate of indigo*. According to Berzelius, indigo contains, among other ingredients, four distinct principles:—1. a substance resembling gluten; 2. a brown colouring substance; 3. a red colouring substance; and 4. a blue colouring substance, which is the principle upon which its value as a material for dyeing depends, and which seldom constitutes so much as one-half of the indigo of commerce. This blue colouring matter is called *indigotin*. By deoxidizing agents it is deprived of its blue colour, which it recovers by exposure to the air, in consequence of the absorption of oxygen. Such is the case with the acid sulphites, and in a less degree with sulphurous acid. Certain volatile oils are said to have the same effect when boiled with tincture of indigo, as the oil of turpentine, peppermint lavender, juniper, savine, or sage. (*Journ. de Pharm.*, Nov. 1859, p. 399.) Chlorine also destroys the blue colour. M. Preisser has concluded, from an elaborate examination of the *colouring principles* of plants, 1. that these principles are colourless in the young plants; 2. that they acquire colour by combination with oxygen; 3. that all the colouring matters, extracted from any one plant, are produced by the oxidation in different degrees of a single principle; 4. that they are deprived of colour by substances having a strong affinity for oxygen, and reacquire it by contact with oxidizing bodies; and 5. that these colouring principles are acids, and the lakes which they form genuine salts. (*Journ. de Pharm.*, 3e sér., v. 263.) For modes of testing the value of any specimen of indigo, see the *Chemical Gazette* (vii. 463, viii. 443, and x. 159); the *Chem. News* (Dec. 12, 1862, p. 284); and the *Am. Journ. of Pharm.* (xxv. 223). Those methods which are based on the effect of oxidizing agents, by which the colouring matter is destroyed, as chlorate or bichromate of potassa, are asserted by Erdmann to be defective, as it is not only the proper indigo blue that is destroyed, but other principles which are always present in the best

indigo of commerce, especially the indigo brown, and a substance like gelatin usually found in the drug. (*Journ. de Pharm.*, 4e sér., ii. 261.)

Indigo has been proposed by E. Mulder as a test for glucose and fruit sugar, which have the property of changing the blue colour of indigo to white in the presence of the alkalies. To the solution to be examined he adds sulphate of indigo, previously treated with an excess of carbonate of potassa or soda. The addition of the carbonated alkali to the sulphate of indigo scarcely affects the blue colour even at a boiling heat; but if the solution contain glucose or fruit sugar, the blue colour disappears even in the cold, but more rapidly with heat. Common sugar has no such effect. (*Journ. de Pharm.*, Sept. 1860, p. 179; from *Archiv. der Pharm.*, clv. 268.)

Indigo has been introduced to the notice of the profession as a remedial agent. It was at first employed chiefly by the German physicians, from whose statements our knowledge of its physiological action and therapeutical application was derived. Though without odour and taste, it is said, in most individuals, to produce nausea and vomiting, frequently to operate upon the bowels, giving a bluish-black colour to the stools, to render the urine of a dark-violet or dark-green colour, without increasing its quantity, and sometimes to stimulate the secretory function of the uterus. From these statements it would appear to act as an irritant to the alimentary mucous membrane. The character of its general influence upon the system has not been well ascertained. In some instances, it is asserted to have been given in very large doses without any obvious effect. In connection with its influence, the curious fact may be stated, that a colouring matter has been occasionally found in the urine, either spontaneously deposited or separated by the addition of strong muriatic acid, which in colour and other properties, especially that of being sublimable, bears a close resemblance to indigo, if it be not identical with it. (*Chem. Gaz.*, July 15, 1854, p. 267.) The complaints in which indigo has been employed, with supposed advantage, are epilepsy, infantile convulsions, chorea, hysteria, and amenorrhœa. It is given, usually in connection with some aromatic powder, in the dose of a scruple three times a day, which may be increased to a drachm or more; and from half an ounce to an ounce has been employed daily for months together without disadvantage. (See *Am. Journ. of Med. Sci.*, xx. 487.) The general failure of indigo to produce the desired effects in epilepsy, in which it had at one time considerable credit as a remedy, has been ascribed to the use of too small doses. M. Ideler, of Berlin, began with about two drachms daily, and increased gradually to two ounces; but there was great difficulty in reconciling the patient to such doses, on account of the intense nausea produced. (*B. and F. Medico-chirurg. Rev.*, Am. ed., Jan. 1856, p. 198.) W.

INSECT POWDER. Under the name of *Persian* or *Caucasian Insect Powder*, a substance has recently attracted attention in Western Europe, which has long been in extensive use among the people of Western Asia and Eastern Europe, for the destruction of vermin. Among the people south of the Caucasus, it is called *guirila*. It consists of the flowers of the *Pyrethrum carneum*, and *P. roseum*, growing upon the Caucasian mountains, at an elevation of about a mile. It is a coarse powder, of a greenish colour, and pungent odour. It does not appear to be poisonous to man, though it is said to cause some confusion of head in those who sleep in close apartments where much of it is used. Upon the insects, however, which are apt to infest the person of man and animals, as well as bedding and sleeping apartments, it acts very destructively, first stupefying and then killing them. It is scattered over the person, upon the beds, about apartments, &c., and is even employed as a dressing for ulcers and wounds to prevent the formation of maggots. It also answers to preserve dried insects and plants in cabinet collections. The demand for the powder having much increased of late, it is said to be adulterated with the leaves and stems of the plant. (Noodt, *Buchner's Neues Repert.*, vii. 562.) A tincture prepared by macerating one part of the powder in four of alcohol is recommended by F. Jager, a German traveller in the East, as a perfect protection against all kinds of vermin, if applied to any part of the body, diluted with ten times its bulk of water. (*Pharm. Journ.*, July, 1868.) Prof. Maisch has informed the editor of the *Am. Journ. of Pharm.* (March, 1869, p. 128), that in two instances in which he had known it to be tried, it produced a vesicular eruption like that caused by Rhus Toxicodendron. We are not, however, told whether the tincture was diluted with water as recommended by Mr. Jager. W.

IODATE OF POTASSA. This salt has been proposed as a substitute for the chlorate of potassa. MM. Demarquay and Custin propose the following mode of preparation. Take of iodine and chlorate of potassa, each, one part, and mix them with five or six parts of water, previously acidulated with a few drops of nitric acid, and heated to ebullition. As soon as chlorine ceases to escape, treat the liquid with a concentrated solution of chloride of barium. Wash with distilled water, and decompose with dilute sulphuric acid the iodate of baryta precipitated; filter to separate the sulphate of baryta; and slowly evaporate the solution. Wash with distilled water the crystals of iodic acid that are formed, dissolve them in boiling distilled water, and saturate with bicarbonate of potassa. On cooling, the iodate is deposited in small crystals. The authors mentioned have employed the iodate of potassa in all those cases of ulcerated and otherwise diseased mucous membrane of the mouth and fauces, in which the chlorate is usually pre-

scribed, and have found it to produce the same curative effects more quickly, more energetically, and in smaller dose. In the healthy state, it acts remarkably on the pharyngeal and buccal mucous membrane, producing, in the quantity of 20 or 30 grains, a peculiar sense of constriction, and appearing considerably to diminish the mucous secretion. The diseases in which they have found it specially beneficial are diphtheria, mercurial affection of the mouth, and gangrenous stomatitis. The dose used by them was from four to eight grains. (*Dorvault's Rev. Pharm.*, 1858, p. 25.) W.

IODIDE OF AMMONIUM. *Ammonii Iodidum. Hydriodate of Ammonia.* This salt is prepared in the following method by Mr. John A. Spencer, of London. Add to a portion of iodine, placed in a flask with a little water, a solution of hydrosulphuret of ammonia, until the mixture loses its red colour, and is turbid from the separation of sulphur only. Shake the flask, which causes the sulphur, for the most part, to agglomerate; and, having poured off the liquid, boil it until all odour of sulphuretted hydrogen and of ammonia is lost. Then filter the liquid, and, constantly stirring, evaporate it, first with a naked flame until it becomes pasty, and then in a water-bath until it forms a dry salt. Dr. Jacobson prepares the salt by dissolving equiv. weights of pure iodide of potassium and pure sulphate of ammonia, severally, in the smallest quantity of boiling distilled water, mixing and stirring the solutions, and, after the liquid has cooled, adding water containing 15 per cent. of alcohol, and setting it aside for 12 hours. Sulphate of potassa is precipitated; and the liquor, containing iodide of ammonium in solution, is filtered and evaporated to a pellicle. The crystals of the iodide which form are drained; and the mother-liquor and sulphate of potassa may be made to yield a further supply by treating them with dilute alcohol and evaporating. (See *Am. Journ. of Pharm.*, May, 1864, p. 240.) Mr. James F. Babcock, in a communication to the *American Pharm. Association*, at its meeting in 1866, stated that on trial of the first of the above processes, and of all others in which sulphuretted hydrogen or an alkaline sulphuret was employed, the resulting iodide of ammonium retained a portion of sulphur, which caused its colour to change with time to yellow and ultimately to brown, and rendered it unfit for the accurate preparations required in photography. Having tried also other formulas, which he found objectionable on the score of time, cost, &c., he at length satisfied himself that the second process above described was the best in use, and with slight modifications would yield an absolutely pure product. The following is the formula, as recommended by Mr. Babcock. Take of Iodide of Potassium 8 parts; Sulphate of Ammonia 2 parts; Water 4 parts; and Alcohol of 95 per cent. 1 part. Dissolve the Salts, with the aid of heat, in the Water, and allow the solution to stand. After cooling, it deposits most of the sulphate of ammonia formed. Mix the residue at 60° with the Alcohol, which will separate all the remaining sulphate except about one per cent. Then concentrate the solution by evaporation, so that it may crystallize. The crystals obtained are perfectly white iodide of ammonium. By adding alcohol to the mother-liquors, the whole of the sulphate of potassa is precipitated; and the liquid, filtered and evaporated to dryness, furnishes an additional portion of the iodide. The evaporation should be conducted in the dark, or by gas-light. The quantities of material employed yield 4 parts of pure iodide of ammonium. (*Am. Journ of Pharm.*, Jan. 1867, p. 21.) Iodide of ammonium is a crystalline powder soluble in water, and of a taste like that of iodide of potassium, but a little more pungent. It is beautifully white at first, but becomes, in a few weeks, yellowish, and at last brown. It may, however, be easily restored by dissolving the coloured salt in water, treating the solution with a little sulphuretted hydrogen water, until it is rendered colourless, filtering, and evaporating to dryness. (See *Am. Journ. of Pharm.*, March, 1853, p. 134.) This salt has been used externally as a substitute for iodide of potassium. By Dr Pennock it is considered as a good remedy in certain cases of lepra and psoriasis, in the form of ointment, applied by friction in the quantity of half an ounce, morning and evening. The proportions employed are from a scruple to a drachm of the salt to an ounce of lard; the weaker preparation being used when the disease is recent, the stronger when it is chronic. As the iodide is decomposed by the air, the ointment should be kept in well-stopped bottles. Iodide of ammonium may be used internally; in which case it acts as a resolvent, and sometimes as a diuretic; its effects resembling those of iodide of potassium. Dr. B. W. Richardson, of London, has prescribed it, in the dose of from one to three grains, with considerable success, in secondary syphilis, chronic rheumatism, incipient phthisis, and in a variety of forms of scrofulous disorder, attended with glandular enlargements. Dr. Richardson found a liniment, made by dissolving half a drachm of the iodide in an ounce of glycerin, very efficacious in enlarged tonsils, applied every night with a large camel's-hair brush. B.

IODIDE OF ANTIMONY. *Antimonii Iodidum. Teriodide of Antimony.* According to Mr. W. Copney, of London, this iodide may be conveniently prepared by gently heating, in a Florence flask, metallic antimony and iodine, in the proportion of one eq. to three. The elements combine with sudden heat and liquefaction, and, upon the withdrawal of the heat, the iodide formed solidifies, and is removed from the flask by breaking it. Iodide of antimony, as thus prepared, forms a somewhat crystalline, foliated mass, which, when pulverized, yields a deep orange-red powder. By the action of water it is

decomposed. It has been tried as an alterative in a dose varying from a quarter of a grain to a grain, given in the form of pill. B.

IODIDE OF BARIUM. *Barii Iodidum.* This compound may be formed by double decomposition, by adding native carbonate of baryta in powder to a boiling solution of iodide of iron. M. Henry, jun., obtained it by decomposing a solution of sulphuret of barium (see *page* 1061) by a concentrated alcoholic solution of iodine. Sulphur is precipitated, which is separated by filtration, and iodide of barium formed in solution, from which it is obtained in the solid state by rapid evaporation to dryness. Iodide of barium crystallizes in small, colourless needles, which deliquesce slightly, and are very soluble in water. The solution promptly undergoes decomposition by exposure to the air, carbonate of baryta being precipitated, and iodine set free, which colours the solution. It has been used with advantage by Jahn, as an alterative, in scrofulous affections and morbid growths. Lugol employed it in scrofulous enlargements. The dose is the eighth of a grain three times a day, gradually increased to three grains. Biett applied it to scrofulous swellings in the form of ointment, made with four grains of the iodide to an ounce of lard. B.

IODIDE OF CALCIUM. This has been brought into notice by M. Malem, in a memoir published in the *Bulletin Thérapeutique* (Avril 30, 1868), as preferable to any other iodic compound in phthisis. He prepares it in the following manner. Treat a solution of iodide of iron with milk of lime. The liquor thus obtained, being filtered and evaporated, yields crystals of iodide of calcium. Pure iodide of calcium is white, and crystallizes in large plates of a pearly lustre. Procured as recommended, it is yellowish, probably in consequence of the presence of iodine in excess. It is deliquescent, and very soluble in water, and its solution is capable of dissolving iodine added to it. Iodide of calcium is much more unstable than iodide of potassium. When taken, it is rapidly decomposed into hydriodic acid and salts of lime, which are almost immediately absorbed. Most patients bear it very well; and M. Malem had administered it without inconvenience for a year or more. It is especially in scrofulo-tuberculous phthisis that he uses it. After the first doses the appetite is often improved, digestion becomes regular, the respiration deeper and more easy, the cough diminishes, and the expectoration is favourably modified. The muscular system is invigorated, the night-sweats diminish, and the patient increases in weight. Its long-continued use has in general only induced a little constipation, which often disappears upon a diminution of the dose, or suspension of the medicine. From excessive doses M. Malem has seen symptoms of active irritation induced, as increase of the cough, a deep colour of the urine, uneasiness in its discharge, and pain with a sense of fulness in the region of the kidneys. But these symptoms are fugitive, and easily guarded against by a proper regulation of the dose. From one to three or four grains may be given after each meal. (*Ann. de Thérap.*, A. D. 1869, p. 194.) W.

IODIDE OF SILVER. *Argenti Iodidum.* This compound is formed by double decomposition, by adding a solution of iodide of potassium to one of nitrate of silver. It is a greenish-yellow powder, nearly insoluble in ammonia. According to the experiments of M. Fizeau, it has the remarkable property of contracting with heat and expanding with cold, differing in this respect from the chlorides and bromides of the same metal, and the iodides of other metals. (*Journ. de Pharm.*, Dec. 1867, p. 435.) It possesses the general medical properties of nitrate of silver, and, according to Dr. Charles Patterson, of Dublin, may be used without any danger of producing the discoloration of skin which sometimes follows the use of that salt. Dr. Patterson found it generally successful in curing the stomach affections of the Irish peasantry, in the treatment of which nitrate of silver had previously proved useful. He succeeded with it in curing several cases of hooping-cough in a short time, and in greatly relieving a case of dysmenorrhœa of three years' standing. Its effects in epilepsy were least satisfactory. The dose is one or two grains, three times a day, given in the form of pill; for children, from the eighth to the fourth of a grain, according to the age. B.

IODIDE OF SODIUM. *Sodii Iodidum.* This iodide may be prepared either by saturating a solution of caustic soda with iodine, or by double decomposition between iodide of iron and carbonate of soda, precisely as iodide of potassium is obtained by the corresponding processes for that salt. (See *page* 1353.) As only small quantities are likely to be wanted as a medicine, the latter process is preferable; being more easily conducted on a small scale. It is a very soluble white salt, crystallizing in anhydrous cubes from a hot solution, and in oblique rhombic prisms, with four eqs. of water, by spontaneous evaporation. Iodide of sodium has the same therapeutic effects, and is used in the same diseases as iodide of potassium. It is said to be better borne than the latter iodide. In Italy it has been used with remarkable success in constitutional syphilis. The dose is twenty grains, gradually increased to forty, three times a day, dissolved in three fluid-ounces of water. (See Prof. Procter's paper on the preparation of this iodide, in the *Am. Journ. of Pharm.*, July, 1854, p. 305.) At the suggestion of Prof. Gross, it has been very frequently employed by Dr. John J. Black, at the Philadelphia Hospital, as a substitute for iodide of potassium in the treatment of syphilitic affections; and seems to be

not less efficacious than that medicine, while producing none of its unpleasant effects. (*Am. Journ. of Med. Sci.*, July, 1865, p. 87.) B.

IODIDE OF STARCH. Dr. Andrew Buchanan, of Glasgow, proposed this compound as a means of administering iodine in large doses without causing irritation of the stomach. He prepares it by triturating twenty-four grains of iodine with a little water, adding gradually an ounce of very finely powdered starch, and continuing the trituration until the compound assumes a uniform blue colour. The iodide is then dried by a gentle heat, and kept in a well-stopped bottle. The dose is a heaped teaspoonful, given in water gruel, three times a day, and afterwards increased to a tablespoonful. No nicety is necessary in apportioning the dose. In some cases Dr. Buchanan has given half-ounce doses of the iodide three times a day, immediately increased to an ounce. Thus administered iodine produces, according to this writer, little or no irritation of the alimentary canal, but is freely absorbed, as is proved by its detection in large quantities in the secretions. Dr. Buchanan thinks that, by means of the starch, the iodine is converted into hydriodic acid, and in this state enters the circulation. Prof. John C. Dalton, of New York, found that nearly all the animal fluids decompose iodide of starch, and destroy its blue colour. (*Am. Journ. of Med. Sci.*, April, 1856, p. 327.) This result is owing, no doubt, to the alkaline nature of most of the animal fluids, especially those of the duodenum. The iodine, being saturated with the alkali of the fluids, is no longer in the free state, the condition necessary to enable the starch to form the blue compound with it. In other words, the starch compound is decomposed, and the starch set free. He prefers the iodide of starch to any other preparation of iodine for obtaining the alterative apart from the irritant effects of this substance. (*Ibid.*, xx. 213 and 217.) See *Diluted Hydriodic Acid*, page 959.

It is a point of importance, to have the iodide of starch soluble in water. M. Magnes-Lahens, of Toulouse, gained this advantage by his original process of roasting the starch moderately, whereby it is converted into dextrin, before it is mixed with the iodine. Subsequently he abandoned the use of torrefied starch, and now contents himself with making an intimate mixture of iodine and starch, slightly moistened, which he subjects to the heat of a water-bath, until it is converted into the iodide of starch, forming a solution with water of a magnificent blue colour. The heat, thus regulated, disaggregates the starch, without completely transforming it into dextrin, and gives a preparation, in the form of a black powder, resembling the soluble iodide of starch, prepared by M. Quesneville by a secret process. M. Seput, of Constantinople, has also given a formula for this soluble iodide, and for a *syrup* to be made from it. (See *Journ. de Pharm.*, Mars, 1852, p. 202.) M. Soubeiran reported upon these preparations to the Paris Society of Pharmacy, and deemed them ineligible on account of their variable strength in iodine, arising from the greater or less loss of this element during the necessary exposure to heat. Nevertheless, as the syrup is called for, he recommended the following process for making it, availing himself of the observations of his predecessors, which he had occasion to cite in his report. The quantities of the ingredients are here stated in French grammes, each of which weighs about fifteen grains. Triturate thoroughly, in a porcelain mortar, 36 grammes of nitric starch with 4½ grammes of iodine, dissolved in three times its weight of ether, and added in successive portions, until, after the evaporation of the greater part of the ether, a blue powder remains. Introduce this into a weighed, stoppered flask, and, having added 520 grammes of water, expose the whole to the heat of a water-bath, with the stopper at first removed, in order to complete the dissipation of the ether. Afterwards the stopper is replaced, being loosely tied with a packthread, so as to permit of its being raised without being driven out; and the heat is continued for about an hour and a half, when the iodide of starch will be completely formed. The flask is then weighed, and a quantity of water added to it, equal to that lost by evaporation. Lastly, 1040 grammes of sugar are added to the liquid, and dissolved by a gentle heat. By this formula a syrup is prepared, containing a quarter of one per cent. of iodine, a small part of which is in the state of hydriodic acid. The *nitric starch* is used by M. Soubeiran, because it unites with the iodine in much less time than the ordinary starch. It is made by mixing ordinary starch, in the cold, with 150 parts of water, to which 1 part of nitric acid has been added, and allowing the whole to dry in the open air. Three grains of this syrup, diluted with a pint of water, communicate to the liquid a sensible blue tint. This test may serve to determine whether the preparation is of full strength (*Journ. de Pharm.*, Mai, 1852, p. 329.) The dose of the syrup is from one to four tablespoonfuls a day. B.

M. Quesneville, for whom it is claimed that he first introduced iodide of starch into therapeutics, recommends the following method of preparing it. Take of the finest starch, unmixed with that from the potato, 1050 grammes; iodine, in very fine powder passed twice through a sieve of silk, 100 grammes. Carefully mix the powders, and, when the mixture is complete, sprinkle into it gradually, agitating constantly, a mixture of 400 grammes of water and 100 of alcohol. The powder becomes gradually more and more deeply coloured, and soon of a beautiful black. It is to be allowed to stand 15 or 20 days, and is then dried, first by a current of air and then in a stove. When well dried, the powder has no smell of iodine, of which it contains exactly one-tenth of its weight. It is quite insoluble in cold water; but to render it soluble, it is sufficient to heat it in an enameled pan over a very gentle fire with constant agitation; the heat must be removed when a pungent odour is

emitted. The powder thus procured is sufficient for pharmaceutical use. If it be desired to obtain it purer and extremely soluble in cold water, and always of a fine violet-blue, it will be necessary to make with heat a concentrated solution, so as to mark 7 or 8 degrees on the areometer for saline solutions, allow it to stand and settle for several days, then decant the liquor, add a quantity of alcohol just sufficient to precipitate the iodide of starch, put the magma which forms upon a linen cloth, press it as strongly as possible, and dry it by a stove-heat upon shallow dishes. (*Journ. de Pharm.*, Juillet, 1868, p. 30.) W.

IODIDE OF ZINC. *Zinci Iodidum.* This iodide may be formed by digesting an excess of zinc, in small pieces, with iodine diffused in water. Combination takes place, and, by evaporation, a deliquescent, very soluble saline mass is obtained, having a metallic styptic taste, resembling that of sulphate of zinc. It may also be obtained by heating in a matrass a mixture of 20 parts of zinc and 170 of iodine, and subliming into a vial. Thus prepared, it is in the form of white needles. This salt is very liable to spontaneous decomposition.

Iodide of zinc is tonic, astringent, and antispasmodic. In 1853, Dr. Barlow tried it in Guy's Hospital, in cases of chorea, scrofula, cachexia, and some forms of hysteria, with favourable results. (*Med. Times and Gaz*, Nov. 1853, p. 501.) Since then a further experience has confirmed him in his first estimate of its value. He considers it particularly applicable to the treatment of chorea, when complicated with scrofula. (*Ibid.*, August, 1857, p. 195.) The best form of administration is *syrup*, to protect it from change, originally proposed by the late Dr. A. T. Thomson, and made on the same plan as the syrup of iodide of iron. (See *page* 1396.) Mr. A. B. Taylor, of Philadelphia, proposes to form it by gently heating, in an evaporating dish, *twelve drachms and two scruples* of iodine, and *an ounce* of finely granulated zinc, with *nine fluidounces* of water, until they unite, filtering the solution, while hot, on *a pound* (avoird.) of sugar, contained in a wide-mouthed bottle holding a little more than a pint, and adding, through the filter, sufficient water to make the whole measure a pint. This syrup is perfectly clear and colourless, is styptic to the taste, and contains a drachm of iodide of zinc in each fluidounce. (*Am. Journ. of Pharm.*, Jan. 1852, p. 33.) The dose of this syrup is from 20 to 50 drops, sufficiently diluted with water, three times a day.

Iodide of zinc has been used for many years as an external application. Dr. J. J. Ross, of Scotland, employed a solution, containing from 10 to 30 grains to the fluidounce of water, with great advantage in enlarged tonsils, applied by means of a piece of sponge tied to a quill. After the use of the solution for some time, he applied the iodide, rendered liquid by deliquescence, by means of a camel's-hair brush. A solution containing one or two grains to the fluidounce of water has been used as an astringent injection in gonorrhœa. An ointment, made with a drachm of the iodide to an ounce of lard, has been substituted by Dr. Ure for the ointment of iodide of potassium in the treatment of tumours, applied in the quantity of a drachm twice a day. B.

IODO-CHLORIDES OF MERCURY. *Iodides of Calomel. Sel de Boutigny.* These compounds, called subiodide and protiodide of calomel, were brought forward as remedies by M. Boutigny in 1847. To prepare the former, one eq. of iodine and two eqs. of calomel are taken; the calomel is introduced into a matrass, and gradually heated, with agitation, till it begins to sublime; then the iodine is added in small quantities at a time. The combination takes place with some sound, but without sensible loss of iodine. The second compound is prepared in the same mode precisely, one eq. of calomel only being used. (*Arch. Gén.*, Janv. 1857, p. 91.) M. J. Perrens proposes to make them, without the assistance of heat, by rubbing up, in a mortar, the constituents, taken in the proper equivalent quantities. Though called iodides of calomel, the protiodide is a mixture or combination of biniodide and bichloride of mercury, and the subiodide the same, with an excess of calomel. Both these substances are active preparations, and have been employed with success in syphilitic, scrofulous, and cancerous affections. The *subiodide* may be given in pill, in the dose of the twenty-fifth of a grain. The ointment is formed of one part of the subiodide to eighty of lard. It has been used by M. Rochard with advantage in acne rosacea, applied by daily frictions, and as a local application in engorgements of the neck of the uterus. The *protiodide* is used externally only, and should be applied with caution. It acts as a caustic, and may be cast into sticks, like nitrate of silver. An ointment may be made of it, by rubbing one part with twenty of fresh lard. A portion of the ointment, the size of a large *pea*, may be rubbed daily on a scrofulous tumour, in the armpits, or on the inner part of the thigh. Glycerin has been found to be a good excipient. M. Devergie recommends in acne rosacea (couperose) a mixture of 7·5 parts of the salt with 4 of iodide of potassium, 4 of distilled water, and 4 of glycerin, prepared by first triturating the two iodides together, adding the water drop by drop, then filtering, and adding the glycerin. It is applied by means of a hair-pencil. (*Journ. de Pharm.*, 4e sér., v. 199.) B.

IODOFORM. *Iodoformum. Teriodide of Formyl.* (C_2HI_3.) This compound, discovered by Sérullas in 1822, was introduced as a remedy, about the year 1837, by Dr. R. M. Glover, of London, and M. Bouchardat, of Paris. It may be obtained, according to the process of MM. Cornélis and Gille, of Liege, by adding to an alcoholic solution of iodide of potassium, heated to 104°, chlorinated lime, in successive portions, stirring after each addition, until the liquid ceases to assume a dark-red colour. On cooling a confused mass of crystals is deposited, consisting of iodoform and iodate of lime. By treating these with boiling alco-

hol of 90 per cent., the iodoform alone is dissolved; and the alcoholic solution, as it cools, deposits the iodoform in crystals. (*Journ. de Pharm.*, Sept. 1852, p. 196.) It is in the form of small, pearly, yellow crystals, having a strong saffron-like odour, and sweet taste, insoluble in water, but readily soluble in alcohol and ether. It is a volatile substance, soft to the touch, and totally devoid of corrosive properties. Given to the inferior animals it destroys them in a smaller dose than iodine does, producing depression, followed by a stage of excitement, with convulsions, contractions, &c. M. Maître, who has studied its physiological effects on man, states that from a dose of 30 or 40 centigrammes (about 5 or 6 grains) no effects are observed except a slight increase of appetite. Two hours after it has been taken, the presence of iodine can be detected in the urine and the saliva, and nearly three days elapse before the whole is eliminated. It passes off also with the lactic secretion. Given to animals in much larger doses, several grammes, for example, it produces narcotic effects; and two stages in its operation have been noticed; the first marked with more or less prostration, with symptoms of intoxication, the animal tottering, inclining to one side with the head falling, with loss of appetite, but without vomiting. The next day, unless a very large dose has been given, complete recovery takes place. A still larger dose induces the second stage, characterized by a remarkably intense excitation, with anxious breathing, strong and short pulse, a true opisthotonos, sometimes very striking, and convulsive movements of the paws, especially the hinder. The animal seeks an obscure spot, the breath is strongly charged with the smell of iodoform, and death takes place. Dissection reveals nothing to explain the phenomena; though a sensible smell of the drug is exhaled from any part that may be cut, and iodine is found in all the viscera and all the secretions. As to the fatal dose, it varies from 2 grammes in a guinea-pig, to 4 grammes in a dog of medium size. Introduced into the rectum in the form of suppository, it causes unconsciousness of the act of defecation. (*Journ. de Pharm.*, Juillet, 1867, p. 64.) Though containing 29 parts in 30 of its weight of iodine, it has not the least local irritant action. In the form of vapour, it possesses anæsthetic properties, but inferior to those of chloroform. On account of its large proportion of iodine, it is supposed to be capable of replacing that element and the iodides as a remedy, with the advantages of being non-irritant, and of having an organic nature, qualities which favour its absorption and assimilation. Besides the virtues it possesses in common with iodine, it is capable of acting as an anodyne, and is useful in neuralgic affections. The principal diseases in which it has been tried are goitre, rickets, scrofula, phthisis, amenorrhœa, syphilis, glandular tumours, and cutaneous eruptions. In chronic enlargements of the prostate gland, M. Morétin recommends the employment of iodoform as a suppository, made of a scruple of iodoform to an ounce of cacao butter. The dose of iodoform is from one to three grains, three times a day, given in the form of pill. In the treatment of cutaneous diseases and tumours, it is applied in the form of ointment, made by mixing from half a drachm to a drachm with an ounce of lard. M. Besnier recommends it as a valuable application to soft chancres and cancerous ulcers, being sprinkled in the state of powder on the surface. (*Ranking's Abstract*, xlvii. p. 132; from *Bullet. de Thérap.*) M. G. Voelker has employed it, at the suggestion of M. Demarquay, with great relief in cancer of the uterus; the medicine being applied in the form of a suppository, made with 7·5 grains of iodoform and 2·5 drachms of butter of cacao, introduced into the vagina. To maintain the relief it was necessary to repeat the application frequently; but no unpleasant symptom followed. (*Journ. de Pharm.*, Fev. 1868, p. 151.) M. Demarquay has used it largely as an anodyne in cancer of the uterus, and in diseases of the bladder and prostate, introducing it, in the form of suppository, into the vagina in the former case, and into the rectum in the latter. (*Bullet. Gén. de Thérap.*, Mai 15, 1867.) B.

IODOHYDRARGYRATE OF POTASSIUM. It has been found by chemists that different iodides will unite together in different proportions, forming compounds which are called by Berzelius double iodides. Bonsdorff, of Finland, and Dr. Hare, of this city, with greater reason, have viewed these combinations as a peculiar kind of salts, in which one of the iodides performs the part of an acid, the other of a base. The substance, the name of which is placed at the head of this article, is one of these compounds, and was presented to the notice of the profession, as a new remedy of remarkable powers, in February, 1834, by Dr. William Channing, of New York (*Am. Journ. of Med. Sci.*, xiii. 388.) It consists of biniodide of mercury acting as an acid, and iodide of potassium as a base. But as these iodides combine in at least two proportions, it is necessary to indicate the particular combination employed by Dr. Channing.

In a difficult case of pectoral disease, in which the ordinary remedies had failed, Dr. Channing determined to make trial of one of the iodides of mercury. He selected the biniodide; and, in order to have it in the liquid form, as it is insoluble in water, he dissolved it in a solution of the iodide of potassium. He was struck with the chemical changes which the compound solution underwent; and, on pursuing his observations, found that the two iodides really united by the intervention of the water; for, with the aid of an operative chemist, he was enabled by evaporation to obtain them in union, in the form of straw-coloured, needleform, deliquescent crystals. He next found, upon consulting the European authorities, that Bonsdorff, who had taken the lead in investigating similar compounds, had discovered the salt in 1826.

Dr. Channing analyzed the salt with which he experimented, and found that it consisted of one eq. of biniodide of mercury, and two of iodide of potassium. This he determined by ascertaining that an aqueous solution of a little more than eight grains of iodide of potassium would dissolve, and combine with, eleven grains of biniodide of mercury, without being liable to decomposition when largely diluted with water. The combination here indicated corresponds with one of the double iodides of mercury and potassium, described by Thenard. (*Traité de Chimie*, 6ème ed., iii. 493.) The other is represented by this author as consisting of a single eq. of each iodide. When copiously diluted with water, every two eqs. of this iodide let fall one eq. of the mercurial iodide; thus converting the salt into the medicinal double iodide. The same decomposition by means of water is noticed by Dr. Channing. For remarks on these double iodides, see a paper by Mr. Ambrose Smith in the *Am. Journ. of Pharm.* (xii. 265).

Dr. Channing attributes to this preparation the effects of diffusing excitement, and equalizing the circulation. In the different cases in which he tried it, he thought he saw evidence of its favourable influence on the lungs, in allaying cough and improving expectoration; on the alimentary canal, in restoring the healthy secretions; on the kidneys, in reviving their activity; on the skin and cellular tissue, in cicatrizing superficial ulcerations; and on the absorbent and exhalant systems, in causing the disappearance of effused fluid. The principal diseases in which he found it useful were chronic bronchitis, hooping-cough, tonsillitis, chronic gastro-enteritis, dyspepsia, ascites, anasarca, amenorrhœa, leucorrhœa, eruptions, and scrofula. In some cases of phthisis, it mitigated the symptoms, and appeared to prolong life. Dr. Hildreth, of Ohio, has tried the preparation, and reports favourably of its effects in functional dyspepsia, enlargement of the spleen, amenorrhœa, dysmenorrhœa, leucorrhœa, scrofulous affections, ascites, and general dropsy. (*Am. Journ. of Med. Sci.*, xxvi. 312.)

The average dose of the remedy may be stated at the twelfth of a grain three times a day; but in peculiar constitutions, not more than the forty-eighth, the ninety-sixth, or the two hundredth of a grain daily can be borne. For the convenience of physicians who may wish to make trial of the remedy, we give the following formula, deduced from the statements in Dr. Channing's paper. Take of iodide of potassium three and a half grains; biniodide of mercury (red iodide) four and a half grains; distilled water a fluidounce. Dissolve first the iodide of potassium and then the biniodide of mercury in the water. The compound salt in this solution may be assumed to amount to eight grains, though there is a small excess of the iodide of potassium. Of this solution from two to five drops, containing from the thirtieth to the twelfth of a grain, may be given three times a day. It may be administered in the compound syrup of sarsaparilla, which does not decompose it. B.

The iodohydrargyrate of potassium was suggested by F. L. Winckler as a qualitative test of the organic alkaloids, with which it produces insoluble precipitates; and subsequently it has been used by Prof. F. F. Mayer, of New York, for determining the quantity of these alkaloids in any mixture containing them. Prof. Mayer employs, for volumetric analysis, a solution made with 13·546 grammes of corrosive sublimate, 49·8 grammes of iodide of potassium, and a litre of distilled water. For the value, in our own weights and measures, of the gramme and litre, the reader is referred to Tables in the Appendix of this work. Of the solution thus made one cubic centimetre precipitates, of

Aconitia...	0·0267 grammes.	Brucia	0·0233 grammes.	Nicotia ...	0·00405 grammes.
Atropia....	0·0145 "	Veratria...	0·0269 "	Quinia.....	0·0108 "
Narcotina.	0·0213 "	Morphia...	0·0200 "	Cinchonia	0·0102 "
Strychnia..	0·0167 "	Conia	0·00416 "	Quinidia...	0·0120 "

The resulting precipitates are hydriodates of the alkaloids, respectively, with iodide of mercury. They form in acid, neutral, and feebly alkaline liquids, except with the presence of alcohol and acetic acid, by which they are dissolved. For those who may not possess the requisite instruments, Prof. Mayer gives the following table, having reference to ordinary officinal weights. The solution is now made with 16·25 grains of corrosive sublimate, 100 grains of iodide potassium, and enough distilled water to make altogether 12·5 troyounces, or 6000 grains. Of this solution 10 grains will precipitate, of

Aconitia.....	0·0534 grains.	Sulphate of morphia..	0·0500 grains.	Cinchonia.....	0·0204 grains.
Atropia.....	0·0289 "	Conia.....	0·0083 "	Sulphate of cinchonia	0·0250 "
Sulphate of atropia...	0·0389 "	Nicotia	0·0081 "	Quinidia	0·0240 "
Strychnia	0·0334 "	Quinia	0·0216 "	Sulphate of quinidia..	0·0284 "
Brucia.....	0·0466 "	Sulphate of quinia....	0·0296 "	Veratria.....	0·0538 "
Morphia	0·0400 "				

For further observations upon Prof. Mayer's method of effecting the assay of the alkaloids, the reader is referred to the *American Journal of Pharmacy* (Jan. 1863, p. 20). W.

IODO-TANNIN. The solution of iodine in water, made with the assistance of tannic acid, called *iodo-tannin*, has been noticed elsewhere in this work. (See *pages* 483 and 979.) M. Guilliermond, of Lyons, makes a *syrup* of this solution, containing about a grain of iodine to the fluidounce, of which the dose is a tablespoonful, gradually increased. B.

IONIDIUM MARCUCCI. This name has been conferred by Dr. Bancroft upon a

South American plant, supposed to be the source of a medicine used with great asserted advantage in Maracaibo and elsewhere, in some of the horrible cutaneous affections, especially elephantiasis, to which the inhabitants of the tropical regions of this continent are subject. A specimen, however, received from Dr. Bancroft, was found by Sir W. Hooker to be identical with the *Ionidium parviflorum* of Ventinat. The medicine is called by the Indians *cuichunchulli*, and grows in the neighbourhood of Riobamba, a small town at the foot of the great mountain of Chimborazo. It is said to be diaphoretic, diuretic, occasionally sialagogue, and in large doses emetic and cathartic. The root is the part used. It is highly probable that other vegetable emeto-cathartics, having the same property of stimulating the secretions, would be found equally effectual. For an account of what is known in relation to this medicine, the reader is referred to a paper by Dr. Bancroft, republished in the *Am. Journ. of Pharm.* (iii. p. 125). W.

ISATIS TINCTORIA. *Woad. Pastel.* A biennial plant, indigenous in Europe, where it is also cultivated. The leaves have a fugitive pungent odour, and an acrid very durable taste, and have been used in scorbutic affections, jaundice, and other complaints; but the plant is valuable only as the source of a blue dye-stuff, called *woad*, which has been long employed in Europe, though at present nearly superseded by indigo. The leaves are prepared by grinding them to a paste, which is made into balls, placed in heaps, and allowed to ferment. When the fermentation is at an end, the mass falls into a coarse powder, which is the dye-stuff in question. W.

JEFFERSONIA DIPHYLLA. *Twin-leaf.* This is a small, indigenous, herbaceous, perennial plant, belonging to the class and order Octandria Monogynia, and natural order Berberidaceæ. From a knotty rhizoma, furnished with long radicles, arise a naked one-flowered scape about a foot in height, and leaves which stand in pairs on long footstalks. The flower is white, with a four-leaved coloured calyx, and eight petals; and the fruit is a one-celled, obovate, substipitate capsule, dehiscent near the top, with many oblong seeds, united at the base. The plant grows in the Middle and Western States. The rhizoma, which, with the rootlets attached, is the part used, has a brownish-yellow colour, and a bitter, acrid taste, which resides in its cortical part, the inner portion being nearly tasteless. It has been analyzed by Mr. E. S. Wayne, of Cincinnati, and found to contain albumen, gum, tannic acid, starch, pectin, a fatty resin, hard resin, sugar, lignin, and a peculiar acrid principle, having acid properties and resembling polygalic acid, in which it is supposed that the virtues of the root reside. The root is said to be emetic in large doses, tonic and expectorant in smaller doses, and not unlike seneka, as a substitute for which it is sometimes used. (*Am. Journ. of Pharm.*, xxvii. 1.) According to Prof. Mayer, of N. York, the rhizoma of this plant contains a small quantity of berberina, and another alkaloid which is white and in large proportion, as may be inferred from the reactions noticed by Mr. Bentley, of London. The pectin of Mr. Wayne he considers to be saponin. (*Ibid.*, March, 1863, p. 99.) W.

JELLIES. The form of Jelly is sometimes a convenient method of administering medicines, especially the fixed oils, as cod-liver oil and castor oil, which are thus rendered less adhesive to the mouth and fauces, and less liable to leave that disagreeable impression on the palate behind them, which renders such medicines often so offensive that it becomes difficult to administer them. While preparing the jelly, opportunity is also offered for incorporating sugar and aromatics so as very much to cover the offensive taste and odour of the oil. The same remarks are applicable to the resinous juices, as copaiba and some varieties of turpentine, liquid balsam of Tolu, &c. The following is a formula recommended by Messrs. Ed. Parrish and Wm. C. Bakes. "Take of the fixed oil or liquid resin *a troyounce;* honey, syrup, each, *half a troyounce;* gum arabic, in powder, *two drachms;* Russian isinglass, *forty grains;* orange-flower water, *six fluidrachms.* Dissolve the isinglass, with the aid of heat, in half a fluidounce of the orange-flower water, replacing the water as it evaporates. Triturate the other ingredients, with the remainder of the orange-flower water, into a homogeneous mass in a warmed mortar, then add the hot solution of isinglass, stir the mixture as it cools, and set it aside to gelatinize." (*Am. Journ. of Pharm.*, Jan. 1861, p. 4.) Any other aromatic water may be substituted for that of the orange-flower, and cinnamon water diluted with an equal measure of pure water would probably better cover the offensive taste. In reference to cod-liver oil, the bitter-almond or cherry-laurel water would be still more effectual; care, however, being taken in this case, that the water is duly diluted, lest too large a dose of it might be administered. W.

KALMIA LATIFOLIA. *Laurel. Mountain Laurel. Broad-leafed Laurel. Calico-bush.* This well-known evergreen inhabits all sections of the United States, being especially abundant on the sides of hills and mountains, which it adorns in summer with its elegant flowers. It is from three to ten feet in height. The leaves are possessed of poisonous, narcotic properties, and have been used in medicine. They have been analyzed by Mr. Charles Bullock, of Philadelphia, and found to contain gum, tannic acid, resin, chlorophyll, fatty matter, a substance resembling mannite, an acrid principle, wax, extractive, albumen, yellow colouring matter, lignin, and salts of potassa, lime, and iron. (*Am. Journ. of Pharm.*, xx. 264.) They are said to prove fatal to sheep and some other animals, but are eaten with impunity by deer, goats, and partridges. Dr. Barton states, in his "Col-

lections," that the Indians sometimes use a decoction of the leaves to destroy themselves. It is said that death has been occasioned by eating the flesh of partridges and pheasants which have fed upon them during winter. Dr. N. Shoemaker published, in the *North American Medical and Surgical Journal*, two cases of poisoning which resulted from eating a pheasant, in the craw of which laurel leaves were found. The symptoms were nausea, temporary blindness, pain in the head, dyspnœa, pallid countenance, cold extremities, and a very feeble pulse, which in one case was for some time absent at the wrist, in the other beat only forty strokes in the minute. In both cases relief was afforded by vomiting, produced by a tablespoonful of flour of mustard mixed with warm water. A case of similar poisoning is related in the *Edinburgh Medical Journal* (May, 1856, p. 1014), in which epigastric tension and uneasiness, glowing heat of the head, loss of sight, coldness of the extremities, general prostration, and twitchings of the muscles were the prominent symptoms, followed by nausea and full vomiting, which afforded some relief. But feelings of formication and weakness of the limbs, with great prostration of the circulation, remained for several hours, requiring the use of stimulants.

Dr. Barton was informed that the powdered leaves were employed by an empiric with success in certain stages of fever; and Dr. Thomas, in an inaugural dissertation, published at Philadelphia, A. D. 1802, states that an obstinate case of diarrhœa was cured by a decoction, made by boiling an ounce of the leaves in eight ounces of water down to four ounces. Thirty drops were given six times a day; but this quantity produced vertigo, and the dose was afterwards repeated only four times daily. The leaves are said to have been used advantageously in syphilis. Externally applied, in the shape of ointment or decoction, they have been found useful in tinea capitis, psora, and other cutaneous affections; but caution is necessary in their application, as, according to Dr. Barton, nervous symptoms have resulted from the external use of the decoction. Dr. Bigelow has seen the recently powdered leaves given in doses of from ten to twenty grains, without perceptible effect.

It is probable that other species of Kalmia, as *K. angustifolia* or *sheep-laurel*, and *K. glauca* or *swamp-laurel*, have properties identical with those of *K. latifolia*. A decoction of the leaves of K. angustifolia is used by the negroes of North Carolina as a wash for an ulcerative affection between the toes. W.

LABDANUM. *Ladanum.* A resinous substance, obtained from various species of Cistus, especially *C. Creticus*, *C. ladaniferus*, and *C. laurifolius*, small evergreen shrubs, inhabiting the islands of the Grecian Archipelago, and the different countries bordering on the Mediterranean. Upon the leaves and branches of these shrubs a juice exudes, which is collected by means of an instrument resembling a rake, with leather thongs instead of teeth, which is drawn over the plant. The juice adheres to the pieces of leather, and is afterwards separated. It is said that labdanum was formerly collected by combing the beards of goats which had been browsing upon the leaves of the cistus; and Landerer states that it is at the present time gathered in the same way in Cyprus from sheep, whose fleeces become loaded with it while they are pasturing. (See *Pharm. Journ.*, xi. 6.) It comes chiefly from the Grecian Islands. Two varieties exist in commerce. The *purest labdanum* is in masses of various sizes, sometimes weighing several pounds, enclosed in bladders, dark-red almost black externally, grayish internally when first broken, of the consistence of a plaster, softening in the hand and becoming adhesive, of an agreeable balsamic odour like that of amber, and of a bitter, balsamic, somewhat acrid taste. It is very inflammable, burning with a clear flame. On exposure it becomes dry, porous, and brittle. Little of this variety is found in the markets. *Common labdanum* is in contorted or spiral pieces, light, porous, blackish-gray, hard and brittle, not softening between the fingers, similar in odour and taste to the preceding variety, but less inflammable, and mixed with sand and other earthy matters, which are obvious to the sight. A specimen exhibited at the International Exhibition of 1862, at London, was in flattish pieces, an inch or more thick, with remains of leaves on one side, of a very dark greenish-brown colour, and a granular somewhat shining fracture. Guibourt found in 100 parts of the labdanum in masses, 86 parts of resin with a little volatile oil, 7 of wax, 1 of watery extract, and 6 of earthy substances and hair. In the contorted variety, Pelletier found 20 per cent. of resin, 3·6 of gum with malate of lime, 0·6 of malic acid, 1·9 of wax, 1·9 of volatile oil including loss, and 72 of ferruginous sand.

Labdanum is a stimulant expectorant, and was formerly given in catarrhal and dysenteric affections. At present it is employed in plasters, but seldom even for that purpose in the United States. It is sometimes used in fumigation. W.

LAC. A resinous substance obtained from several trees growing in the East Indies, particularly from *Croton lacciferum*, and two species of Ficus, *F. religiosa*, and *F. Indica*. It is found in the form of a crust, surrounding the twigs or extreme branches, and is generally supposed to be an exudation from the bark, owing to the puncture of an insect, belonging to the genus *Coccus*, and denominated *C. Lacca*. By some it is thought to be an exudation from the bodies of the insects themselves, which collect in great numbers upon the twigs, and are embedded in the concreted juice, through which the young insects eat a passage and escape. Several varieties are known in commerce. The most common are *stick-lac*, *seed-lac*, and *shell-lac*.

Stick-lac is the resin as taken from the tree, still encrusting the small twigs around which it originally concreted. It is of a deep reddish-brown colour, of a shining fracture, translucent at the edges, inodorous, and of an astringent, slightly bitterish taste. Its external surface is perforated with numerous minute pores, as if made by a needle; and when broken it exhibits many oblong cells, often containing the dead insect. When chewed it colours the saliva beautifully red, and, when burnt, diffuses a strong, agreeable odour. It is in great measure soluble in alcohol.

Seed-lac consists of minute irregular fragments, broken from the twigs, and partially exhausted by water. It is of a light or dark-brown colour, inclining to red or yellow, feebly shining, almost tasteless, and capable of imparting to water less colour than the stick-lac, sometimes scarcely colouring it at all. It is occasionally mixed with small fragments of the twigs.

Shell-lac is prepared by melting the *stick-lac* or *seed-lac*, previously deprived of its soluble colouring matter, straining it, and pouring it upon a flat smooth surface to harden. It is in thin fragments of various sizes, from half a line to a line thick, often somewhat curved, of a lighter or darker brown colour inclining more or less to red or yellow, shining, more or less transparent, hard and brittle, inodorous and insipid, insoluble in water, but easily and almost entirely soluble in alcohol, especially with the aid of heat. According to Oberdörffer, cold ether takes from shell-lac only about 5 per cent., consisting of wax; and adulteration with resins soluble in ether is thus readily detected. (See *Am. Journ. of Pharm.*, July, 1861, p. 313.)

A variety of lac is mentioned by writers in the form of cakes, called *cake-lac* or *lump-lac* (*lacca in placentis*); but this is at present rare in commerce.

According to John, lac consists of resin, colouring matter, a peculiar principle insoluble in alcohol, ether, or water, called *laccin*, a little wax, and various saline matters in small proportion. The resin, according to Unverdorben, consists of several distinct resinous principles differing in their solubility in alcohol and ether. The laccin is nearly or quite wanting in *shell-lac*, which also contains scarcely any of the colouring principle. Mr. Hatchett found in *stick-lac* 68 per cent. of resin, and 10 of colouring matter; in *seed-lac* 88·5 per cent. of resin, and 2·5 of colouring water; in *shell-lac* 90·9 per cent. of resin, and 0·5 of colouring matter. The other constituents, according to this chemist, are wax and gluten, besides foreign matters. M. Schapringer gives a method of detecting lac in any mixture, through the property of its colouring matter, which he calls *coccine*, of being deep-red in acid solutions, and becoming violet upon the neutralization of the acid by an alkali. To the suspected substance an excess of acetic or muriatic acid is added; the turbid liquid is heated till it becomes limpid, and the resin has agglomerated; after which the liquid is decanted, and ammonia is added in excess. The red colour, more or less violet, will soon become manifest if lac is present. A quarter of a grain of the lightest-coloured lac found in commerce may be thus revealed (*Journ. de Pharm.*, 4e sér., v. 239.)

Lac in its crude state is slightly astringent, and was formerly used in medicine; but at present it is not employed. Shell-lac is wholly inert. Stick-lac and seed-lac are used on account of the colouring principle which they contain. Shell-lac, as well as the other varieties deprived of their colouring matter, is applied to numerous purposes in the arts. It is the chief constituent of *sealing wax*. The best *red sealing wax* is made by melting together, with a very gentle heat, 48 parts of shell-lac, 19 of Venice turpentine, and 1 of balsam of Peru, and mixing with the melted mass 32 parts of finely powdered cinnabar. But common resin is often substituted in part for the lac, and a mixture of red lead and chalk for the cinnabar. The best *black sealing wax* consists of 60 parts of lac, 10 of turpentine, and 30 of levigated bone-black; the best *yellow sealing wax*, of 60 parts of lac, 12 of turpentine, and 24 of chromate of lead. (*Berzelius.*) Lac is also used as a varnish, and forms an excellent cement for broken porcelain and earthenware. For a method of preparing a colourless varnish from lac the reader is referred to the *Pharmaceutical Journal* (Dec. 1864, p. 338). Lac has been highly recommended as an adhesive material for the dressing of wounds, ulcers, &c. It is prepared for use by dissolving, with the aid of a gentle heat, in alcohol contained in a glass bottle, sufficient lac to give it a gelatinous consistence, and then closing the bottle. It is used by simply spreading it on the bandages. W.

LACTATE OF ZINC. *Zinci Lactas.* This salt may be prepared by first obtaining lactate of potassa by double decomposition between lactate of lime and carbonate of potassa, and then adding the solution of the alkaline lactate, filtered from the carbonate of lime, to one of acetate of zinc. By a new double decomposition, lactate of zinc, on account of its sparing solubility in cold water, is deposited in crystals, and acetate of potassa remains in solution. The crystals may be purified by dissolving them in boiling water, and recrystallizing. This salt is in the form of white plates, soluble in sixty parts of cold water, and six at the boiling temperature. It is insoluble in alcohol. Its taste is highly saccharine, with a styptic after-taste. Exposed to heat it bears a temperature of 392° without decomposition.

Lactate of zinc was brought forward by M. Herpin as a remedy in epilepsy; and, after a trial of it in this disease for nearly two years, he concluded that it is at least as

efficacious as the oxide, with the advantages of being better borne, and more easily taken. The dose is two grains three times a day, given in pill, and gradually increased until it amounts to ten grains. The best time for taking it is about an hour after meals. In M. Herpin's cases it was continued for from five to twelve months. B.

LAKES. These are compounds of vegetable or animal colouring principles with alumina or other metallic oxide, and are usually obtained by adding alum or bichloride of tin to the solution of the colouring matter in water, and precipitating by means of an alkali. The alumina or oxide of tin unites with the colouring matter at the moment of separation, and forms an insoluble compound. Lakes are obtained in this way from cochineal, madder, Brazil wood, seed-lac, French berries, &c. They are used in painting. W.

LAURUS NOBILIS. *The Bay Tree.* The fruit of this tree, commonly called *bay berries*, was one of the officinals of the late London Pharmacopœia, but has been omitted in the British. The tree belongs to Enneandria Monogynia in the Linnæan system, and to the natural order of Lauraceæ. The following is the generic character of Laurus as given by Lindley in his Flora Medica. "*Flowers* diœcious or hermaphrodite, involucrated. *Calyx* four-parted; segments equal, deciduous. *Fertile stamens* twelve in three rows; the outer alternate with the segments of the calyx; all with two glands in the middle or above it. *Anthers* oblong, two-celled, all looking inwards. *Fertile flowers* with two to four castrated males surrounding the ovary. *Stigma* capitate. *Fruit* succulent, seated in the irregular base of the calyx. *Umbels* axillary, stalked." Laurus nobilis is an evergreen tree, attaining in its native climate the height of twenty or thirty feet. Its leaves are alternate, on short petioles, oval-lanceolate, entire, sometimes wavy, veined, of a firm texture, smooth, shining, deep-green upon their upper surface, paler beneath. The flowers are diœcious, of a yellowish-white colour, and placed, in small clusters of three or four together, upon a common peduncle in the axils of the leaves. The corolla is divided into four oval segments. The fruit is an oval berry, of the size of a small cherry, and when ripe of a dark-purple, nearly black colour. The bay tree, so famous among the ancients, is a native of the countries bordering on the Mediterranean. Its leaves and fruit, and an oil expressed from the latter, are the parts used.

The *leaves* have a fragrant odour, especially when bruised, and a bitter, aromatic, somewhat astringent taste. They yield by distillation a greenish-yellow volatile oil, upon which their properties chiefly depend. Water distilled from them has their peculiar odour. The *berries* when dried are black and wrinkled, and contain two oval fatty seeds, within a thin, friable envelope; or they may be considered as drupes, with a kernel divisible into two lobes. They have the same aromatic odour and taste as the leaves, but are more pungent. Besides an essential oil, they contain also a fixed oil, which may be separated by expression or decoction. The *expressed oil*, which is obtained from the fresh fruit, is concrete, of a greenish colour, and retains a portion of the volatile oil, which renders it agreeably aromatic. Lard, impregnated with the odorous principle of the berries, and coloured green, is said to be often substituted for the genuine expressed oil. The sophistication may be detected by means of boiling alcohol, which dissolves the laurel oil. The leaves, berries, and oil of the bay tree are excitant and narcotic; but at present are never used internally as medicines, and in this country are scarcely employed in any manner. Their chief use is to communicate a pleasant odour to external remedies. Dr. A. T. Thomson says that he has found an infusion of the berries useful in impetigo. W.

LAWSONIA INERMIS. *Henna Plant.* This belongs to Octandria Monogynia in the Linnæan system, and to the natural family of Salicariæ. It is a shrub growing in the Levant, Egypt, Persia, and India, and well known as the source of a dye-stuff denominated *henna*, much used throughout the Mahomedan countries of the East. It is largely cultivated in Egypt. The flowers have a strong pungent odour; and a distilled water is prepared from them, used by the women as a cosmetic. The fruit is thought to have emmenagogue properties. But the leaves are the part which constitute the henna of commerce. They are used by the females to give an orange colour to their feet and hands, and a golden hue to their hair. They are also employed to stain common wood in imitation of mahogany. Henna is in the form of powder, which is strongly astringent. It has been chemically examined by Abd-el-Aziz, of Cairo, Egypt, a former pupil in the laboratory for dyeing, connected with the famous manufacture of the Gobelins at Paris. He found in it a brown substance, of a resinoid fracture, having the chemical properties which characterize the tannins, and therefore named by him *hennotannic acid*. (*Journ. de Pharm.*, Janv. 1863, p. 35.) Henna is used in medicine, both internally and locally, as a remedy in leprosy and other affections of the skin. The fresh juice of the plant is said by Ainslie to be applied to the same purpose. (*Mérat et De Lens.*) W.

LEDUM PALUSTRE. *Marsh Tea. Rosmarinus Sylvestris.* A small evergreen shrub, growing in swamps and other wet places in the northern parts of Europe, Asia, and America, and in the mountainous regions of more southern latitudes. The leaves have a balsamic odour, and an aromatic, camphorous, bitter taste; and contain, among other ingredients, volatile oil and tannin. They are thought to possess narcotic properties, and

have been employed in exanthematous diseases to allay irritation, in hooping-cough, in dysentery, and in various cutaneous affections, particularly leprosy and scabies. In complaints of the skin, they are used both internally and externally in the form of decoction. When placed among clothes, they are said to prevent the attacks of moths. In Germany they are sometimes substituted for hops in the preparation of beer. *Ledum latifolium*, or *Labrador tea*, which is a larger plant than the preceding, is a native of North America, growing in damp places in Canada and the northern parts of the United States. The leaves have an agreeable odour and taste, and are esteemed pectoral and tonic. They are said to have been used as a substitute for tea during the war of independence. W.

LEEK. *Porrum. The Bulb of Allium Porrum.* The leek is a biennial bulbous plant, growing wild in Switzerland, and cultivated in the gardens of Europe and this country for culinary purposes. All parts of it have an offensive pungent odour, and an acrid taste, dependent on an essential oil, which is in a great measure dissipated by decoction, and may be obtained separate by distillation. The bulb, which is the medicinal portion, consists of concentric layers, like the onion, which it resembles in medical properties, though somewhat milder. It is generally stimulant, with a peculiar direction to the kidneys. The expressed juice may be given in the dose of a fluidrachm, mixed with syrup. This species of Allium is not used medicinally in the United States. W.

LEONURUS CARDIACA. *Common Motherwort.* (*Gray's Manual*, p. 317.) A perennial labiate herb, thought to be of foreign origin, but growing wild in this country in waste places, around dwellings, &c. The whole plant is used. It has a peculiar aromatic odour and a bitterish somewhat pungent taste, which it no doubt owes to a volatile oil. Its vernacular name implies its possession, in common estimation, of some influence over the uterine functions; and, in the form of infusion or decoction, it is sometimes used in amenorrhœa, suppression of the lochia, and in hysterical affections. W.

LIATRIS SPICATA *Gay-feather. Button Snakeroot.* An indigenous perennial plant, growing in natural meadows and moist grounds throughout the Middle and Southern States. It has a tuberous root, and an erect annual stem, which terminates in a spike of beautiful, purple, compound flowers, appearing in August. The root is said by Schœpf to have a terebinthinate odour; and a warm, bitterish, terebinthinate taste; to be possessed of diuretic properties; and to be useful in gonorrhœa and sorethroat; being employed internally in the shape of decoction in the former complaint, and as a gargle in the latter. Pursh informs us that *L. scariosa* and *L. squarrosa* are known in Virginia, Kentucky, and the Carolinas, by the name of *rattlesnake's master;* and that their roots are employed to cure the bite of the rattlesnake, being bruised and applied directly to the wound, while their decoction in milk is taken internally. According to Dr. William P. C. Barton, all the tuberous rooted species of Liatris are active plants, and appear to be diuretic. W.

LIGUSTICUM LEVISTICUM. *Lovage.* An umbelliferous plant, growing wild in the South of Europe, and cultivated in gardens. The whole plant has a strong, sweetish, aromatic odour, and a warm, pungent taste. When wounded it emits a yellow, opaque juice, which concretes into a brownish resinous substance, not unlike opopanax. The roots, stems, leaves, and seeds have all been employed; but the last have the aromatic properties of the plant in the highest degree. They are small, ovate-oblong, somewhat flattened, curved, strongly ribbed, and of a yellowish-brown colour. The medical properties of lovage are closely analogous to those of angelica. It is a stimulant aromatic, and has been employed as a carminative, diaphoretic, and emmenagogue. The best form for administration is that of infusion. The colouring principle has been isolated by M. J. Nicklès, who gives it the name of *ligulin*, and suggests an important application of it that may be made in testing drinking water. If a drop of its alcoholic or aqueous solution is made to fall into distilled water, it imparts to the liquid its own fine crimson red colour, which undergoes no change; but if limestone water be substituted, the red colour disappears in a few seconds, and is followed by a beautiful blue. (*Journ. de Pharm.*, Mai, 1859, p. 329.) W.

LIGUSTRUM VULGARE. *Privet.* A shrub from four to ten feet in height, growing wild both in Europe and the United States, usually in hedges and by the roadside. The *leaves*, which have an astringent, bitter taste, and the *flowers*, which are small, snow-white, and of an agreeable odour, have been used in the form of decoction, in sorethroat, and aphthous and scorbutic ulceration of the mouth. The *berries* are black, have a sweetish bitter taste, and are said to possess purgative properties, and to colour the urine brown. They are sometimes used for dyeing. The case of a child, between two and three years old, is recorded by Mr. James Cheese in the *Lond. Pharm. Journ.* (2d ser., viii. 607), in which the eating of privet berries appeared to be the remote cause of death, having induced active purgation, and probably set on foot an inflammation of the bowels, which ultimately proved fatal. The bark was analyzed by M. G. Potex, who found a peculiar substance, which he denominated *ligustrin*, besides mannite, sugar, muco-saccharine matter, starch, chlorophyll, bitter extractive, bitter resin, tannin, albumen, and salts. (*Am. Journ. of Pharm.*, xii. 347.) W.

LILIUM CANDIDUM. *Common White Lily.* This well-known plant is a native of

Syria and Asia Minor, but has been long cultivated in gardens. The bulb, which consists of imbricated fleshy scales, is without odour, but has a peculiar, disagreeable, somewhat bitter, and mucilaginous taste. It contains much mucilage, and a small proportion of an acrid principle, which is dissipated or destroyed by roasting or boiling. In the recent state, it is said to have been employed with advantage in dropsy. Boiled with water or milk, it forms a good emollient cataplasm, more used in popular than in regular practice. The flowers have an agreeable odour, which they impart to oil or lard; and an ointment or liniment is sometimes prepared from them, and used as a soothing application in external inflammations. A case is recorded by Dr. Jeffries Wyman, of Boston, in which a little girl appeared to have been poisoned by the pollen of the tiger lily (*Lilium bulbiferum?*), which the child had introduced into her nostrils and probably swallowed. She was affected with vomiting, purging, drowsiness, &c., from which, however, she recovered. (*Am. Journ. of Med. Sci*, Jan. 1863, p. 271.) W.

LINT. As an object of great importance to the surgeon, and a necessary article of sale to the apothecary, this seems not only to admit, but to require a brief notice in the present place. The term lint strictly speaking is applicable, as its name implies, to a substance prepared from linen. It is in fact linen made soft and somewhat fleecy by various mechanical processes, so as to render it suitable for the dressing of wounds. The qualities required in good lint are 1. perfect softness to prevent mechanical irritation to the wound, 2. looseness of texture to render it capable of absorbing the secretions from the surfaces to which it is applied, 3. a certain tenacity so that it may receive unctuous dressings, yet with a facility of being torn in one direction, and 4. sufficient firmness of fibre to prevent small portions from being easily separated, and remaining as foreign bodies in the wound. As formerly and still frequently made for domestic purposes, it consists of old linen scraped by means of a knife with the hand, and thus brought into a soft flocculent state, almost destitute of visible fibres. It is obvious that, though this answers some of the above requisitions, it entirely fails to answer others, and is unfit for general surgical use. It will not readily admit of the application of cerates, and must very often leave portions of its substance in the wound, to serve as future sources of irritation. Much better is the old-fashioned lint, made by machines worked by the hand. This was formerly, and may still be made, in large quantities. Old linen was used for the purpose, such as shirts, sheets, tablecloths, &c., and generally in irregular pieces. This was first cleansed thoroughly by washing with soap and water, or by boiling with a weak ley of soda or pearlash. Sometimes, when coloured, it was bleached before being washed. Thus prepared, it was operated on by a simple machine, in which the rag, wrapped round a cylinder, was submitted to the interrupted action of a knife, made to descend upon it at intervals of one-eighth of an inch, so as to cut the thread in one direction. On being removed from the machine, the cut ends of the thread became untwisted and loose, so as to give a flossy character to the fabric. To render it smooth, it was passed through rollers, and its ragged edges were trimmed. Of course it had different degrees of fineness according to the character of the rags used; and this diversity rendered it fit for different purposes; the finer pieces being used merely as a dressing with unctuous matter to exclude the air, while the thicker were better adapted to the absorption of the liquid secretions.

In the progress of improvement, machines were invented and patented for manufacturing lint on the large scale. Thus made, it is distinguished in the shops as *patent lint*. This is generally prepared out of cloth manufactured for the purpose, and therefore has whatever advantage may be derived from uniformity of shape and consistence. In other respects, it is doubtful whether it has any superiority over the old-fashioned article; especially, as, in consequence of competition, cotton, being the cheaper article, has frequently been in part or altogether substituted for linen. It is said that lint may be rapidly prepared, by attaching a piece of linen to the toothed cylinder of the common carding machine. (*Med. and Surg. Reporter*, Oct. 4, 1862.)

Cotton is in several respects inferior to linen for the preparation of lint; and, unless its presence in any manufactured article sold by this name be made known, it should be looked on as a fraudulent substitution. Its fibre is less soft and therefore more likely to irritate; it has much less absorbing power; and it conveys heat less rapidly. The following are methods by which it may be distinguished. (*Dr. Elsner.*) 1. A linen thread when held erect, and set on fire, appears, after the flame is extinguished, in a smooth continuous form, while cotton thread similarly treated has a tufted aspect. 2. Under a microscope which magnifies 300 diameters, the linen fibre appears to be a straight nearly solid cylinder, with a slender central canal; the cotton, flattened as a piece of tape, with a wide canal, and often twisted like a corkscrew. 3. The potassa test, proposed by Böttger, consists in exposing the doubtful substance to the action of a boiling concentrated solution of potassa. If made of linen, it will in two minutes assume a deep-yellow colour; if of cotton, it will either remain colourless, or will become very faintly yellow; and if the texture be composed of both, it will exhibit a streaked or mottled aspect. The examination must be quickly made, as the yellow colour of the potassa becomes faint with time. 4. Sulphuric acid dissolves the linen fibre, while it leaves that of cotton little changed. 5. Linen thoroughly oiled has the transparent appearance of oiled paper; cotton remains white and opaque. 6. Tinctures of all organic red dye-stuffs, as cochineal, madder, &c., give a much deeper colour to linen than to cotton, and cause a mottled appearance when the two are mixed.

Tow, and hemp in the state of *oakum*, have been employed for dressing wounds; but they are only applicable as exterior dressings to absorb the pus, when the discharge of this is very copious. Dr. L. A. Sayre, Surgeon of Bellevue Hospital, N. Y., has found picked oakum preferable to lint as an immediate dressing to suppurating wounds, and ascribes its superiority to certain mechanical advantages as regards absorption. (*Bost. Med. and Surg. Journ.*, lxvii. 84.) Without adopting the theory, we may well admit the fact in certain cases; as few local applications are more efficient than tar properly used in promoting granulation in indolent suppurating surfaces; and oakum consists of hemp saturated with tar. *Charpie*, so much used by French surgeons in dressing wounds from the bottom, generally consists of bundles of straight threads, each four or five inches long, made by unravelling old rather coarse linen. It is much inferior as a dressing for wounds to our best forms of lint. On the subject of lint, we would refer the reader to an article in the *Pharmaceutical Journal* (x. 241); and to another in the *American Journal of Pharmacy* (July, 1861, p. 359). W.

LINUM CATHARTICUM. *Purging Flax.* This has been brought hither from the first part of the work, because, though formerly one of the Edinburgh officinals, it was discarded in the preparation of the present British standard. The character of the genus to which this plant belongs will be found under *Linum*, in *Part* I. Purging flax is an annual plant, six or eight inches high, having erect, slender stems, dichotomous near the summit, furnished with opposite, obovate-lanceolate, entire leaves, and bearing minute white flowers, the petals of which are obovate and acute. It is a native of Europe, and not found in the United States, where it is never employed as a medicine. The whole plant is very bitter, and somewhat acrid, and imparts its virtues to water, which acquires a yellow colour. It appears to owe its activity to a peculiar drastic principle, which has received the name of *linin*, and which is afforded most largely by the plant after the flower has fallen. (*Pharm. Central Blatt*, 1844, p. 110.) Purging flax formerly enjoyed some reputation in Europe as a gentle cathartic, but fell into disuse. Attention has been again called to it as an excellent remedy in muscular rheumatism, catarrhal affections, and dropsy with disease of the liver. From four to eight grains of the extract, given twice or thrice daily, are said to operate as a purgative and diuretic, without inconvenience to the patient. (*Medical Times*, July, 1850.) A drachm of the powder, or an infusion containing the virtues of two or three drachms of the herb, may be taken for a dose. W.

LIQUIDAMBAR STYRACIFLUA. *Sweet Gum.* An indigenous tree, growing in different parts of the U. States from New England to Louisiana, and flourishing also in Mexico, where, as well as in our Southern States, it sometimes attains a great magnitude. In warm latitudes a balsamic juice flows from its trunk when wounded. This has attracted some attention in Europe, where it is known by the name of *liquidamber*, or *copaim balsam*, and is sometimes, though erroneously, called *liquid storax*. It is not afforded by the trees which grow in the Middle Atlantic States, but is obtained in the Western States bordering on the Ohio, and in those further south, as far as Mexico. It is a liquid of the consistence of thin honey, more or less transparent, of a yellowish colour, of a peculiar, agreeable, balsamic odour, and a bitter, warm, and acrid taste. By cold it becomes thicker and less transparent. It concretes also by time, assuming a darker colour. It is sometimes collected in the form of tears, produced by the spontaneous concretion of the exuded juice. According to M. Bonastre, it contains a colourless volatile oil, a semi-concrete substance which rises in distillation and is separated from the water by ether, a minute proportion of benzoic acid, a yellow colouring substance, an oleo-resin, and a peculiar principle, insoluble in water and cold alcohol, for which M. Bonastre proposes the name of *styracin*. The proportion of benzoic acid is greatly increased by time. Mr. Hodgson obtained from a specimen which he examined 4·2 per cent. (*Journ. of the Phil. Col. of Pharm.*, vi. 190.) According to Mr. Daniel Hanbury, the acid contained in it is the cinnamic, as is the case in all the products of the liquidambar trees. (*Am. Journ. of Pharm.*, xxix. 478.) Examined by Mr. W. P. Creecy, of Mississippi, it was found, besides a volatile odorous principle, and 30 per cent. of a hard resin, to contain cinnamic acid as the prominent acid ingredient, yet associated with a small proportion of benzoic acid. (*Ibid.*, May, 1860, p. 199.) Prof. Procter, on a subsequent examination of the product, could not detect benzoic acid, and states that little, if any of that acid exists in it, and that what had been taken for benzoic acid by the earlier examiners was really the cinnamic. (*Am. Journ. of Pharm.*, Jan. 1866, p. 38.)

Another product is said to be obtained from the same tree by boiling the young branches in water, and skimming off the fluid which rises to the surface. It is of a thicker consistence and darker colour than the preceding, is nearly opaque, and abounds in impurities. This also has been confounded with liquid storax, which it resembles in properties, though derived from a different source. It is said to be used in Texas in coughs. (Gammage, *N. O. Med. and Surg. Journ.*, xii. 636.)

Liquidamber may be employed for the same purpose as storax, but is very seldom used, and is almost unknown in the shops of the United States. The concrete juice is said to be chewed in the Western States in order to sweeten the breath. Dr. Gammage states that the juice is employed popularly in Texas as an addition to excitant ointments. According to C. W. Wright, of Louisville, Ky., the bark of the tree is used with great advantage

in the Western States in the diarrhœa and dysentery of summer, especially in children. It is taken in the form of syrup, which may be prepared from the bark in the same manner as the syrup of wild-cherry bark, according to the U. S. Pharmacopœia. The dose is a fluidounce for an adult, repeated after each stool. (*Am. Journ. of Med. Sci.*, N. S., xxxii. 126.) The editor of the *Va. Medical Journal* (Aug. 1856, p. 143) states that the use of a decoction of the bark in milk is common in many parts of Virginia, as a remedy in the diarrhœa of children. Prof. Procter states that the leaves and capsules of the tree have a somewhat aromatic odour when bruised, and are decidedly acid to the taste and to litmus, and thinks it probable that they contain gallic acid in considerable quantities; the tincture of the fresh leaves being decidedly acid and astringent, and giving a deep bluish-black colour with a persalt of iron, which is in great measure discharged by a heat of 212° F. (*Am. Journ. of Pharm.*, Jan. 1866, p. 38.)

Liquidambar Altingia is said to exude a balsam in the Tennasserim Provinces of India, somewhat resembling liquid storax. (See *Pharm. Journ.*, viii. 243.) W.

LITHOSPERMUM OFFICINALE. *Gromwell. Milium Solis.* A European perennial, the seeds of which are ovate, of a grayish-white or pearl colour, shining, rather larger than millet seeds, and of a stony hardness, from which the generic name of the plant originated. From an opinion formerly prevalent, that nature indicates remedies adapted to certain diseases by some resemblance between the remedy and the character of the complaint or of the part affected, the seeds of this plant were applied to the treatment of calculous disorders; and they retained their ground in the estimation of physicians as a diuretic, useful in complaints of the urinary passages, long after the fanciful notion in which their use originated had been abandoned. But they are at present considered nearly inert, and are not employed. W.

LITMUS. Lacmus. Ed. *Turnsole. Tournesol, Orseille*, Fr. This is a peculiar colouring matter derived from Roccella tinctoria and other lichens. Three purple or blue colouring substances are known in commerce, obtained from lichenous plants. They are called severally *litmus, orchil*, and *cudbear*. The lichens employed are different species of *Roccella, Lecanora, Variolaria*, and others. They grow on alpine or maritime rocks, in various parts of the world, and for commercial purposes are collected chiefly upon the European and African coasts, and the neighbouring islands, as the Azores, Madeira, Canaries, and Cape de Verdes. The particular species most employed are probably *Lecanora tartarea* or *Tartarean moss*, growing in the North of Europe, and *Roccella tinctoria* or *orchilla weed*, which abounds upon the African and insular coasts, and is called commercially, in common with other species of the same genus, *Angola weed, Canary weed*, &c., according to the place from which it may be brought.

The principles in these plants upon which their valuable properties depend, are themselves colourless, and yield colouring substances by the reaction of water, air, and ammonia. They are generally acids, and are named *lecanoric, orsellic, erythric*, &c., according to their use or origin. What is the exact chemical change by which the colouring matters are developed is not determined; but the original body, in some instances at least, undergoes a series of changes, before the ultimate result is obtained. Dr. Stenhouse proposes that the principles should be extracted from the plants at their place of collection, so as to diminish the cost of carriage. For this purpose the lichens, having been finely divided, are to be macerated with milk of lime, the infusion thus obtained to be precipitated with muriatic or acetic acid, and the precipitate to be dried with a gentle heat. Almost the whole of the colouring principles are thus extracted, and obtained in a small bulk. To test the value of the plants as dye-stuffs, they may be macerated in a weak solution of ammonia, or a solution of hypochlorite of lime may be added to their alcoholic tincture. In the former case, a rich violet-red colour is produced; in the latter, a deep blood-red colour instantly appears, but soon fades. All the three colouring substances above referred to may be obtained from the same plant.

Lacmus or *litmus* is prepared chiefly if not exclusively in Holland. The process consists in macerating the coarsely powdered lichens, in wooden vessels under shelter, for several weeks, with occasional agitation, in a mixture of urine, lime, and potash or soda. A fermentation ensues, and the mass, becoming first red and ultimately blue, is after the last change removed, mixed with calcareous or siliceous matter to give it consistence, and with indigo to deepen the colour, and then introduced into small moulds, where it hardens. It comes to us in rectangular cakes, from a quarter of an inch to an inch in length, light, friable, finely granular, of an indigo-blue or deep-violet colour, and scattered over with white saline points. It has the combined odour of indigo and violets, tinges the saliva of a deep-blue, and is somewhat pungent and saline to the taste. From most vegetable blues it differs in not being rendered green by alkalies. It is *reddened by acids*, and restored to its original blue colour by *alkalies*.

Its chief use in medicine is as a test of acids and alkalies. For this purpose it is employed either in infusion, or in the form of litmus-paper. The infusion, usually called *tincture of litmus*, may be made in the proportion of one part of litmus to twenty of distilled water, and two parts of alcohol may be added to preserve it. *Litmus-paper* is prepared by first forming a strong clear infusion with one part of litmus to four of water,

and dipping slips of white unsized paper into it, or applying it by a brush to one surface only of the paper. The paper should then be carefully dried, and kept in well-stopped vessels, from which the light is excluded. It should have a uniform blue or slightly purple colour, neither very light nor very dark. As a test for alkalies, the paper may be stained with an infusion of litmus previously reddened by an acid. The following method of preparing litmus-paper is given in *Les Mondes*. Digest for some time 20 grammes of litmus in 100 cubic centimetres of water, shake sometimes, and filter. To the filtered liquid add a slight excess of nitric acid, and boil; and then exactly neutralize with potassa. Now make a weak solution of gelatin by boiling one part of ichthyocolla in 6 parts of water; immerse in this solution some white unsized paper, and afterwards hang it up to dry; then colour one side of it with the solution of litmus. (*Journ. de Pharm.*, Sept. 1868, p. 224.) By gas-light it is said that the change of colour cannot be determined by the eye exactly, as the blue of litmus becomes mauve; but this may be obviated by watching the process through a green glass, by which the faintest trace of blue becomes discernible. (*Pharm. Journ.*, 2d ser., vi. 479.)

M. de Luynes has succeeded in procuring a colouring matter from *orcine*, a peculiar saccharine principle extracted by Robiquet from the *Variolaria dealbata*, a lichenous plant inhabiting the Pyrenees. (Guibourt, *Hist. Nat. des Drogues Simp.*, 4e ed., ii. 80.) A fine violet colouring matter had been previously prepared from orcine, by the action of ammonia and oxygen, denominated *orceine* (*Ibid.*); but M. de Luynes was the first to prepare litmus from it. The process consists in mixing, in an imperfectly stopped matrass, orcine with 25 times its weight of crystallized carbonate of soda, and 5 times its weight of water, to which a little water of ammonia has been added, at most equal in quantity to the orcine. The whole is heated to between 140° and 170° F., for five or six days, care being taken to agitate the mixture from time to time. The resulting liquid, of a deep-violet blue, is diluted with water, and saturated by a slight excess of muriatic acid, which precipitates the colouring matter. Thus prepared, litmus is in little irregular lumps, possessing the iris-like and metallic reflections of most colouring matter; very slightly soluble in cold water, to which it imparts a vinous tint, becoming of an onion-skin colour with acids, and a violet-blue with alkalies; very slightly soluble also in alcohol, which it renders yellow. Its alcoholic solution, diluted with water, is an extremely sensitive agent for the detection of the least traces of alkaline substances. By adding to it a very minute quantity of potassa, a blue liquid is obtained, which is affected by acids in the same manner as ordinary tincture of litmus. (*Journ. de Pharm.*, 4e sér., i. 141.)

Orchil or *archil*, as prepared in England, is in the form of a thickish liquid, of a deep reddish-purple colour, but varying in the tint, being in one variety redder than in another. The odour is ammoniacal. It is made by macerating lichens in a covered wooden vessel, with an ammoniacal liquor, either consisting of stale urine and lime, or prepared by distilling an impure salt of ammonia with lime and water. (*Pereira.*) It is occasionally adulterated with the extracts of coloured woods, as logwood, sappan-wood, &c. A mode of detecting these adulterations is given by Mr. F. Leeshing in the *Chemical Gazette* of June 1, 1855 (p. 219).

Cudbear is in the form of a purplish-red powder. It is procured in the same manner as orchil; but the mixture, after the development of the colour, is dried and pulverized.

The point in which the preparation of these colouring substances differs from that of litmus appears to be, that potash or soda is added, in the latter, to the ammoniacal liquid used. Orchil and cudbear are employed as dye-stuffs, and sometimes, in like manner with litmus, as a test of acids and alkalies. W.

LOLIUM TEMULENTUM. *Darnel. Ivraie*, Fr. One of the Graminaceæ or grasses, belonging to the Linnæan class and order Triandria Digynia, indigenous in the old world, but introduced into the U. States, and owing its chief importance to the circumstance that it is apt to grow among wheat and other grains, and thus sophisticate the product with its seeds. From ancient times, these have been supposed to be deleterious to the human system, producing symptoms analogous to intoxication from alcoholic drinks, whence the plant derived its specific name of *Temulentum*, and the French name of *ivraie*. The seeds have a sweetish taste, and are said to contain gluten, starch, and sugar; and there is nothing in their sensible properties which would suggest the idea that they might be poisonous. Indeed, De Candolle states that they are often eaten in bread without inconvenience; and that a beer into which they enter as an ingredient is drank with impunity. (*Mérat et De Lens*, iv. 141.) The testimony, however, to the fact, that they have a narcotic effect on the system, evincing itself by vertigo, dizziness, headache, sleepiness, and a species of drunkenness, is too strong to be resisted; though very few instances, so far as we know, have been recorded of positively fatal effects from their use. MM. Rivière and Maizière have each recorded a fatal case, which occurred in peasants who had for several days lived upon bread, consisting to the extent of two-thirds or five-sixths of darnel. (*Journ. de Pharm.*, Oct. 1863, p. 280.) Though thus acting on man, dogs, sheep, and horses, the seeds are said to be wholly innoxious to hogs, cows, and ducks; and poultry have even been fattened by them. The remedy, in case of poisoning, would be as soon as possible to evacuate the stomach. Lindley states that this is the only one of the grasses which has been satisfactorily proved to have deleterious properties. (*Med. and Economic*

Bot., p. 27.) Two analyses have recently been made of the seeds. One, by MM. Filhol and Baillett, gives as their constituents, about 50 per cent. of starch; a thick, almost solid green oil, consisting of a portion saponifiable and another not so, the latter soft, orange coloured, insoluble in water, very soluble in alcohol, ether, and sulphuret of carbon, producing tremulousness when swallowed, but without any symptoms of narcotism, and capable of causing death in animals; sugar; dextrin; albumen; and a substance hitherto observable only in the form of extractive, soluble in water and alcohol, and acting on animals as a narcotic. The second examination was made by Ludwig and Stahl, who, besides cellulose, gluten, and starch, found 1. a neutral fatty matter burning with smoke; 2. an oily acid, burning without smoke, and precipitated from its alcoholic solution by acetate of lead; 3. an acrid oil, burning with smoke and an odour of incense; 4. a fixed oil, acrid and bitter, saponifiable, and after being saponified, yielding, by precipitation with muriatic acid, a white, rancid matter, volatilizable with watery vapour; and a portion of this substance is contained in the seeds as a soap soluble in water. All the above principles, in the free state, are soluble only in alcohol and ether. In addition, there were, 5. a substance soluble in water, producing a viscid mass, of an acrid and bitter taste, and transformable into sugar and volatile acids by boiling in contact with dilute sulphuric acid; 6. uncrystallizable sugar; 7. tannic acid, producing a green colour with the salts of iron, and yielding sugar with dilute sulphuric acid; 8. an acid resembling the metapectic; 9. sulphate of potassa; 10. resinous substances. The authors consider the activity of the seeds to reside in the acrid oils, and the bitter principle mentioned in no. 5. (*Ann. de Thérap.*, 1866, p. 64.) W.

LONICERA CAPRIFOLIUM. *Honeysuckle.* This ornament of our gardens is a native of the South of Europe. Its sweet-scented flowers are sometimes used in perfumery; and a syrup prepared from them has been given in asthma and other pectoral affections. The expressed juice of the plant has been recommended for the stings of bees, being rubbed directly on the injured spot. The fruit of all the species of Lonicera is said to be emetic and cathartic. (*Mérat et De Lens.*) W.

LYCIUM BARBARUM. *Matrimony Vine.* The genus Lycium belongs to the Linnæan class and order Pentandria Monogynia and to the natural order Solanaceæ. Different species have been used in various parts of the world in reference to supposed medical virtues. Lycium barbarum, which is indigenous in the South of Europe and in Asia, is a thorny shrub, with long flexible branches, and is cultivated for hedges and arbours. The leaves and stems were examined chemically by Drs. Husemann and Marme, who succeeded in extracting from them an alkaloid by means of phosphomolybdate of soda. For the mode of proceeding, as well as for the method of preparing the phosphomolybdate used by them, the reader is referred to the *American Journal of Pharmacy* (May, 1864, p. 226). The alkaloid, which they name *lycin* (*lycina*, or more properly, *lycia*), is characterized by its strong affinity for water, which causes it to deliquesce in a few minutes after exposure, and renders it very soluble in that liquid. It is also readily soluble in alcohol, but nearly insoluble in ether. It is crystallizable, of a sharp but not bitter taste, and forms crystallizable salts with the acids. The young shoots of one of the species of Lycium are eaten in Spain as asparagus, and its leaves as salad; and the aborigines of New Granada use another species against erysipelas. The leaves of L. barbarum, as well as the fruit, are said to be used by the physicians of Japan. (*Mérat et De Lens.*) W.

LYTHRUM SALICARIA. *Loosestrife. Purple Willow-herb.* This is an elegant perennial plant, two or three feet high, with an erect, quadrangular, hexagonal, downy, herbaceous stem, bearing opposite, ternate, sessile, lanceolate leaves, cordate at the base, and downy on the under surface and at the margin. The flowers are axillary, forming a leafy verticillate spike. The calyx is red, with unequal segments, the petals purple and undulate, the fruit a small elliptical capsule. The plant grows wild in all parts of Europe, and is found in New England and Canada. It prefers meadows, swamps, and the banks of streams, which it adorns in July and August with its showy purple flowers. The whole herbaceous part is medicinal, and is dried for use. In this state it is inodorous, and has an herbaceous, somewhat astringent taste. It renders boiling water very mucilaginous, and its decoction is blackened by the sulphate of iron. Loosestrife is demulcent and astringent, and may be advantageously given in diarrhœa and chronic dysentery, after due preparation by evacuating treatment. It has long been used in Ireland in these complaints, and is said to be a popular remedy in Sweden. The dose of the powdered herb is about a drachm two or three times a day. A decoction of the root, prepared by boiling an ounce in a pint of water, may be given in the dose of two fluidounces. W.

MALAMBO OR MATIAS BARK. A bark received from South America by Dr. Alex. Ure, under the name of *matias bark*, was found to have the characters of the *malambo bark*, which is held in high esteem in New Granada where it is produced, and has been long known to the French pharmacologists. Though conjecturally ascribed by some to a Drimys, and by others to a Croton, its botanical source was unknown till within a few years. It has been ascertained by H. Karston, of Berlin, to be derived from a hitherto undescribed species of Croton, which he names *Croton Malambo*, and which is described

in his work entitled "*Floræ Columbiæ Terrarumque adjacentium Specimina Selecta.*" This is a small tree or shrub, growing on the coast of Venezuela and New Granada. (*Pharm. Journ.*, Dec. 1859, p. 321.) The bark is described by Dr. Ure as being three or four lines thick, brittle though somewhat fibrous, of a brown colour, and covered with an ash-coloured tuberculous epidermis. It has an aromatic odour, and a bitter pungent taste, and yields these properties to water and alcohol. Its active ingredients appear to be a volatile oil, and a bitter extractive matter. According to Dr. Mackay, it has been used successfully in intermittents, convalescence from continued fever, hemicrania, dyspepsia, and other cases in which tonic remedies are useful, and also as an adjuvant to diuretics. It is probably nothing more than an aromatic tonic. Dr. Ure has administered it with good effect as a substitute for Peruvian bark. (*Pharm. Journ.*, iii. 169.)

Under the name of *Winter's bark*, a considerable quantity of bark was some time since imported into the United States from South America, which Mr. E. S. Wayne, of Cincinnati, has identified with the malambo bark above described, having found it to correspond with that product both in sensible characters and composition. (*Am. Journ. of Pharm.*, xxix. 1.) We can confirm this decision of Mr. Wayne; as a specimen in our possession answers precisely to the description given by Dr. Ure. The malambo bark, analyzed by Cadet de Gassicourt, yielded volatile oil, bitter resin, and extractive; but no tannic nor gallic acid, and no alkaloid; and the same was the case with the so-called Winter's bark examined by Mr. Wayne. (*Ibid.*) The same bark has been analyzed by Mr. F. B. Dancy, who found in it volatile oil, gum, starch, albumen, resin, extractive, fixed oil, wax, and several inorganic substances. (*Ibid.*, p. 219.) W.

MALVA SYLVESTRIS. *Common Mallow.* This herb was recognised by the Edinburgh College, but has been discarded by the British Council, and is no longer officinal. It belongs to the Linnæan class and order Monadelphia Polyandria, and the natural family Malvaceæ. The following is its essential generic character. "*Calyx* double, the exterior three-leaved. *Capsules* very many, one-seeded." (*Willd.*) It is a perennial, herbaceous plant, with a round, hairy, branching, usually erect stem, from one to three feet high, bearing alternate, petiolate, cordate, roughish leaves, which are divided into five or seven crenate lobes, and on the upper part of the stem are almost palmate. The flowers are large, purplish, and placed, from three to five together, at the axils of the leaves, upon long slender peduncles, which, as well as the petioles, are pubescent. The petals are five, inversely cordate, and three times as long as the calyx. The capsules are disposed compactly in a circular form. This species of mallow is a native of Europe, growing abundantly on waste grounds and by the way-sides, and flowering from May to August. It is sometimes cultivated in our gardens. Other species, indigenous or naturalized in this country, are possessed of the same properties, which are in fact common to the genus. *Malva rotundifolia* is one of the most common, and may be substituted for *M. sylvestris*. The herb and flowers have a weak, herbaceous, slimy taste, without odour. They abound in mucilage, which they readily impart to water; and the solution is precipitated by acetate of lead. The infusion and tincture of the flowers are blue, and serve as a test of acids and alkalies, being reddened by the former, and rendered green by the latter. The roots and seeds also are mucilaginous. Common mallow is emollient and demulcent. The infusion and decoction are sometimes employed in catarrhal, dysenteric, and nephritic complaints; and are applicable to all other cases which call for the use of mucilaginous liquids. They are also used as an emollient injection; and the fresh plant forms a good suppurative or relaxing cataplasm in external inflammation. It was formerly among the culinary herbs. W.

MANDRAGORA OFFICINALIS. *Atropa Mandragora.* Linn. *Mandrake. Mandragora.* A perennial European plant, with spindle-shaped root, which is often forked beneath, and is therefore compared, in shape, to the human figure. In former times this root was supposed to possess magical virtues, and was used as an amulet to promote fecundity, &c.; and the superstition is still cherished by the vulgar in some parts of Europe. The plant is a poisonous narcotic, somewhat similar in its properties to belladonna, to which it is botanically allied. It was much used by the ancients with a view to its narcotic effects; and the root has been recommended by some eminent modern physicians, as an external application to scrofulous, scirrhous, and syphilitic tumours. It is said to have been used by the ancients as an anæsthetic agent before surgical operations. (*Journ. de Pharm.*, xv. 290.) It is unknown as a remedy in the United States. W.

MANGANESE. *Manganesium.* This metal and its compounds with oxygen (three regular oxides and two acids) have been already described. (See *Manganesii Oxidum Nigrum.*) Several of its combinations have been proposed as medicines, and the therapeutic trials, thus far made with them, place them alongside of those of iron as tonic and anti-anemic remedies. It will be recollected that manganese as well as iron is always present, in minute proportion, in healthy blood, and has been detected in various solids and fluids of the body. (See *page* 543.) According to an analysis by M. Burin-Dubuisson, the amount of manganese in the blood corpuscles is about one-twentieth that of the iron. It is stated, as an advantage of the preparations of manganese, that they may be prescribed in conjunction with tannic acid and the various astrin gent medicines, which are

all incompatible with the preparations of iron. Of the oxides of manganese, the *protoxide* only is strongly salifiable; and this is the oxide present in the ordinary salts of the metal. It may be obtained by precipitation, as a white hydrate, from any of the soluble salts of manganese by the addition of a caustic alkali. This, according to M. Hannon, is a good medicinal preparation; but a strong objection to it is that it rapidly absorbs oxygen, and passes to the state of the brown hydrated sesquioxide. The officinal deutoxide (native black oxide) is described at *page* 543, where its medical properties are also noticed. The *sulphate of manganese*, having been adopted as an officinal medicine at the late revision of the U. S. Pharmacopœia, is also described in the first part of this work (*page* 544). The same is the case with *hypermanganate* or *permanganate of potassa*, which is fully treated of under the head of *Potassæ Permanganas* (page 708).

Iodide of Manganese. This iodide may be administered in syrup or pill. Professor Procter has proposed the following formula for the *syrup*. Dissolve *sixteen drachms* of sulphate of manganese, and *nineteen drachms* of iodide of potassium, separately, in *three fluidounces* of water, each portion of water being previously sweetened with *two drachms* of syrup. Mix the solutions in a glass-stoppered bottle, and, when the crystals of sulphate of potassa have ceased to precipitate, throw the liquor on a strainer of fine muslin, and allow it to filter into a pint bottle, containing *twelve ounces* of powdered sugar. When the solution has ceased to pass, wash the filter with a little sweetened water, and add sufficient of that liquid to make the whole measure *a pint*. Lastly, agitate the liquid until the sugar is dissolved. Prof. Procter states that this syrup contains about a drachm of iodide of manganese in each fluidounce, and corresponds in strength to the officinal solution of iodide of iron. The small proportion of sulphate of potassa which remains dissolved in the syrup, does not interfere with its medicinal efficacy. The dose is from ten to thirty drops, repeated several times a day. (*Am. Journ. of Pharm.*, Oct. 1850.) M. Hannon makes a *pill of iodide of manganese* by double decomposition between equal weights of iodide of potassium and crystallized sulphate of manganese. The salts are perfectly dried, accurately mixed in powder, and then rubbed up with honey, so as to reduce the whole to a pilular mass, which may be divided into four-grain pills. Assuming that the honey added compensates for the loss of water in drying, each pill will consist of about two grains of iodide of manganese, one of sulphate of potassa, and one of honey, and sulphate of manganese in excess. The dose is one pill daily, gradually increased to six. According to M. Hannon, iodide of manganese is particularly useful in the anæmia attendant on scrofula, phthisis, and cancer, and in syphilitic cachexy. Given in conjunction with cinchona, it rapidly removes the enlargement of the spleen often following protracted fevers.

Carbonate of Manganese. This salt may be obtained by the following formula, which is that of M. Hannon, accommodated to the weights and measures of the U. S. Pharmacopœia. Dissolve *seventeen ounces* of crystallized sulphate of manganese, and *nineteen ounces* of carbonate of soda, separately, in two pints of water, *a fluidounce* of syrup having been previously added to each pint; and, having mixed the solutions in a well-stopped bottle, allow the precipitate to subside. Decant the supernatant liquid, wash the precipitate with sweetened water, allow it to drain from a cloth saturated with syrup, express, mix with *ten ounces* of honey, and evaporate rapidly to form a pilular mass, which is to be divided into four-grain pills. By a double decomposition between the sulphate of manganese and carbonate of soda, carbonate of manganese is precipitated, and sulphate of soda remains in solution. The sulphate is washed away, and the carbonate is brought to a pilular consistence with honey, which, together with the syrup, prevents the protoxide of manganese in the pill from rising to a higher stage of oxidation. The dose is from two to ten pills daily. Carbonate of manganese was tried by M. Hannon as a medicine on himself. After its use for fifteen days he found his appetite improved, and his pulse increased in force; and he experienced a feeling of sanguineous plethora. He afterwards exhibited the remedy in several anemic cases, with the effect of exciting the functions to a more healthy action, increasing the strength and improving the blood.

Phosphate, *tartrate*, and *malate of manganese* have also been proposed by M. Hannon as useful remedies. The phosphate is prepared by double decomposition between sulphate of manganese and phosphate of soda. A *syrup of phosphate of manganese* has been made by Mr. T. S. Wiegand, of this city. (See his formula in the *Am. Journ. of Pharm.* for July, 1854.) Dr. Simpson, of Edinburgh, informed one of the authors that a syrup made with two grains of phosphate of iron and one grain of the phosphate of manganese in a fluidrachm of syrup, was much and advantageously used by himself and others in Edinburgh. This may be easily prepared by adding to the two ingredients mentioned five grains of glacial phosphoric acid for each grain of the phosphate of iron. (*Pharm. Journ.*, Nov. 1859, p. 288.) *Lactate of manganese* has been given, associated with lactate of iron, in chlorosis, in the dose of a grain, increased to five grains.

Ferro-manganic Preparations. M. Hannon conceives that manganese is peculiarly suited to the treatment of anemic cases in which iron has failed, or acts very slowly; but, instead of passing at once from the use of iron to that of manganese, he prefers to give intermediately a mixture of the two metals. For this purpose he recommends the following formula. Take of crystallized sulphate of iron *six drachms and a half;* crystallized

sulphate of manganese *two drachms;* carbonate of soda *nine drachms;* honey *five drachms.* Rub together, and with syrup make a mass, to be divided into four-grain pills. In this pill both the metals are present as carbonates; and, as the sulphate of soda is not washed away, it contains that salt also. The dose is from two to ten pills daily. (See the paper of M. Hannon, *Journ. de Pharm.*, 3e sér., xvi. 41 and 189; also a note of the favourable results obtained by M. Pétrequin, of Lyons, *Ibid.*, xvi. 381.) Further experience has confirmed the favourable opinion of M. Pétrequin in relation to the therapeutic value of the ferro-manganic preparations. A number of formulas have been devised by M. Burin-Dubuisson, of Lyons, for making them, containing the metals variously combined; but the most important of them is the *syrup of iodide of iron and manganese*, for the preparation of which we prefer the following formula by Prof. Procter. Take of iodide of potassium 1000 grains; sulphate of protoxide of iron 630; sulphate of protoxide of manganese 210; iron filings 100; sugar, in coarse powder, 4800. Powder the iodide and sulphates separately, and, having mixed them with the filings, add half a fluidounce of distilled water, and triturate to a uniform paste. Then add another half fluidounce of distilled water to the paste, and triturate again; and, after an interval of fifteen minutes, add a third half fluidounce, and mix. Next transfer the magma of salts to a moistened filter, supported on a funnel, and allow them to drain into a bottle, holding a little more than twelve fluidounces, and containing the sugar. After they have drained, add cold boiled water by small portions at a time, until the solution of the iodides has been displaced and washed from the crystalline magma of sulphate of potassa. Finally, add sufficient cold boiled water to make the whole measure *twelve fluidounces*. The object of the iron is to prevent the liberation of iodine. This syrup has a very pale straw colour. It contains a little sulphate of potassa, which does not injure it as a therapeutic agent. If the salts have not been all decomposed during their reaction, it will be greenish. Each fluidounce contains 50 grains of the mixed iodides, in the proportion of 3 parts of iodide of iron to 1 of iodide of manganese. The dose is from ten drops to half a fluidrachm. (*Am. Journ. of Pharm.*, May, 1853, p. 198.) Syrup of iodide of iron and manganese is considered by M. Pétrequin to be particularly suited to the treatment of anæmia, resulting from obstinate intermittent fevers, prolonged suppuration, and scrofulous, syphilitic, and cancerous affections.

Dr. T. S. Speer, of Cheltenham, in imitation of the practice of M. Hannon and M. Pétrequin, has employed the combined carbonates of iron and manganese with excellent effects; but, instead of using the carbonate in pill, protected by honey and syrup, as M. Hannon has done, he prefers a saccharine carbonate of the two metals, in imitation of the London saccharine carbonate of iron, made by the following formula. Dissolve *three ounces and one drachm* of sulphate of iron, *one ounce and one scruple* of sulphate of manganese, and *five ounces* of carbonate of soda, each, in *thirty Imperial fluidounces* of water, and thoroughly mix the solutions. Collect the precipitated carbonates on a cloth filter, and wash them immediately with cold water, to separate the sulphate of soda. Then press out as much water as possible, and, without delay, triturate the pulp with *two and a half ounces* of finely powdered sugar. Lastly, dry the mixture at a temperature not exceeding 120°. The *saccharine carbonate of iron and manganese*, as thus prepared, is a reddish-brown powder, devoid of all taste, except that imparted by the sugar. The dose is five grains, gradually increased to a scruple, three times a day, given with the meals, or immediately after them. (See *Am. Journ. of Pharm.*, March, 1854, p. 127; from *Med. Times and Gaz.*) B.

MATA. This name is given, in New Mexico, to an herb much used in that region as an addition to tobacco in smoking. Attention has been called to it by Prof. E. S. Wayne, in a brief communication to the *American Pharmaceutical Association*, published in their *Proceedings* for 1867. It is said, when burning, to have an odour like that of the Tonka-bean, and, when smoked with tobacco, to correct the extremely disagreeable smell imparted by this to the clothing and apartments. From imperfect specimens of the plant raised by Prof. Wayne from seeds which had come into his possession, and sent to Prof. Maisch, it is supposed to be a Eupatorium, probably the *E. incarnatum* of Walter, which is indigenous in Texas, and with the description of which the specimens closely corresponded. (*Am. Journ. of Pharm.*, March, 1868, p. 122.) The name Mata must not be confounded with mate, the name given by the people of the La Plata to the famous Paraguay tea, the product of *Ilex Paraguaiensis*. (See *page* 1616.) W.

MEAT BISCUIT. This alimentary substance, containing much nutriment in a small bulk, is the invention of Mr. Gail Borden, jun., of Texas. It is made by mixing a concentrated fluid extract of flesh, strained through wire-cloth, and freed from fat, with good wheat flour, or other meal, and baking the dough into a biscuit, which must be preserved, in mass or coarse powder, free from moisture, in gutta-percha bags, or air-tight casks or cases. To make the dough, about two parts of the extract are mixed with three of the flour; and about 20 per cent. is lost in baking. The extract contains the soluble ingredients of the flesh, not coagulable by heat; namely, gelatin, kreatin, kreatinin, the phosphoric, lactic, and inosinic acids, and certain salts. Of course, it contains no albumen nor fibrin, unless in some altered state in which they are rendered soluble at a boiling temperature. In this nutritious biscuit, the absence of albumen and fibrin is

supposed to be supplied by the gluten of the flour. To prepare a pint of palatable soup, an ounce of the powdered biscuit, first made into a thin paste with cold water, is added, with constant stirring, to sufficient boiling water, and the whole boiled for twenty minutes. Salt and pepper are then added to suit the taste. The meat biscuit forms an important resource in all cases in which food must be carried on long journeys for daily consumption. B.

Borden's Extract of Beef. This, which is also a preparation of Mr. Borden's, might perhaps have been more appropriately referred to under *Extractum Carnis* (see *page* 1593); but convenience has induced us to place it here in connection with the meat biscuit of that manufacturer. It is prepared in Illinois, in consequence of the abundance, in that State, of the beeves best suited to the purpose. It appears to be prepared essentially as the extracts of beef already noticed, only that the evaporation, which is conducted in vacuo, is carried to dryness. It consists exclusively of the soluble ingredients of the flesh, without addition, even of common salt or other condiment; and, as it is in the process of extraction exposed to a sufficient heat to cook it thoroughly, it requires no further application of heat to fit it for use; all that is necessary being hot water to dissolve it. As it is in the dry solid state, it does not require cans for its preservation; and is kept for sale in the form of packages of different sizes. One pound of it represents 20 pounds of beef. Being free from mustiness or other offensive smell or taste, it may be made immediately into soup of any desired strength, either for the sick or well. From one-half of an ounce to an ounce cut into small pieces, and stirred with a quart of hot water till perfectly dissolved, with salt and black pepper or such other flavouring material as may be required, will form beef soup. If peas, beans, or other leguminous fruit, with fresh vegetables, be required, these should first be made into a soup, and the extract afterwards added in due proportion while the liquid is still hot. A preparation equivalent to essence of beef may be made by dissolving two-thirds of an ounce in a pint of boiling hot water. W.

Preserved Meat-juice is a nutritive liquid, prepared by Mr. Gillon, a manufacturer of preserved meats, at Leith, in Scotland. The process for making it, as described by Prof. Christison, is as follows. A number of cylindrical cases of tinned iron, each containing six pounds and a half of beef, and closed by soldering with a lid, having a hole half an inch wide in the middle of it, are placed in an iron cylinder, surrounded with an iron jacket so as to leave an interstice, and heated by steam, admitted into the interstice, to the temperature of 220° for about three hours. The cases are then withdrawn, and the juice is poured out, amounting to a few ounces for each case, and, after cooling, is entirely freed from fat. It is next poured into four-ounce tin cases, which are closed as before, with a small aperture in the lid secured with solder. These are subjected to a temperature of 220° in a chloride of calcium bath for some time, and, when removed from the bath, are opened by melting the solder which secures the aperture; whereupon steam rushes out, and carries with it the air which may have collected in the upper part of the case. As soon as the gaseous matter ceases to be expelled, the aperture is resoldered. The process of heating in the bath, tapping, and resoldering is then repeated; and the cases are finally painted, to preserve them from rust. Dr. Christison states that he has repeatedly opened cases, eighteen months in his possession, and found the contents to possess the rich delicate aroma and taste of fresh beef-juice. Mr. Gillon's meat-juice contains only 6·5 per cent. of solids, consisting of osmazome, with the salts, and sapid and odorous principles of meat. It contains neither fibrin, albumen, nor gelatin. It may be taken in the concentrated form, but is generally best diluted. The contents of a case (four ounces) will make sixteen ounces of strong beef tea, by the addition of the requisite quantity of boiling water. (See *Med. Exam.*, March, 1855.) B.

Flour of Meat. Dr. A. H. Hassal, of London, has given this name to a preparation of meat, which concentrates within a smaller space, and more completely represents the virtues of meat, than any other preparation of which we have seen an account. Of the different forms of extract and essence of meat, almost all have this great deficiency that, while they contain the stimulating and effete constituents of the meat, they are destitute of the fibrin and albumen, which are probably its most nutritious ingredients; and absolutely all are without the fibrin. His method consists in drying the meat, at a temperature generally below that necessary for coagulating albumen, so as to deprive it of all its water, without removing any of its essential constituents, perhaps in vacuo, and then grinding it into a *very fine powder*. When made from beef, the powder is of a light-brown colour and very agreeable taste; and one pound represents four pounds of flesh, or six pounds of the leanest joints not deprived of bone and fat. In a few words, Dr. Hassal speaks of it as 1. useful for the speedy preparation of beef tea; 2. with vegetables and flavouring substances for quickly making soups; 3. in forming, when combined with farinaceous matter, a nutritious food, well adapted for children, dyspeptics, and invalids; 4. for making, by mixture with cocoa, a nutritious breakfast drink; and 5. for forming meat biscuit. Dr. Hassal has here omitted, what appears to us to be its highest recommendation, that it is an excellent article of diet for the old and toothless, who cannot sufficiently comminute meats for the purpose of easy digestion. (*Lancet*, Feb. 17, 1866, p. 184.) In a subsequent communication to the same journal

Dr. Hassal recognises this as among its useful applications. He speaks also of its being retained by the stomach when meat in its ordinary forms is rejected, of its applicability to cases in which it is necessary to inject nutritive food into the stomach or the rectum, and of its special usefulness as an article of food in dyspepsia, in diabetes, in the weakness following parturition, and in low forms of fever. Dr. Hassal says that it is finer even than wheat flour. (*Ibid.*, April 28, 1866, p. 469.)

Raw Meat has been recommended as an article of diet for consumptive patients, and especially for scrofulous children, and in other cachectic cases, and is asserted to have proved highly useful. It was brought into notice by M. Fuster, of Montpellier, France. The following formula is recommended by M. Reveil. Take of fillet of beef 100 grammes, deprive it carefully of all fatty and membranous matter, cut it up finely, beat it in a mortar, and add of powdered sugar 20 grammes, chloride of sodium 1·5 grammes, chloride of potassium half a gramme, and powdered black pepper one-fifth of a gramme. The mixture is to be taken in teaspoonful doses through the day. (*Ann. de Thérap.*, 1866, p. 145.) W.

Pemmican is an alimentary substance, containing much nutriment in a small bulk, which is used by fur traders and others, as their exclusive food, on long journeys in the northwest of this continent. It is made, according to Dr. C. C. Keeney, U. S. Army, by mixing equal weights of buffalo meat and buffalo tallow. The meat, thoroughly dried in the sun, is reduced to powder, and the tallow in the melted state is added to it, and the whole well stirred. The melted mixture is then poured into sacks of untanned buffalo hide, capable of containing from twenty to forty pounds. No salt is used, and yet the mixture keeps perfectly well. (*Med. Statistics, U. S. Army*, p. 56.) B.

MEDEOLA VIRGINICA. *Gyromia Virginica.* Nuttall. *Indian Cucumber.* An indigenous perennial herb, growing in all parts of the United States. The root, which in shape and flavour bears a strong resemblance to a small cucumber, is said by Pursh to be eaten by the Indians. According to the late Professor Barton, it has been thought useful in dropsies, and probably possesses diuretic properties. It is figured and described by Dr. William P. C. Barton in his Medical Botany. W.

MELILOTUS OFFICINALIS. *Melilot.* An annual or biennial plant, indigenous in Europe, and growing also in this country. We have two varieties, one with yellow, the other with white flowers, which are considered by some as distinct species. The plant, when in flower, has a peculiar sweet odour, which, by drying, becomes stronger and more agreeable, somewhat like that of the Tonka-bean. Indeed, according to M. Guillemette, the odorous principle of the two substances is identical. (*Journ. de Pharm.*, xxi. 172.) The taste of melilot is slightly bitterish. It has little medical power, and, though formerly recommended in various diseases, is at present not employed internally. As a local application, it is used, in decoction or cataplasm, in moderate inflammations, though probably with little other advantage than such as results from the combination of warmth and moisture. W.

MENISPERMUM CANADENSE. *Moonseed. Yellow Parilla.* This is a climbing plant, growing in various parts of the United States, from the northern boundary to the Gulf of Mexico. It is described in the Flora of North America by Torrey and Gray (i. 48), and in Gray's *Manual of the Botany of the U. States* (p. 18). The root or rhizoma is long, of a yellow colour, and a bitter taste. Considerable quantities of a root were some time since brought to the market of Philadelphia from New Orleans, and offered for sale as *Texas sarsaparilla*. This was satisfactorily shown by Prof. Robert P. Thomas to be the root of *Menispermum Canadense*. (*Am. Journ. of Pharm.*, xxvii. 7.) In an unpublished inaugural dissertation by Dr. Geo. F. Terrell (Feb. 1844), it is stated that the root of this plant is considerably employed in Virginia, both in domestic practice and by physicians, as a substitute for sarsaparilla, in scrofulous affections. It has a bitter taste, and is said to be a gently stimulating tonic. Its natural affinity with the columbo plant, both belonging to the family of Menispermaceæ, and the sensible properties of its root, naturally suggested that this might contain the same or similar active principles with columbo; and Mr. Maisch, in a chemical examination, determined that, among its constituents, are berberina in small proportion, and a white or colourless alkaloid in larger quantity, which has an alkaline reaction on litmus and turmeric paper, is precipitated by tannin, phosphomolybdic acid, and iodohydrargyrate of potassium, and is soluble in ether, alcohol, and a large proportion of water. (*Am. Journ. of Pharm.*, July, 1863, p. 302.) W.

MENYANTHES TRIFOLIATA. *Buckbean. Marsh Trefoil.* The leaves of this plant were recognised in the late Edinburgh Pharmacopœia, but, having been omitted in the British, are noticed in this place, in accordance with our plan of introducing into the third part of the work all the medicines which have ceased to be officinal. Menyanthes trifoliata belongs to the Linnæan class and order Pentandria Monogynia, and the natural order Gentianaceæ, with the following generic character. "*Corolla*, hirsute. *Stigma* bifid. *Capsule* one-celled." (*Willd.*) The plant has a perennial, long, round, jointed, horizontal, branching, dark-coloured root or rhizoma, about as thick as the finger, and sending out numerous fibres from its under surface. The leaves are ternate, and upon long stalks, which proceed from the end of the root, and are furnished at their base with sheathing stipules. The leaflets are obovate, obtuse, entire or bluntly denticulate, very smooth, beautifully

green on their upper surface, and paler beneath. The flower-stalk is erect, round, smooth, from six to twelve inches high, longer than the leaves, and terminated by a conical raceme of whitish, somewhat rose-coloured flowers. The calyx is five-parted; the corolla funnel-shaped, with a short tube, and a five-cleft, revolute border, covered on the upper side with numerous long, fleshy fibres. The anthers are red and sagittate; the germ ovate, supporting a slender style longer than the stamens, and terminating in a bifid stigma. The fruit is an ovate, two-valved, one-celled capsule, containing numerous seeds. This beautiful plant is a native both of Europe and North America, growing in boggy and marshy places, always moist, and occasionally overflowed with water. It prevails, in the United States, from the northern boundary to Virginia. In this country the flowers appear in May, in England not till June or July. All parts of it are efficacious, but the leaves only were officinal.

The taste of buckbean is intensely bitter and somewhat nauseous, the odour of the leaves faint and disagreeable. Its virtues depend on a bitter principle denominated *menyanthin*, which may be obtained sufficiently pure for use by treating the spirituous extract of the plant with hydrated oxide of lead, removing the lead by hydrosulphuric acid, filtering and evaporating the liquor, exhausting the residue with alcohol, and again evaporating with a gentle heat. It has a pure bitter taste, is soluble in alcohol and water, but not in pure ether, and is chemically neuter. (*Pharm. Cent. Blatt*, A.D. 1843, p. 24.)

Medical Properties and Uses. With the ordinary properties of the bitter tonics, menyanthes unites a cathartic power, and in large doses is apt to vomit. It was formerly held in high esteem in Europe as a remedy in numerous complaints, among which were intermittents, rheumatism, scrofula, scurvy, dropsy, jaundice, and various cachectic and cutaneous affections. In most of these it was administered under a vague impression of its alterative powers. It is little employed in this country; but, as it is a native plant, and applicable to cases where a combined tonic and purgative effect is demanded, it is desirable that country practitioners should be aware of its properties. The dose of the powdered leaves or root as a tonic is from twenty to thirty grains; of an infusion, prepared with half an ounce to a pint of boiling water, from one to two fluidounces; and of the extract ten or fifteen grains, to be repeated three or four times a day. A drachm of the powder, or a gill of the strong decoction, generally purges, and often occasions vomiting. W.

MERCURIALIS ANNUA. An herbaceous European plant, of the family of Euphorbiaceæ, which has been employed, from the most ancient times, as a purgative and emmenagogue. It has also been considered by some as diuretic, and has been used in the treatment of syphilitic affections. When boiled, it loses its acrid properties, and in this condition has been used as an emollient. Another species, *M. perennis*, also a native of Europe, is ranked among poisonous plants. (*Mérat et De Lens.*) But what has recently recalled attention to the annual species is the discovery in it, by Reichardt, of a new volatile alkaloid, which he proposes to name *mercurialin* (*mercurialia*). This is a liquid, of an oily appearance, narcotic odour, and alkaline reaction; boils at 284° F.; forms salts with the acids; absorbs carbonic acid; has a strong affinity for water; on exposure to the air is changed into a resin of a buttery consistence; and is very poisonous in its action on man. For the mode of procuring it, see *Annuaire de Thérapeutique* (1864, p. 44). The existence of a volatile alkaloid in the Mercurialis suggests that other Euphorbiaceæ may owe their acrid properties to a similar constituent. W.

MESEMBRYANTHEMUM CRYSTALLINUM. *Ice-plant.* A biennial plant, growing spontaneously in the South of Europe, and cultivated as a curiosity in colder countries, by the aid of artificial warmth. The stem and under surface of the leaves are covered with crystalline drops, which give the plant the appearance of being coated with ice. The herb is without smell, and has a saline somewhat nauseous taste. It is considered demulcent and diuretic, and has been commended as a remedy in various complaints, especially those of the mucous membrane of the lungs and urinary passages. It has also been used in dropsy. The expressed juice is the form in which it has been generally employed. W.

MESENNA. *Musenna. Bisenna.* Under these different names has been brought into notice, as a powerful tæniafuge, the bark of an Abyssinian tree, the botanical character of which has recently been determined by M. Brongniart from dried specimens brought to Paris by M. Courbon. The tree is leguminous, and belongs to the family of the Mimoseæ. M. Brongniart names it *Albizzia anthelmintica*. The bark is in flat pieces from five to ten inches long, smooth, slightly fissured, of a rusty-gray colour exteriorly, and pale-yellow and fibrous within. It consists of four layers, one of which contains very large cells, with thick coats, and is supposed to be the active part. MM. E. Caventou and Legendre have examined the bark, and found in it no alkaloid, but a peculiar, acid, resinous substance, having an acrid taste, analogous to that of the bark, of which it is probably the active principle. The Abyssinians employ the powdered bark, in the dose of about two ounces, which they take in various ways, suspended in water or other liquid, or mixed with flour in the form of bread, or made into a confection with honey, butter, &c. It is taken in the morning, three or four hours before breakfast, and no other precautions are used. It produces no pain nor any disturbance of the functions, not even purging actively. Fragments of the worm are voided the same evening, and the greater

portion of it the next day. Successful trials of the remedy have been made elsewhere than in Abyssinia, though M. Rayer has collected cases which tend to discountenance the opinion of its vermifuge powers. But the bark may in these instances have been injured by time. (See *Ann. de Thérap.*, 1862, p. 161.) W.

MESQUITE GUM. *Gum Mesquite. Gum Mezquite.* This is the product of *Algarobia glandulosa* (Torrey and Gray, *Flor. of N. Amer.*, i. 399), a small thorny tree or shrub, belonging to the family of *Mimoseæ*, and growing in New Mexico, Texas, and other neighbouring regions, where it covers vast extents of country. Captain R. B. Marcy, of the U. S. Army, who commanded an expedition sent by our government into that region, gives a particular account of the tree, in a letter to Messrs Rushton & Co., of New York. He states that it was first described by Dr. Edwin James, who attended Colonel Long's exploring expedition to the Rocky Mountains about fifty years since. The specimens collected by Dr. James were submitted to Dr. Torrey, by whom the botanical character of the plant was determined. According to Captain Marcy, the tree is found between 26° and 36° of N. latitude, and extends from 97° to 103° of longitude, over a region containing more than 500,000 square miles. In its botanical affinities and habits, it is closely analogous to the Acaciæ, which yield gum arabic. The fruit is a long, compressed pod, filled with a sweep pulp, which is said to be used as food. A gum exudes from the stem and branches, especially when wounded, which hardens in the dry season, sometimes in masses as large as a hen's egg.

Specimens of this gum were collected, and sent for examination to various persons in the Atlantic cities, by Dr. Geo. G. Shumard, of the U. S. Army, who was attached to Captain Marcy's expedition. A portion received by one of the authors was in irregular, roundish pieces, of various sizes, and of different hues, from colourless transparency to a dark amber-brown. Some of them had the fissured appearance of the best Turkey gum. Examined by Prof. Procter, the gum was found to resemble gum arabic in its solubilities, but to differ from it essentially in some of its chemical reactions. The most striking points of difference are that solution of gum mesquite is not precipitated by subacetate of lead, and a strong solution is not coagulated by borax. (*Am. Journ. of Pharm.*, xxvii. 224.) Dr. Campbell Morfit, of Baltimore, found it to approximate very closely to gum arabic in ultimate composition, its constituents being carbon, hydrogen, and oxygen, with three per cent. of inorganic matter. He found also a very little bassorin (0·206 per cent.), which did not exist in the specimens examined by Prof. Procter. (*Am. Journ. of Sci. and Arts*, March, 1855, p. 264.)

There can be little doubt that this gum has all the valuable medicinal properties of gum arabic, and might be substituted for it in all cases, with this considerable advantage, that it may be added to diluted solution of subacetate of lead, so as to communicate to that preparation demulcent properties, in addition to those of a sedative and astringent, for which it is so much used as a local application. W.

METHYLIC ALCOHOL. SPIRITUS PYROXILICUS RECTIFICATUS (*Br.* 1864). PYROLIGNEOUS SPIRIT. *Pyroxylic Alcohol. Pyroxylic Spirit. Wood Spirit. Wood Alcohol. Wood Naphtha.* Having been discarded from the Br. Pharmacopœia, at the late revision of that work, methylic alcohol has been transferred from the first part of the Dispensatory to the third. It was discovered in 1812 by P. Taylor, and was afterwards examined by Macaire and Marcet, Liebig, Dumas and Peligot, Kane, and others. When wood is subjected to destructive distillation, there is formed, besides acetic acid, tar, and other products (see *page* 19), about 1 per cent. of an inflammable, volatile liquid, which, when separated and purified, constitutes pyroxylic spirit. The crude liquor, derived from the wood, separates on standing into two liquids; the lighter containing the tarry matters, and the heavier consisting of water, acetic acid, pyroxylic spirit, &c. The heavier liquid is saturated with lime, and subjected to distillation, whereby the impure pyroxylic spirit first comes over, mixed, however, with various compounds, among which are aldehyd and pyroacetic spirit (acetone). This, after having been redistilled, and deprived of water by repeated rectifications from lime, forms the *pyroxylic spirit of commerce*. The spirit of commerce is purified by adding to it as much chloride of calcium as it can dissolve, and allowing the mixture to stand for a few days. The pyroxylic spirit unites with the chloride of calcium, and the compound formed is subjected to distillation to separate certain contaminating substances, which distil over. Finally, the pyroxylic spirit is separated from the chloride of calcium by the addition of water and a new distillation, and from water by rectification from dry lime. M. Berthelot has succeeded in producing wood-spirit synthetically by uniting the elements of water with marsh gas (C_2H_4), through the instrumentality of chlorine. (*Chem. Gaz.*, Jan. 15, 1858, p. 33.)

Properties. Pure anhydrous pyroxylic spirit is a mobile, colourless liquid, possessing a hot, pungent taste, and a peculiar aromatic smell, recalling that of acetic ether. It mixes in all proportions with water, alcohol, and ether, without having its transparency disturbed. It burns like alcohol, but with a less luminous flame. Its sp.gr. as a liquid is 0·798; as a vapour, 1·041. (*Regnault.*) Its vapour is irritating to the eyes. It boils at 140°, and during ebullition its vapour causes concussions, which render its distillation difficult, but may be prevented by placing in the bottom of the vessel a layer of mercury. As a solvent it resembles alcohol, all bodies soluble in that menstruum being likewise soluble

in pyroxylic spirit. As it has the same relation to the compound radical, *methyl* (C_2H_3), that common alcohol has to *ethyl* (C_4H_5), it is deemed an alcohol, and called *methylic alcohol*. It consists of two eqs. of carbon 12, four of hydrogen 4, and two of oxygen 16=32; and its empirical formula is $C_2H_4O_2$. Considered as a hydrated oxide of methyl, its formula is C_2H_3O+HO. Viewed as a bihydrate of methylen, it is represented by C_2H_2+2HO. According to Mr. Reuben Phillips, pyroxylic spirit usually contains sulphur, not easily separated from it.

The officinal pyroxylic spirit was directed in the Br. Pharmacopœia to have a sp. gr. from 0·841 to 0·846. From the density, thus recognised, it might be implied that not the pure, but the commercial pyroxylic spirit was contemplated, which has a straw-yellow colour, and a powerful odour of wood-smoke. But the Pharmacopœia also directed that the spirit should be without action on litmus-paper, free from smoky taste, and not rendered turbid by water. It therefore intended a purified spirit; and the greater density must be ascribed to the presence of the 10 per cent. of water allowed. According to Mr. Morson, of London, the impure commercial spirit, which is unfit for medical use, may be purified "by largely diluting it with water, when an oily substance separates, after the removal of which the spirit may be recovered by distillation." By passing the mixed liquids through animal charcoal, the purification is rendered more complete. Pyroxylic spirit has been confounded with pyroacetic spirit. They may be distinguished, according to Mr. Scanlan, by chloride of calcium, which is without action on the latter, but dissolves in the former. In applying the test, a drop or two of a *saturated* solution of chloride of calcium is added to the doubtful liquid in a test tube. This solution is immiscible with pyroacetic spirit, separating after agitation, but dissolves instantly in pyroxylic spirit. The liquid examined must be so pure as not to separate into two layers, nor to become milky with water.

It is sometimes desirable to be able to distinguish the presence of methylic alcohol in ordinary alcohol, and in ether or nitrous ether which may have been prepared from the methylated instead of the pure spirit. For this purpose, Mr. W. Young proposes a solution of permanganate of potassa as a test. Dissolve a grain of the crystallized permanganate in a fluidounce of distilled water. If ten minims of this solution be added to four fluidrachms of pure alcohol in a test tube, the bright pink colour of the former fluid will be retained at least ten minutes, after which it will gradually fade. If only ten per cent. of methylated alcohol be contained in the alcohol, the solution, instead of retaining its colour for some time, will almost instantly change to a pale-brown tint. With a larger proportion of the methylic alcohol, the change will be even more striking. One part of methylic alcohol can be thus readily detected in 300 of proper alcohol. The same test will detect methylic alcohol in ether and sweet spirit of nitre; but, in the latter case, the spirit should be purified from acid by mixing it with an equal measure of solution of potassa twice as strong as the officinal, and, after the mixture has stood an hour, distilling off the original measure of the nitrous spirit. (See *Am. Journ. of Pharm.*, Jan. 1866, p. 58; from *Pharm. Journ.*, Nov. 1865.) For a method of detecting methylic alcohol in any mixture, by Mr. John T. Miller, see *Pharm. Journ.* (2d ser., vii. 318).

Medical Properties, &c. Pyroxylic spirit, under the incorrect name of naphtha, was introduced as a therapeutic agent, some years ago, by Dr. John Hastings, of London, who proposed it as a remedy for consumption. It exerts no curative power over this disease, but may be usefully employed to palliate the cough and lessen the febrile excitement which attend it. The therapeutic properties of pyroxylic spirit have not been fully investigated; but, so far as observation has gone, it may be ranked as a narcotic, sedative, and anti-emetic. In chronic vomiting, whether dependent on functional or organic disease, Dr. Christison has found it useful, having frequently seen the vomiting arrested or greatly mitigated by its use. Dr. D. W. Yandell speaks favourably of its efficacy in diarrhœa and dysentery. It is not improbable that the impurities in the commercial spirit may have some remedial efficacy; and the purified spirit directed by the Br. Pharmacopœia may be less efficacious than the impure. The dose is from ten to forty drops, three times a day, sufficiently diluted with water. At one time it was doubtful whether the substance, used by Dr. Hastings under the name of naphtha, was pyroxylic or pyroacetic spirit; but it is now decided to have been the former.

Crude pyroxylic spirit, varying in density from 0·846 to 0·890, is employed by hatters and varnish-makers for dissolving resinous substances, and by chemists for burning in lamps as a substitute for alcohol. For the latter purpose it is more economical than alcohol; giving out more heat for equal weights.

In Great Britain alcohol is subjected to a heavy duty, which, until lately, prevented it from being used in many manufactures; because the products of its use can be more cheaply obtained from abroad. The British parliament, wishing to encourage the use of alcohol in the arts, but not as a beverage, passed an act in 1855, allowing it to be used duty-free, provided it be mixed with at least one-ninth of its bulk of pyroxylic spirit, which renders it unfit for drinking, but does not spoil it for use in the arts. This mixture is called *methylated spirit*, and is now employed extensively in Great Britain, by hatters, brass founders, and cabinet-makers for dissolving shell-lac and other resinous substances, and by manufacturing chemists for making ether, chloroform, and sweet spirit of nitre.

From the purification of pyroxylic spirit already referred to, so as to deprive it of offensive taste, it has been supposed that the intended operation of the British revenue laws might be evaded; but, in opposition to this idea, it is asserted that the purifying process is too expensive, on the large scale, to render it available for the purpose. The use of this spirit, however purified, would be unjustifiable in medical preparations, unless officinally recognised. B.

MILK, CONCENTRATED. *Preserved Milk.* As in the case of fresh meat, it is an important object to obtain milk in a concentrated form, capable of being preserved for an indefinite time, and so that, on any occasion when it may be wanted for use, it may be restored to the ordinary condition of milk by simply diluting it with water. Various processes have been employed for the purpose; but the following, by M. Martin de Lignac, is probably as little liable to objection as any one hitherto made public. Milk immediately from the cow is put into shallow boilers with a flat bottom, to the depth of about two inches, and heated by means of a water-bath. For every pint of milk an ounce of white sugar is added; and, so long as the heat is continued, the contents of the boilers are constantly stirred, so as to favour evaporation. When the volume is reduced four-fifths, the concentrated liquid is poured into cylindrical cans, the opening of which is hermetically closed by tin solder. These cans are arranged in a boiler, constructed, like steam boilers, so as to support a pressure within; and vapour is introduced at the temperature of 218° or 219° F. As soon as the boxes have been thus exposed to heat, the preparation is completed. When the can is opened for use, it will be found filled with a pasty substance, somewhat translucent, and of a yellowish-white colour. Diluted with five times its weight of water, this substance offers all the exterior and nutritive characters of ordinary milk. After the opening of the can, the milk will keep readily for ten days or more, especially if a little of it is taken out every day, so as to change the surface in contact with the air. The sugar employed in the process contributes greatly to the preservation of the milk. The high temperature to which it is exposed for a time contributes also greatly to the same end by destroying the ferments which the milk may contain. An objection to the preparation is the taste of boiled milk which it acquires in the process. M. Payen recommends, in order to obviate this defect, that the evaporation should be effected *in vacuo* by means of vapour, aided by agitation with mechanical stirrers. (*Journ. de Pharm.*, Mars, 1868, p. 195.)

Under the name of "*preserved milk*," Mr. Borden, already referred to as the inventor of meat biscuit and a special extract of beef, has for some years prepared and sold in this country a concentrated form of milk; but we have seen no account of his method of proceeding. Not improbably it is the same preparation noticed in Buchner's *Neues Repertorium für Pharmacie* (A. D. 1868, xvii. 49). This is named "preserved milk," and comes into Germany through Switzerland; being prepared by an American Company at Cham, on the Lake of Zug, by evaporating, by means of a vacuum apparatus, fresh cows' milk to which sugar has been added, to the consistence of honey. Examined by Liebig, it was found to contain in one measure about four and a half measures of milk. The solid ingredients amounted to 77·56 per cent., so that almost one-half of these ingredients must consist of sugar. Excluded from the air, the preparation may be kept indefinitely without change; and, properly diluted with water, has the taste of the best milk sweetened. W.

MITCHELLA REPENS. (*Gray's Manual*, p. 172.) *Partridge-berry. Checker-berry. Winter Clover.* This must not be confounded, in consequence of its common name, with Gaultheria procumbens. It is a small evergreen, trailing, indigenous plant, creeping about the roots of trees, with fragrant flowers, and a berry-like, edible fruit, of a scarlet colour, which lasts through the winter. The whole plant is supposed to possess remedial properties, and is said to be employed, in decoction, by the Indian squaws to facilitate parturition. It appears to be diuretic, tonic, and astringent, resembling in these respects the pipsissewa, and may be used for the same purposes, and in the same manner as that plant. W.

MOMORDICA BALSAMINA. *Balsam Apple. Balsamina.* An annual climbing plant, a native of the East Indies, but cultivated in our gardens for the sake of the fruit. This is ovate, attenuated towards each extremity, angular, warty, not unlike a cucumber in appearance, of a lively red or orange-yellow colour, easily falling when touched, and spontaneously separating into several pieces. It was formerly highly esteemed as a vulnerary, and is still in use among the common people. A liniment formed by infusing the fruit, deprived of its seeds, in olive or almond oil, is applied to chapped hands, burns, old sores, piles, prolapsus ani, &c.; and the fruit itself is sometimes mashed, and used in the form of poultice. According to M. Descourtlitz, it is poisonous when taken internally, having proved fatal to a dog in the quantity of two or three drachms. An extract prepared from it is said to be useful in dropsy, in the dose of from six to fifteen grains. W.

MONESIA. Under this name, a vegetable extract from South America was, a few years since, introduced to the notice of the medical profession in France by M. Bernard Derosne, and for a time attracted much attention. Its origin was for some time uncertain; but at present it is believed to be derived from the bark of *Chrysophyllum glycyphlæum*, a tree of middling size, growing in the forests near Rio Janeiro, and else-

where in Brazil. (*Journ. de Pharm.*, 3e sér., vi. 63.) Specimens of the bark were obtained along with the extract.

The bark is in pieces, some of which are three or four lines thick, is very compact and heavy, of a deep-brown or chocolate colour, contrasting strongly with the grayish colour of the epidermis when this remains, and of smooth fracture. The extract was received from S. America in cakes weighing rather more than a pound, from three-quarters of an inch to an inch in thickness, of a dark-brown almost black colour, very brittle, of a fracture neither very dull nor very shining, and of a taste at first sweet, then astringent, and ultimately acrid; the acrimony being very persistent, and especially felt in the fauces. It is entirely soluble in water. The bark was analyzed by MM. Derosne, Henry, and Payen, and found to contain, in 100 parts, 1·2 of stearin, chlorophyll, and wax, 1·4 of glycyrrhizin, 4·7 of an acrid principle analogous to saponin, called monesin, 7·5 of tannic acid, 9·2 of a red colouring substance, 1·3 of malic acid and malate of lime, 3·0 of various salts, including silica and oxides of iron and manganese, and 71·7 of pectic acid or pectin and of lignin, including loss, besides traces of an aromatic principle and of gum. *Monesin* was obtained by treating the bark or extract with alcohol, adding to the tincture an excess of hydrate of lime in fine powder, filtering, evaporating the clear liquor to dryness, treating the residue with water and animal charcoal, filtering, and again evaporating to dryness. Thus procured it was in transparent yellowish scales, which were easily pulverized, forming a white powder. It was uncrystallizable, readily soluble in alcohol and water, to the latter of which it gave the property of frothing, and insoluble in ether. It had no power to saturate acids, was without odour, but had a slightly bitterish taste, followed by a decided and permanent acrimony in the posterior mouth and fauces. (*Journ. de Pharm.*, Janvier, 1841.) Monesia owes its activity probably to this principle and to tannic acid.

The effects of this medicine upon the system appear to be those of a moderate stomachic excitant, a general alterative, and a feeble astringent. In overdoses it is said to produce heat in the epigastrium, with obstinate constipation and tenesmus. It has been used internally with asserted advantage in diarrhœa, hæmoptysis, menorrhagia, scrofula, scurvy, the chronic catarrh of old people, and dyspepsia. As a local remedy it has been found useful in leucorrhœa, ulcerations of the mouth and fauces, spongy and scorbutic gums, carious teeth, and obstinate scrofulous and otherwise unhealthy ulcers upon the surface. The extract may be given in pill or powder, in aqueous solution, in tincture or in syrup. The dose of it is from two to ten grains, repeated every hour, two, or three hours, or less frequently. From ten grains to a drachm may be given daily. In scrofulous affections, it must be used in large quantities, and persevered in for several weeks, in order to obtain its curative effects. Monesia is applied to ulcers either by being sprinkled in powder upon the surface, or in the form of ointment made with one part of the extract and seven parts of simple ointment. Monesin, or the acrid principle, has been given internally in the dose of about half a grain, and has also been applied to ulcers.

Mr. Dupuy, of New York, states that specimens of an extract sold as monesia, which have come under his notice, bear so close a resemblance to extract of logwood as to suggest the inquiry, whether they might not really have been the product of the same plant. (*N. Y. Journ. of Pharm.*, i. 167.) W.

MOXA. The term *moxa* is employed to designate small masses of combustible matter, intended, by being burnt in contact with the skin, to produce an eschar. They are of various forms, and made of different materials. The Chinese moxa is in small cones from eight to twelve lines in height, and is prepared from the leaves of one or more species of Artemisia. *A. Chinensis* and *A. Indica* were indicated by the Dublin College; but Lindley states that it is the *A. Moxa* of De Candolle which is employed. According to some authors, the part used is the down which covers the leaves and stems; but others, with greater probability, assert that it is a fine lanuginous substance, prepared from the leaves by beating them in a mortar. A coarser and a finer product are obtained, the former of which is used for tinder, the latter worked up into moxa. A similar moxa has been made in France, by a similar process, from the leaves of *A. vulgaris*.

Various substitutes have been proposed for the Chinese moxa, all composed of some light, porous, soft, inflammable substance, which burns slowly, and thus allows the heat to be regulated according to the effect desired. Linen rolled into a cylinder, cotton formed into the same shape and enclosed in a piece of linen, cords of cotton in small masses of various shapes, and even common spunk made from the agaric of the oak, have been employed by different persons with the desired effect. But all these bodies are subject to the incovenience of requiring to be constantly blown upon, in order that their combustion may be sustained. To remedy this defect, cotton impregnated with nitre has been recommended; and the moxa usually employed is prepared from that substance. It is important that the impregnation should be uniform; as otherwise different parts of the cylinder, burning with different degrees of rapidity, would produce unequal effects upon the skin. The following process is recommended. One pound of cotton is introduced into a vessel containing two ounces of nitre dissolved in half a gallon of water, and a moderate heat applied till all the liquid is evaporated. The cotton, when perfectly dry, is formed into thin, narrow sheets, which are rolled round a central cord of linen, so as to

form a cylinder from half an inch to an inch in diameter, and several inches long. This is enclosed in a covering of silk or linen sewed firmly around it; and, when used, may be cut by a razor into transverse slices a few lines in thickness. By leaving a hole in the centre of the cylinder, the combustion will be rendered more vigorous, and a deeper eschar produced.

The pith of *Helianthus annuus*, or the common *sunflower*, has been proposed by M. Percy for the preparation of moxa, for which it is well adapted by the nitre which it contains, and which enables it to burn without insufflation. The stem, when perfectly mature, is cut into transverse sections about half an inch in thickness, which must be carefully dried, and kept in a perfectly dry place. They have this advantage, that, in consequence of the retention of the cortical portion, they may be held with impunity, while burning, between the fingers of the operator. They are, however, often defective from an insufficiency of nitre in the pith, or the unequal inflammability of different parts. It may not be improper to state, in this connection, that the sunflower has the reputation, originating in this country, of protecting against the influence of marsh miasmata. In Belgium, it is related that a locality on the Scheldt, which had been infested with fevers, had become entirely healthy, apparently through the agency of sunflowers largely planted in the vicinity. The seeds of the plant yield a useful fixed oil; and the stems serve for fuel when wood is scarce. (*N. Y. Med. Record*, Oct. 1, 1868, p. 353.)

M. Robinet has perfected the preparation of moxa, by combining the advantages of the two kinds last described. He rolls cotton round a small central cylinder of pith, and envelops the whole in a piece of muslin, which is more or less firmly applied, according to the degree of compactness required. The cylinders, thus made, burn without assistance, uniformly, and with a rapidity proportionate to their firmness.

Dr. Jacobson, of Copenhagen, has proposed, as a substitute for the ordinary forms of moxa, small cylinders formed out of strips of paper imbued with a solution of chromate of potassa; and cotton impregnated with the solution of chlorate of potassa instead of nitre, is said to answer an excellent purpose. (*Journ. de Pharm.*, xix. 608.) Small cylinders made out of strips of coarse muslin saturated with the same solution are also employed. M. Guepratt proposes paper or cotton dipped into the solution of subacetate of lead, and afterwards dried. (*Med. Exam.*, N. S., iii. 455.)

Lime in the act of slaking has been employed by Dr. Osborne. A portion of powdered quicklime, half an inch in thickness, and of suitable lateral dimensions, is applied to the skin, and confined by some convenient arrangement. A few drops of water are then added, and a degree of heat is soon evolved sufficient for a caustic effect, if the lime is allowed to remain as long as the heat continues. This may be increased or diminished by increasing or diminishing the quantity of lime employed. The eschar formed is somewhat more than double the extent of the base of the moxa. (*Dublin Journ.*, Jan. 1842.)

Medical Uses. Cauterization by fire, in the treatment of disease, has been commonly practised among savage and half civilized nations from the earliest periods of history, and has not been unknown as a remedy in the most polished communities. The ancient Egyptians and Greeks were acquainted with the use of moxa; and in China, Japan, and other countries of Asia, it appears to have been employed from time immemorial. From these countries the early Portuguese navigators introduced it into Europe; and the term *moxa* is said to have been derived from their language, though supposed by some to be of Chinese origin. The true Chinese name is said to be *kiew*. (*Percy and Laurent.*) Some years since, the remedy became very popular in France, and attracted some attention in this country. It acts on the principle of revulsion; relieving deep-seated inflammation, and local irritation whether vascular or nervous, by inviting the current of excitement to the skin. In some cases it may also operate advantageously by the propagation of a stimulant impression to neighbouring parts.

The celebrated Larrey was among those who contributed most to bring this remedy into repute. The diseases in which it was recommended by that author were amaurosis, loss of taste, deafness, paralytic affections of the muscular system, asthma, chronic catarrh and pleurisy, phthisis, chronic engorgement of the liver and spleen, rachitis, diseased spine, coxalgia, and other forms of scrofulous and rheumatic inflammation of the joints. It has also been used advantageously in neuralgia, and is applicable to chronic complaints generally in which powerful external revulsion is indicated.

The parts of the body upon which, according to Larrey, it should not be applied, are the cranium where protected only by the skin and pericranium; the eyelids, nose, and ears; the skin over the larynx, trachea, and mammary glands; over superficial tendons, projecting points of bones, and articular prominences in which the capsular ligament might be involved; the anterior surface of the abdomen; and the genitals.

As a general rule, it should be applied as near as possible to the seat of the disease; and, in neuralgic or paralytic cases, at the origin or over the course of the nerves proceeding to the part affected. Some advise that the cylinder be attached to the skin by some adhesive liquid; but a more general practice is to retain it in the proper position by a pair of forceps or other instrument. Larrey recommends that the skin around it be covered with a piece of moistened lint, having a hole in the centre to admit the base of the cylinder. The moxa should be set on fire at the summit, and the combustion sustained if necessary

by the breath, the blow-pipe, or the bellows. The size of the cylinder should vary according to the effect desired, from half an inch to an inch or more in diameter, and from a few lines to an inch in height. Any degree of effect may be obtained, from a slight inflammation to the death of the skin, by regulating the time during which the moxa is allowed to burn. When a slough is required, it should be suffered to burn until consumed. The first sensation experienced is not disagreeable; but the operation becomes gradually more painful, and towards the close is for a short time very severe. W.

MUREXIDE. A fine purple dye-stuff, made by the reaction of nitric acid on uric acid. As resulting from the action of nitric acid on urine, it was supposed by Mr. Prout to consist of purpuric acid and ammonia, and hence was named *purpurate of ammonia;* but chemists are not agreed as to its precise composition. It is now made from guano. This is first treated with muriatic acid to remove foreign substances, and then with soda to dissolve the uric acid, which is separated by neutralizing the soda with muriatic acid. The uric acid is dissolved in nitric acid, the solution is heated, and after it cools ammonia or its carbonate is added, which develops the purple colour. Murexide is obtained in crystals, which have a square form, and are of a rich-green colour by reflected, but of a purple-red by transmitted light. They are slightly soluble in cold water, more so in boiling water, and insoluble in alcohol and ether. With potassa they form a rich purple solution. (*Brande and Taylor.*) See for an article on the subject of murexide, the *Pharmaceutical Journal* (xviii. 328). W.

MURIATIC ETHER. *Æther Muriaticus. Muriate of Ethylen. Chloride of Ethyl.* This ether was discovered by Rouelle, but first obtained in sufficient quantities to permit the examination of its properties by Basse. It may be procured by several processes, but the following is the best. Distil a mixture of equal measures of concentrated muriatic acid and alcohol, and receive the product, by means of a curved glass tube, in a tubulated bottle, half filled with water at a temperature between 70° and 80°, and connected by means of a second tube with another bottle, loosely corked, and surrounded by a mixture of common salt with snow or pounded ice. The ether, as it enters the first bottle, is mixed with alcohol and acid, which are retained by the water; while the pure ether passes forward, and is condensed in the refrigerated bottle. It must be kept in strong bottles, well secured with ground stoppers covered with leather. Before being opened, the bottle should be cooled to the freezing point.

Muriatic ether is a colourless liquid, having a strong, slightly saccharine, alliaceous taste, and a penetrating, ethereal, alliaceous smell. Its sp. gr. at the temperature of 41° is 0·774. It is extremely volatile, entering into ebullition at 54°; so that in summer it may be collected in the gaseous state, in bell-glasses over water. Its density in the state of vapour is 2·22. When kindled as issuing from a fine orifice, it burns with an emerald-green flame without smoke, diffusing a strong odour of muriatic acid; but, when set on fire in quantities, it burns with a greenish-yellow, smoky flame. Water dissolves one-fiftieth of its weight of this ether, and acquires a sweetish, ethereal taste; and alcohol unites with it in all proportions. These solutions are not precipitated by nitrate of silver, showing that the chlorine present is in a peculiar state of combination. Like hydric and nitric ether, it dissolves sulphur and phosphorus, the fat and volatile oils, and many other substances. It consists of one eq. of muriatic acid 36·5, and one of ethylen 28 = 64·5; or, in volumes, of two volumes of the acid, and one volume of the vapour of ethylen, condensed into two volumes. Its formula is C_4H_4,HCl. Viewed as the chloride of ethyl, it is represented by C_4H_5,Cl.

Muriatic ether is a diffusible stimulant; but, owing to its extreme volatility, cannot be kept in the shops. It may, however, be preserved in a cool cellar, the temperature of which does not rise above 45° or 50°, being well secured in bottles, which should be placed reversed. When used as a medicine, it is generally mixed with an equal bulk of alcohol, forming what is called *alcoholic muriatic ether.* The dose is from five to thirty drops, given in sweetened water, or other convenient vehicle. W.

MUSHROOMS. *Fungi.* This extensive family of cryptogamous plants is interesting to the physician, from the consideration, that, while some of them are very largely consumed as food, others are deleterious in their nature, and capable, when eaten, of producing poisonous effects. Their substance is made up of a cellular tissue, which is usually of that soft consistence denominated fungous, but is sometimes corky, ligneous, or even gelatinous. Many of them have an agreeable odour and taste, while others are unpleasant or offensive both to the nostrils and palate. Their juice generally exhibits an acid reaction. According to Braconnot, most of them contain, among other substances, a peculiar principle denominated *fungin*, a peculiar acid called *fungic acid* usually combined with potassa, and a saccharine matter, less sweet than most other varieties of sugar, less soluble in alcohol and water than that of the cane, and distinguished by some writers as the *sugar of mushrooms.* M. Bolby found *mannite* in two different species, with *oxalic acid* in one, an acid which he supposed to be the *fumaric* in a second, and *lichstearic acid* in a third. (*Journ. de Pharm.*, 3e sér., xxiv. 236.) M. Dessaignes has ascertained the identity of the fumaric and fungic acids. (*Ibid.*, xxvi. 133.) *Fungin* constitutes the basis of these vegetables, and is the principle upon which their nutritive properties chiefly depend. It is the fleshy substance which

remains after they have been treated with boiling water holding a little alkali in solution. It is whitish, soft, and insipid; inflammable; insoluble in water, alcohol, ether, weak sulphuric acid, and weak solutions of potassa and soda; soluble in heated muriatic acid; decomposed by nitric acid, and by concentrated alkaline solutions; and converted by destructive distillation into substances resembling those which result from the distillation of animal matters. MM. Payen and Fromberg affirm that the fungin of Braconnot is nothing but cellulose; and this assertion is confirmed by M. Gobley, who attributes the animal properties ascribed to it, to the presence of unseparated albumen. M. Gobley also found the supposed peculiar saccharine matter to be mannite. He gives, as the result of his analysis of the edible mushroom, water, albumen, cellulose, mannite, extractive matters, salts, and fatty matter consisting of olein, margarin, and a peculiar concrete fatty substance analogous to cholesterin, and called by him *agaracin*. (*Ibid.*, xxix. 91.) Mushrooms are very largely cultivated in Europe for the table. They require a rich soil; but the discovery is asserted to have been recently made, that they will flourish better, and attain a much greater size, in artificial beds of sulphate of lime, in which the spores are buried mixed with powdered nitrate of potassa to the depth of about one-third or one-half of an inch; at least this is said to be true of a variety of the *Agaricus campestris*, called by the French "*l' agaric de couche.*" (*Journ. de Pharm.*, Sept. 1861, p. 196.)

It is highly important for those who employ mushrooms as food, to be able to distinguish those which are wholesome from the poisonous. The following general rules are given by M. Richard in the *Dictionnaire des Drogues*. Those should be rejected which have a narcotic or fetid odour, or an acrid, bitter, or very acid taste; which occasion a sense of constriction in the throat when swallowed; which are very soft, liquefying, changing colour, and assuming a bluish tint upon being bruised; which exude a milky, acrid, and styptic juice; which grow in very moist places, and upon putrefying substances; in fine, all such as have a coriaceous, ligneous, or corky consistence. The last, however, are injurious in consequence rather of their indigestible than of their poisonous nature. Even mushrooms which are usually edible may prove poisonous, if collected too late, or in places which are too moist. It is said, moreover, that the poisonous species sometimes become innocent when they grow under favourable circumstances. It is affirmed, for example, that mushrooms which prove poisonous in England are eaten with impunity in Russia, a fact which Mr. W. Hamilton is disposed to ascribe less to difference in the plant, than in the mode of preparation; salt being much more largely used with them by the Russian than the English cooks. (*Pharm. Journ.*, xiv. 67.) In the autumn of 1859, out of six officers of the French army stationed at Corte, who partook of mushrooms, five died. In consequence of this event, the Army Board of Health drew up instructions for the use of the army as to the mode of distinguishing the poisonous from edible mushrooms. We have no space for them here; and must content ourselves with referring to the *Journal de Pharmacie* (Nov. 1860, p. 339), and the *Pharmaceutical Journal* (Jan. 1861, p. 387). Dr. Alfred S. Taylor, the distinguished toxicologist, makes the following observations about the poisonous fungi. As a rule, he states, these fungi may be recognised by the pileus or cap having a peculiar conical or flattened shape, and by being coloured yellow, brown, green, red, or orange-red; by the want of a pink or purple colour in the gills, and by a very disagreeable odour when the plant is bruised. They generally grow under trees, in groves or woods, and are often attached to decayed animal matter. (*Guy's Hospital Reports*, A.D. 1865.) According to Mr. W. G. Smith, who is familiar with the mushroom as an article of food, nearly all the fungi with white spores or seeds are edible; and the seeds of the innocent kinds are for the most part roundish or oval, while those of the poisonous are generally angular, and in one instance are covered with spines. (*Pharm. Journ.*, Jan. 1869, p. 433; from *Gardener's Chronicle.*) Immense quantities of mushrooms are eaten in France, Germany, Italy, and other parts of continental Europe; and they are said to constitute the chief food of the people in certain provinces.

Some experiments of M. Gerard would tend to show that poisonous mushrooms may be rendered innocent, by treating them with water slightly acidulated with vinegar, before cooking them. About a pound avoirdupois of poisonous mushrooms, cut into pieces, are to be macerated for two hours in a quart of water, acidulated with two or three spoonfuls of strong vinegar, and afterwards to be washed with a large quantity of water. Next day they are to be put into cold water, boiled for half an hour, then taken out, washed, and dried. They are now fit for food. (See *Am. Journ. of Pharm.*, xxv. 274.) But subsequent experiments by MM. Demartis and Corne, of Bordeaux, have proved that this method is not always to be relied on; as certain mushrooms, after having been treated in the manner suggested, have nevertheless produced fatal effects on animals; and, as the same mushrooms may be poisonous at one season or in one situation, and innocent in another, the inference is that those experimented on by M. Gerard, though ordinarily poisonous, may not have been so in that particular instance. (*Journ. de Pharm.*, 3e sér., xxi. 468.)

In a communication on the poisonous principle of mushrooms, made by M. Letellier, to the Paris *Academy of Medicine*, the author gave the following summary of the conclusions to which his investigations had conducted him. The poisonous mushrooms of the genus Agaric, section Ammonites, owe their fatal effects to the same narcotic principle,

which is a fixed alkaloid, uncrystallizable, and capable of being precipitated by nothing but iodine or tannin, to which he thinks the name of *amanitine* (*amanitia*) should be applied. The different species confounded under the name of *bulbous agaric*, possess, besides this, a deleterious acrid principle. The best treatment of poisoning by these species consists in the use of oleaginous emeto-cathartics, attended and followed by tannin in very strong aqueous decoction. (*Arch. Gén.*, Avril, 1866, p. 493.) MM. Sicard and Schoras make a similar statement as to the alkalinity of the poisonous principle, as they found it capable of forming salts with the acids. A salt prepared by them was extremely poisonous. A portion almost infinitely small always proved fatal to frogs; and the effects were the same as those produced by curarin. (*Journ. de Pharm.*, 4e sér., i. 442, A. D. 1865.)

The symptoms produced by the poisonous mushrooms are anxiety, vertigo, nausea, faintness, vomiting, and, if they are not rejected from the stomach, somnolence, stupor, small and intermittent pulse, tension of the abdomen, cold extremities, livid skin, and death in thirty-six or forty-eight hours. Sometimes violent pains in the stomach and bowels are experienced; and occasionally severe vomiting and purging occur, and save the patient. Blackish or bloody dejections, with tenesmus, sometimes attend the action of the poison. In some instances the symptoms are said to be remarkably like those from alcoholic drinks. The symptoms are not generally experienced until several hours, usually from five to ten, after the mushrooms have been eaten, showing that their deleterious effects depend upon the entrance of the poisonous principle into the circulation. The remedies are emetics, if the physician is called in time, accompanied with the free use of warm drinks, and followed by cathartics. After the evacuation of the alimentary canal, demulcent and nutritive beverages should be given, and the strength of the patient sustained by mild tonics or stimulants. Ether is particularly recommended; and opiates would no doubt prove serviceable in the absence of coma, should any irritability of the stomach and bowels remain.

Some of the poisonous species have been used as medicines; but in this country they are never employed; and too little seems to be precisely known of their modes of action, and their qualities, even in the same species, vary too much, according to the circumstances of their growth and situation, to justify their introduction into the materia medica, without further investigation. A species of *Lycoperdon* or puff-ball, *L. proteus*, was thought to have been proved by Dr. B. W. Richardson, of London, to have remarkable narcotic and anæsthetic properties. Having noticed that the smoke of this fungus was used in the country for stupefying bees, he experimented with the fumes upon various animals, which, when caused to inhale them, became insensible, and could be operated on without evincing any signs of pain. When carried far, they caused death. He had himself inhaled the fumes clarified by passing them through water, and experienced symptoms of intoxication and drowsiness. They were procured by burning the fungus. (*Lond. Med. Times and Gaz.* June, 1853, p. 610.) Mr. Thornton Herapath, however, maintains, as the result of his experiments, that these anæsthetic effects are in reality not owing to any narcotic principle present in the fungus, but to the carbonic oxide gas generated during their combustion. (*Philosoph. Magaz.*, July, 1855.) A tincture of *Lycoperdon bovista*, made in the proportion of four troyounces to a pint of alcoholic menstruum, has been used by Dr. Addinell Hewson, of Philadelphia, in nervous diseases, in the dose of a teaspoonful. (*Am. Journ. of Pharm.*, March, 1867, p. 113.) W.

MUSK, ARTIFICIAL. *Moschus Factitius.* This is prepared, according to M. Elsner by adding, by small portions at a time, one part of rectified oil of amber to three parts of fuming nitric acid. The resulting resin is washed with water, to separate acid, and brought to the consistence of a firm extract in a water-bath. Thus prepared it is a dark brownish-red substance, having a burning, bitter, aromatic taste, and a musky odour. It is very soluble in alcohol, ether, and the volatile oils; and its alcoholic solution reddens litmus. Triturated with caustic potassa, it gives off ammonia. When set on fire, it burns with a very smoky flame, and leaves a shining porous charcoal. Its formula, deduced from its combination with protoxide of lead, is $C_{15}H_8N_2O_7$. Comparing its composition with that of the oil of amber, the action of the nitric acid evidently consists in eliminating a portion of carbon and hydrogen, adding to the oxygen, and furnishing nitrogen. M. Elsner found oil of amber to consist of several oily principles, having different boiling points, one of which, resembling eupion, he calls *amber eupion*. As this substance yields artificial musk by the action of fuming nitric acid, he believes the property possessed by oil of amber yielding the same substance to be due to its presence. (*Journ. de Pharm.*, 3e sér., ii. 144.) During the reaction of nitric acid with oil of amber, Dr. John T. Plummer, of Indiana, has observed that oxalic acid is generated.

Dr. S. W. Williams gives the following formula for the preparation of artificial musk. Add gradually, drop by drop, *three drachms and a half* of concentrated nitric acid to *a drachm* of rectified oil of amber, contained in a glass tumbler or very large wineglass. The mixture grows hot, and emits offensive fumes, which the operator must avoid. When the ordinary nitric acid is employed, which is not of full strength, the reaction must be assisted by heat; in which case Dr. Williams recommends that the vessel containing the mixed ingredients be placed in a plate before the fire, they being, meanwhile, continually stirred with a glass rod. After the mixture has remained at rest for 24 hours, it acquires

a resinous appearance, and divides into two portions, an acid liquid below, and a yellow resin above, resembling musk in smell. This being thoroughly washed, first with cold and then with hot water, until all traces of acid are removed, is the artificial musk. (See *Am. Journ. of Pharm.*, viii. 14.)

Artificial musk is an antispasmodic and nervine, and possesses the general therapeutic properties of the natural substance, though in a weaker degree. It is praised by Dr. Williams in the treatment of hooping-cough, typhoid states of fever, and nervous diseases generally. When combined with water of ammonia, compound spirit of lavender, or laudanum, he found no remedy so efficient in the sinking faintness occurring in the last stage of pulmonary consumption. The average dose for an adult is ten grains; for a child two years old, from half a grain to a grain, repeated, in each case, every two or three hours. It may be prepared as the musk mixture, or with almonds in the form of emulsion. According to Berzelius, *tincture of artificial musk* is formed by dissolving *a drachm* of the musk in *an ounce* of alcohol, equivalent to *ten fluidrachms*, of the sp. gr. 0·835. Of this the dose for an adult is a teaspoonful. This tincture has been employed by Prof. Hauner, chief physician of the Children's Hospital at Munich, in uncomplicated spasm of the glottis, with invariable success in more than thirty cases. Though artificial musk is not equal in power to the natural substance, when genuine, yet it is in all probability superior to the adulterated article, so frequently sold under the name of musk. B.

MYRICA CERIFERA. *Wax-myrtle. Bay-berry.* This is an indigenous shrub, growing in great abundance in the sandy soil along the sea-shore, and even on the shores of our northern lakes. It belongs to Diœcia Tetrandria in the Linnæan system, and the natural order Myricaceæ. The genus is characterized by its sterile flowers in cylindrical, and its fertile in ovoidal closely imbricated catkins, without calyx or corolla, solitary under a scale-like bract with a pair of bractlets; the stamens 2 to 8, with filaments somewhat united below; the ovary with 3 scales at its base, and 2 thread-like stigmas; the fruit a small spherical nut. (*Gray's Manual.*) The leaves of the wax-myrtle are oblong-lanceolate, narrower at their base, entire or somewhat toothed near the apex, shining, with resinous dots on both sides, and very fragrant when rubbed. The fruit is covered with a coating of white wax, and sometimes continues on the plant for two years or more. The shrub is from three or four to ten feet high, often thickly crowded, and, under such circumstances, scenting the air with its spicy odour. The coating of wax upon the surface is collected, and known in commerce as *myrtle wax*. (See *Vegetable Wax*, page 249.) A volatile oil might probably be collected by distillation from the leaves, and used for purposes similar to those to which oil of pimento is applied. The bark of the stem and root is supposed to possess valuable remedial properties, and has been employed to a considerable extent. In the dried state it is in quilled pieces of variable length, covered with a thin epidermis of a grayish colour somewhat mottled, and marked with slight circular fissures. Within the epidermis the colour is reddish-brown. The bark is brittle, and of a peculiar, astringent, bitterish and pungent taste, followed by a slight sense of acrimony. Its powder has a peculiar aromatic odour, and irritates the nostrils and throat when inhaled. It yields its virtues to water and alcohol. Chemically examined by Mr. Geo. M. Hambright, it was found to contain volatile oil, starch, lignin, gum, albumen, extractive, a red colouring substance, tannic and gallic acids, an acrid resin soluble in alcohol and ether, an astringent resin soluble in alcohol and not in ether, and a peculiar acrid principle having acid properties, analogous to saponin, for which the name of *myricinic acid* is proposed. (*Am. Journ. of Pharm.*, May, 1863, p. 193.)

In relation to its effects on the system, the bark appears to be moderately tonic and astringent, with probably expectorant properties connected with its acrid principle, and in large doses emetic. It has been considerably used by the "eclectics," in diarrhœa, jaundice, scrofula, &c. Externally the powdered bark is used as a stimulant to indolent ulcers; and the decoction as a gargle and injection in chronic inflammation of the throat, leucorrhœa, &c. The dose of the powder is twenty or thirty grains, of a decoction made with an ounce to the pint of water, one or two fluidounces. An alcoholic extract, very inappropriately named *myricin*, is given in the medium dose of about five grains. W.

MYROBALANS. *Myrobalani.* These are the fruits of various East India trees, particularly of different species of Terminalia. They are noticed here partly on account of their ancient reputation, partly because they are still occasionally to be found in the shops, though seldom if ever used in medicine. Five varieties are distinguished by authors. 1. *Myrobalani bellericæ.* These are obtained from *Terminalia Bellirica.* They are roundish or ovate, from the size of a hazelnut to that of a walnut, of a grayish-brown colour, smooth, marked with five longitudinal ribs, and sometimes furnished with a short, thick footstalk. They consist of an exterior, firm, resinous, brown, fleshy portion, and an interior kernel, which is light-brown, inodorous, and of a bitterish very astringent taste. 2. *Myrobalani chebulæ.* This variety is produced by *Terminalia Chebula.* The fruit is oblong, pointed at each extremity, from fifteen to eighteen lines in length, of a dark-brown colour, smooth and shining, with five longitudinal wrinkles but without footstalks. In their internal arrangement and their taste, they resemble the preceding. 3. *Myrobalani citrinæ* vel *flavæ.* These are from a variety of the same tree which affords the last-mentioned

myrobalans, from which they differ only in being somewhat smaller, of a light-brown or yellowish colour, and of a taste rather more bitter. They were formerly sometimes sold in the shops of Philadelphia, under the name of *white galls*, to which, however, they bear no other resemblance than in taste. 4. *Myrobalani Indicæ* vel *nigræ*. These are thought to be the unripe fruit of *Terminalia Chebula*, or *T. Bellirica*. They are ovate-oblong, from four to eight lines long, and from two to three lines thick, of a blackish colour, wrinkled longitudinally, and presenting, when broken, a thick brown mass, without kernel, but with a small cavity in the centre. They are sourish and very astringent. 5. *Myrobalani emblicæ*. This variety is wholly different from the preceding, and derived from a plant having no affinity to the Terminaliæ, namely, the *Phyllanthus Emblica* of Linnæus. It is often in segments, as kept in the shops. When the fruit is entire, it is blackish, spherical, depressed, of the size of a cherry, presenting six obtuse ribs with as many deep furrows, and separating into six valves, and has a strongly astringent and acidulous taste.

These fruits were in high repute with the Arabians, and were long employed by European practitioners, as primarily laxative and secondarily astringent, in various complaints, particularly diarrhœa and dysentery. Their dose was from two drachms to an ounce. They are not now employed as medicines. We have been told that they have been used as a substitute for galls in the preparation of ink-powder. W.

NAPHTHALIN. This may be obtained by subjecting coal tar to distillation, when it passes over after the coal naphtha. For a method of preparing it pure, and on a large scale for commercial purposes, see a paper by Vohl, in the *Journ. de Pharm.* (Mai, 1868, p. 399; from *Polyt. Journ.*). It is a white, shining, crystalline substance, fusible at 176° and boiling at 423°. According to Kopp, its sp. gr. in the liquid state is 0·9774, according to Alluard, at 210° F., 0·9628. (*Journ. de Pharm.*, Avril, 1860, p. 318.) It is soluble in alcohol, ether, naphtha, and the oils, but insoluble in water. Notice has already been taken of the artificial preparation of alizarin, a colouring principle of madder, from naphthalin, by M. Roussin. (See *Rubia*, p. 745.) It has been proposed by Dupasquier as an expectorant, and has been found, on trial, to act decidedly as such. In the impending suffocation, sometimes occurring in the chronic pulmonary catarrh of old persons, and in humoral asthma, it facilitated expectoration in a remarkable degree. Being a stimulating remedy, it is not proper in acute bronchitis, or where pulmonary inflammation exists. The dose is from eight to thirty grains, given in emulsion or syrup, and repeated at intervals of a quarter of an hour, until an abundant expectoration takes place. (*Journ. de Pharm.*, 3e sér., ii. 513.) M. Rossignon considers naphthalin to act like camphor, and to be capable of replacing it on many occasions as a remedy. It produces excellent effects in verminose affections. It has been found useful by M. Emery, in the form of ointment, made by mixing a scruple of naphthalin with five drachms of lard, in dry tetter, psoriasis, and lepra vulgaris. (*Annuaire de Thérap.*, 1843, pp. 64 and 66.) B.

NAPLES YELLOW. A yellow pigment prepared by calcining a mixture of lead, sulphuret of antimony, dried alum, and muriate of ammonia, or a mixture of carbonate of lead, diaphoretic antimony, dried alum, and muriate of ammonia. (*Gray.*) W.

NARCISSUS PSEUDO-NARCISSUS. *Daffodil.* This well-known bulbous plant is a native of Europe, but very common in the gardens of this country, where it attracts attention by the early appearance of its conspicuous yellow flowers. Both the bulb and flowers have been used in medicine. The latter have a feeble peculiar odour, and both have a bitter mucilaginous taste. They are emetic, though uncertain in their operation. It is probable that the flowers of the wild plant are more powerful than those of the cultivated. They may be given dried and powdered, or in the form of extract. The dose of the powder, to produce an emetic effect, varies, according to the statements of different physicians, from a scruple to two drachms; while the extract is said to vomit in the dose of two or three grains. It is conjectured that the emetic property is developed by the agency of water. The bulb is most powerful in the recent state, and, within our own knowledge, is occasionally used as an emetic in domestic practice in the country. When dried and powdered, it has been given in the dose of thirty-six grains without vomiting. The author, when a student of medicine, wishing to ascertain whether this root might not, like ipecacuanha, possess diaphoretic properties, took a dose of it suspended in some warm water at bedtime, and on awaking in the morning found himself bathed in a copious sweat, and freed, at the same time, from the symptoms of a severe attack of catarrh under which he was at the time labouring. The flowers are said also to possess antispasmodic powers, and have been used in France, with supposed advantage, in hooping-cough, epilepsy, and other convulsive affections. It is probable, however, that they operated in these cases by their nauseating or emetic property. They have, moreover, been advantageously employed in diarrhœa, dysentery, and intermittent fever. Other species of Narcissus are said to possess the same properties, though they have not been so much used. W.

NARD. *Spikenard.* Several aromatic roots were known to the ancients under the name of *nardus*, distinguished, according to their origin or place of growth, by the names of *nardus Indica*, *nardus Celtica*, *nardus montana*, &c. They are supposed to have been de-

rived from different species of *Valeriana*. Thus the nardus Indica is referred to *V. Jatamensi* of Bengal, the nardus Celtica to *V. Celtica*, inhabiting the Alps, Apennines, &c., and the nardus montana to *V. tuberosa*, which grows in the mountains of the South of Europe. The Indian nard, or spikenard, sometimes also called Syrian nard, is still occasionally to be found in the shops. It is a small delicate root, from one to three inches long, beset with a tuft of soft, light-brown, slender fibres, of an agreeable odour, and a bitter, aromatic taste. It was formerly very highly esteemed as a medicine, but is now almost out of use. Its properties are analogous to those of the officinal valerian. W.

NASTURTIUM OFFICINALE. R. Brown. *Sisymbrium Nasturtium.* Linn. *Water-cress.* A small, perennial, herbaceous, succulent plant, growing in springs, rivulets, and ponds, in North America, Europe, and some parts of Asia. The fresh herb has a quick penetrating odour, especially when rubbed, and a bitterish, pungent taste, but loses both when dried. In sensible and medical properties it bears some resemblance to scurvy grass, though milder, and on this account is preferred for the table. It is thought to be useful in scorbutic affections, and visceral obstructions. The expressed juice is sometimes given in the dose of one or two ounces; but the herb is more frequently used in the form of a salad. Other species of Nasturtium, as *N. Palustre* or *marsh water-cress*, and *N. amphibium* or *water-radish*, grow in similar situations with the *N. officinale*, and possess similar virtues. W.

NERIUM OLEANDER. A notice of the *oleander*, so well known as an ornamental shrub of our conservatories, is introduced here mainly on account of its presumed poisonous properties. The peasantry in the South of France, where the plant grows wild, employ the powdered bark as a poison for rats, and death is said to have occurred from eating food roasted by the oleander wood. (*Mérat et De Lens.*) The leaves, boiled in lard or oil, yield an ointment which is said to be very efficacious, rubbed on the skin, against insects that infest the person. A case has been recorded in which a man, in Hindostan, swallowed somewhat more than an ounce of the juice of *Nerium odorum*, with the effect of producing the most violent narcotic symptoms, as stupor, stertorous breathing, and convulsions, followed by great prostration, with involuntary evacuations, from which, however, after two days of danger, he recovered under the use of emetics, followed by supporting treatment. (*B. and F. Med.-chir. Rev.*, Am. ed., April, 1860, p. 387.) M. Latour has made a careful chemical examination of oleander, from which he obtained the following results. 1. The poisonous principle exists in the leaves, bark, and flowers, but most largely in the bark. 2. This principle is of a resinous nature, and not volatile, and is found more largely in the wild than the cultivated plant. 3. The solubility of this resin in water is much facilitated by alkaline salts, and hence it exists in the watery extract. 4. The distilled water of the bark and leaves possesses some activity, which it owes to a small portion of the resin carried over with the steam. (See *Am. Journ. of Pharm.*, March, 1858, p. 172.) Prof. E. Pelikan, of St. Petersburg, has made experiments with this plant on frogs, from which he concludes that the poisonous properties reside in the yellow resin of M. Latour; and that the poison acts especially on the heart, the pulsations of which it first accelerates, then retards, and finally causes to cease altogether. He thinks that the alcoholico-aqueous extract closely resembles digitalis, and might be substituted for it in therapeutics. (*Journ. de Pharm.*, 4e sér., iii. 206.) According to Gmelin (xvii. 596), two alkaloids have been discovered in oleander; one by Lucas, named *pseudocurarin;* the other by Leukwasky, named *oleandrin*. Both neutralize acids; the former dissolves in water and alcohol, but not in ether, and is neither volatile nor poisonous; the latter is yellow, amorphous, very bitter, very slightly soluble in water, but more freely in alcohol and ether, and poisonous in its action on the system. W.

NIGELLA SATIVA. *Nutmeg-flower. Small Fennel-flower.* A small annual plant, growing wild in Syria and the South of Europe, and cultivated in various parts of the world. The seeds, which are sometimes kept in the shops under the name of *semen nigellæ*, are ovate, somewhat compressed, about a line long and half as broad, usually three-cornered, with two sides flat and one convex, black or brown externally, white and oleaginous within, of a strong, agreeable, aromatic odour, like that of nutmegs, and a spicy, pungent taste. Their chief constituents are a volatile and fixed oil, and a peculiar bitter principle denominated *nigellin*, which exists in the seeds in very minute proportion. (*Journ. de Pharm.*, 3e sér., ii. 128.) In India they are considered as stimulant, diaphoretic, and emmenagogue, and are believed to increase the secretion of milk. They are also used as a condiment, and as a corrigent or adjuvant of purgative and tonic medicines. W.

NITRATE OF COPPER. *Cupri Nitras.* This well-known salt has been employed with advantage, as a caustic, in a severe case of ulceration of the throat and tongue, and in several similar cases, by Dr. William Moore, of Ballymoney, Ireland. The application is attended with no danger, provided the ulcer or part is dried before applying the caustic, and afterwards smeared with oil. (See *Braithwaite's Retrospect*, xxv. 201.) B.

NITRATE OF SODA. *Cubic Nitre.* This salt may be formed by treating carbonate of soda with nitric acid. It is found naturally in the desert of Atacama and elsewhere in Peru, where it forms beds of vast extent. Attempts were made between 1820 and

1830 to export it to England and the United States; but the cargoes were unsalable. Soon afterwards, however, its value became known; so that at present large quantities are exported from Peru, being consumed in the manufacture of sulphuric and nitric acids, and as a fertilizer. The salt has also been found largely in Brazil, in the Province of Bahia, near the river San Francisco. (*Am. Journ. of Pharm.*, Nov. 1861, p. 502.) For a particular account of the nitrate of soda deposits of Peru, in a commercial point of view, see *Ibid.* (March, 1862, p. 263).

The crude salt, as it comes from Peru, is in saline lumps, rather soft and friable, and damp on the surface. It is distinguished into varieties according to its colour and state of aggregation, as *white compact*, *yellow*, *gray compact*, *gray crystalline*, and *white crystalline*, and varies very much in purity, containing from 85 to only 20 per cent. of the pure salt. Some of the varieties contain iodine. The impurities consist of common salt, sulphate and carbonate of soda, and chloride of calcium. Occasionally borate of lime, associated with borate of soda, is found under the beds of the nitrate.

Nitrate of soda, when pure, is a white salt, crystallizing in rhomboidal prisms, and having a sharp, cooling, and bitter taste. It attracts moisture slightly from the air, and dissolves in about twice its weight of water, at 60°. It has been praised as a remedy in dysentery by two German physicians, Drs. Velsen and Meyer, given in the quantity of from half an ounce to an ounce in the course of the day, dissolved in gum water, or other mucilaginous liquid. It has been used with success in the same disease by Dr. Rademacher, of Vienna, who recommends it in a number of other diseases having nothing in common. (*Ann. de Thérap.*, 1854.) Dr. J. B. Brown also bears very emphatic testimony to the value of nitrate of soda as a speedy and safe remedy in dysentery and dysenteric diarrhœa. (*Charleston Med. Journ.*, May, 1854, p. 398; from *North-Western Med. and Surg. Journ.*)

As nitrate of soda has been imposed upon our merchants for nitre, it may be useful to mention that the former salt may be distinguished by its giving rise to an orange-yellow flame when thrown on burning coals, and by the rhomboidal shape of its crystals; those of nitre being long six-sided prisms. B.

NITRITE OF ETHYL. *Nitrite of Oxide of Ethyl. Nitrous Ether.* This compound is here introduced, in order that the reader may be made acquainted with the results obtained by Dr. B. W. Richardson, in reference to its physiological action when inhaled. The mode of preparing it, its sensible and chemical properties, and its composition, have been already incidentally considered, under Spiritus Ætheris Nitrosi (see *page* 1404), of which it is the characteristic ingredient. The liquid in its pure state is so volatile as to require an admixture of a proportion of proper ether (say from 10 to 50 per cent.), in order that it may be duly manipulated. Its action, according to Dr. Richardson, is closely analogous to that of nitrate of amyl. (See *page* 1530.) Inhaled in the quantity of a grain, it induces a sense of fulness in the head, rapid action of the heart, and some suffusion of the surface. Animals, made to inhale air containing fifteen minims of the fluid diffused through a cubic foot, die almost instantly from suspended action of the heart; retaining, however, sensibility and consciousness to the last. The nitrite is, therefore, in no degree anæsthetic. After death, the lungs appear bloodless, almost as if washed free from blood with water; an effect ascribed by Dr. Richardson to the rapid contraction of the pulmonary capillaries. The muscles are also blanched. The colour of the blood is changed, the arterial having become very dark, and the venous of a deep chocolate tint; but coagulation takes place as usual. A curious effect on cold-blooded animals is that, after apparent death, the animal will sometimes recover spontaneously, even after an interval of nine days. If a young hot-blooded animal, a kitten, for example, be suddenly subjected to its influence, it will fall senseless, and apparently dead, without respiration, or any discoverable action of the heart; but, after a period of six or eight minutes, respiration and circulation are spontaneously renewed, and this condition may last so long as half an hour, when the animal again relapses into inertia, and positively dies.

In the human subject, after inhalation, there are extreme suffusion of the face, a sense of fulness of the head, a tendency to fall forward, rapid and painful respiration, and excessive rapidity in the action of the heart. The effects soon cease when the agent is withdrawn; but it may be readily conceived that a little excess of this action would prove fatal. (*B. and F. Medico-chir. Rev.*, July, 1867, p. 259.) W.

NITRITE OF SODA. This salt at one time attracted attention, from the circumstance that, in the original edition of the British Pharmacopœia, it was employed in the preparation of Sweet Spirit of Nitre. As nitrite of soda contains the same acid that forms with oxide of ethyl, the nitrous ether, which is the basis of Sweet Spirit of Nitre, it was believed that a simplification of the process might be effected by distilling a mixture of the nitrite, sulphuric acid, and alcohol, and thus, through the liberation of the nitrous acid by the sulphuric, bringing the former directly to bear on oxide of ethyl produced by the action of the sulphuric acid on the alcohol. But the process failed, probably from the difficulty of obtaining the nitrite of soda pure; the British directions for the preparation of the nitrite yielding but a small proportion of that salt. In the revised Pharmacopœia, the process for Sweet Spirit of Nitre originally adopted was abandoned; and nitrite of soda has ceased to be an object of special interest. W.

NITROGLYCERIN. *Glonoin.* When equal parts of strong nitric and sulphuric acids are gradually added, in small portions at a time, and at a temperature kept below freezing, to glycerin, this is converted into a bright-yellow liquid, which has remarkable explosive properties, and has received the name at the head of this article. Nitroglycerin was discovered about 21 years ago, by Dr. Sobrero, now a Professor in Turin. It was afterwards made a subject of study by Dr. de Vrij, of the Netherlands, Dr. Gladstone, and Dr. Kopp; but did not attract general attention until after 1864, when its capacities as an explosive agent became known. It is a yellow liquid (said to be colourless or slightly yellowish when pure); of a sp. gr from 1·525 to 1·6; inodorous; of a sweet, pungent, aromatic taste; very slightly soluble in water, but readily soluble in ether, alcohol, and methylated spirit; not freezing above 4° F. when quite pure (J. R. Wagner), but, as it occurs in commerce, solidifying by continued exposure to a temperature of 46·4° F., and assuming the form of long needles, which it is dangerous to handle, as they explode violently when gently broken. In the liquid state, it does not inflame or explode by the mere contact of flame; but with concussion, or by touching it with a red-hot iron, it explodes with great vehemence. Detonating mixtures, or exploding gunpowder, in its near vicinity, produce the same effect. By keeping it undergoes partial decomposition; and, in confined vessels, the pressure of the accumulated gases which result is sometimes so great as to cause its explosion upon the slightest concussion. Its explosive force greatly exceeds that of gunpowder. According to Nobel, one measure of the fluid explodes into 10,384 measures of gas, while one measure of gunpowder yields only 800 measures. It has, therefore, been much employed in exploding rocks, in mining, quarrying, road-making, &c.; and its economical advantages have kept it in extensive use, notwithstanding the danger. Important inferences from these facts are, that it should not be kept in large quantities, nor conveyed to any considerable distance; and the most fearful consequences have followed a neglect of these precautions. Practical operators recommend that it should be made extemporaneously where wanted as an explosive agent.

Nitroglycerin is formed by the substitution of three eqs. of hyponitric acid (NO_4) for three of the eqs of hydrogen of the glycerin. Its formula, therefore, is $C_6H_5O_6.3NO_4$; or, supposing glycerin to be a hydrate of glyceryl ($C_6H_7O_5+HO$), and the substitution to take place in the radical exclusively, $C_6H_4O_5.3NO_4+HO$. Among the products of the explosion of nitroglycerin, are glycerin, oxalic and hydrocyanic acids, ammonia, and others unknown. (A. Adriani, *Chem. News*, Jan. 3, 1868, p. 11.) Hence it may be inferred that the dangers from its explosion are not only those from mechanical violence, but also from the inhalation of its vapours.

M. E. Kopp gives the following as his method of preparing nitroglycerin on the spot where it is needed. First, fuming nitric acid, of the sp. gr. 1·51 to 1·53, is mixed with twice its weight of the strongest sulphuric acid. At the same time commercial glycerin, free from lead and lime, is evaporated in a pot to 30° or 31° Baumé, so that, on cooling, it shall have a syrupy consistence. Into 3300 grammes of the acid mixture, contained in a glass or porcelain capsule, placed in a trough of cold water, 500 grammes of the prepared glycerin are slowly poured with constant stirring; great care being taken to prevent any sensible heating of the mixture. The whole is then to be left for five or ten minutes, after which the mixture is to be poured into five or six times its volume of cold water, to which a rotatory motion has been given. The nitroglycerin precipitates rapidly in the form of a heavy liquid, which is separated by decantation, then washed with a little water which is decanted, and lastly is put into bottles. In this state it still contains a little acid and water; but these do not interfere with its use as an explosive agent.

Effects on the System. Nitroglycerin appears to act as a powerful but temporary stimulant both to the circulatory and nervous systems, causing increased frequency of pulse and severe headache, followed, if the dose is considerable, by symptoms of prostration, which are alarming from overdoses; but we have met with no account of a fatal termination in any instance. As a local application it is said to have little effect; and, to operate on the system, it must be absorbed. The idea has been suggested that nitrous oxide might be one of the results of its decomposition, and the cause of the symptoms; but these differ materially from the known effects of that agent. The dose required to affect the system is very small. Mr. J. M. Merrick experienced decided effects from one-fortieth of a drop; and, in a case recorded by Mr. Field, a temporary loss of consciousness and other alarming symptoms of narcotic poisoning are said to have been produced by about the forty-fifth of a drop. Yet two drops of the poison have been taken with no other effect than slight confusion of the head; so that the drug would seem to be of extremely uncertain operation. Mr. B. Sepuchardt, of Hanover, made experiments on himself, with the following results. Taking a single drop, he felt, five minutes afterwards, a great deal of giddiness, attended with weakened vision, headache with throbbing in the temples, a sense of weariness, sleepiness, a strong aromatic taste in the mouth, burning in the throat, and severe pain in the cardiac region. An hour afterwards, these symptoms having subsided, he was attempting to take another dose from a bottle of the nitroglycerin by means of a glass tube, when accidentally a large quantity entered the fauces; and, though he discharged most of it from the mouth, he must have swallowed a considerable portion, perhaps as much as ten drops. The previous symptoms returned so severely that he was compelled to lie down; and a half unconscious condition came on, which lasted several

hours, and left behind it a violent throbbing headache, sensitiveness to light, giddiness, and universal trembling. At first there was increased heat and frequency of pulse, afterwards a feeling of coldness, with a burning sensation in the region of the heart, and nausea, but no vomiting. There were no symptoms of a convulsive character. Next day the effects had entirely ceased. (*Am. Journ. of Pharm.*, March, 1867, p. 164; from the *Zeitschrift für praktische Heilkund. Medicinal.*, heft 1.) Inhalation of the vapour produces similar effects. Mr. Merrick experienced intense headache from this cause, with intolerance of light, and feelings of general distress, faintness, and exhaustion. (*Ibid.*, Nov. 1863, p. 564.) The same symptoms have been experienced by workmen engaged in its preparation and use. Few trials have as yet been made with it therapeutically; and its precise effects are not sufficiently well understood to justify its use, except experimentally and with great caution. Trials with the drug on animals have shown that relatively very large doses are necessary to cause death. W.

NITROPRUSSIDE OF SODIUM. This is the most interesting of a series of salts, discovered by Dr. Playfair, called *nitroprussides*, which are produced, for the most part, by saturating *nitroprussic acid*, formed by the action of nitric acid on ferrocyanide of potassium, with different bases. The sodium salt is best obtained by the process of A. Overbeck, as follows. Dissolve *four parts* of powdered ferrocyanide of potassium, contained in a flask, in *five and a half parts* of commercial nitric acid, diluted with an equal weight of water. After the action is completed, which generally occupies about ten minutes, and is accompanied by a copious evolution of gases, heat the resulting coffee-brown liquid in a water-bath, until a drop of it gives a dingy green, instead of a blue precipitate, with a solution of sulphate of protoxide of iron. Then allow the liquid to cool; whereupon the larger part of the nitrate of potassa generated will be deposited in crystals. Pour off the green mother-liquor from these, and separate the remaining nitrate of potassa by repeated concentrations. Next neutralize the liquid, while heated in a water-bath, with carbonate of soda, taking care to add the carbonate so long only as a pure blue precipitate is produced. Lastly, filter the solution, and set it aside for the formation of crystals, which must be washed with water, and dried between blotting-paper. (*Chem. Gaz.*, July 15, 1853, p. 271.) This salt is in the form of large, ruby-coloured, prismatic crystals, very much resembling those of ferridcyanide of potassium (red prussiate of potassa). It is soluble in two and a half parts of cold water, and in a less quantity of hot water. Its solution, exposed to sunshine, is decomposed, with evolution of nitric oxide gas, and deposition of Prussian blue, at the same time acquiring a green colour. Nitroprusside of sodium, as well as the other soluble nitroprussides, is a most delicate test for the alkaline sulphurets, with which it strikes a beautiful violet colour. Its composition is not certainly known; but the following formula, given by Gerhardt, is probably the correct one: $Na_2Fe_2Cy_5NO_2+4HO$. Nitroprussic acid is the nitroprusside of hydrogen, with the formula $H_2Fe_2Cy_5NO_2$. B.

NITROSULPHATE OF AMMONIA. This compound, discovered by Pelouze in 1835, may be formed by passing nitric oxide through a solution of sulphate of ammonia in five or six times its volume of water of ammonia. A large number of crystals are formed, which must be quickly washed with water of ammonia previously refrigerated, and dried without heat. Nitrosulphate of ammonia has been used at the Hôtel-Dieu in Paris, in doses of twelve grains, with apparent advantage, in typhoid fever. Its composition corresponds with one eq. of nitric oxide, one of sulphurous acid, and one of ammonia; but as the salt is not precipitated by barytic water, Pelouze conceives that the nitric oxide and sulphurous acid, together, form a peculiar acid, which he calls *nitrosulphuric acid*, consisting of one eq. of nitrogen, one of sulphur, and four of oxygen (NSO_4). B.

NITROUS OXIDE. *Protoxide of Nitrogen. Laughing Gas.* These names have been given to a gaseous substance, discovered by Priestly in 1776, but first brought into general notice in 1800 by Sir Humphry Davy, who discovered and made known the remarkable exhilarating properties which earned for it the name of laughing gas.

Preparation. In its preparation, nitrate of ammonia, in its purest state, is submitted in a glass retort to a heat sufficient to decompose it, not exceeding 400° F.; and the resulting gas and vapour are collected in a glass receiver over warm water, or a saturated aqueous solution of common salt. Warm water is preferred because cold water absorbs much of the gas, and would consequently occasion loss; and even warm water, though it takes up much less, is not entirely unobjectionable on this score; and the saline solution is therefore probably, on the whole, best adapted to the purpose. When nitrate of ammonia is heated to the point of decomposition, it is wholly resolved into watery vapour and nitrous oxide; the nitric acid giving three of its five eqs. of oxygen to the three eqs. of hydrogen of the ammonia, to form three eqs. of water, and being itself reduced to the state of nitric oxide or deutoxide of nitrogen, which is then converted into the nitrous oxide or protoxide of nitrogen, by combining with the single eq. of nitrogen of the ammonia which had been set free. But it is necessary not to let the heat employed be too high, as otherwise, besides nitrous oxide, there will come over portions of nitric oxide, uncombined ammonia, and probably even nitric acid, which contaminate the product, and render it unfit for use. This may be avoided by arresting the process as soon as any white fumes appear in the retort. Peculiar care also must be taken that the nitrate of ammonia should be pure, and especially free from muriate of ammonia,

which might cause an admixture of chlorine in the product. To ensure against impurities of this kind, it is best in any case in the least doubtful, and perhaps it might be best in all cases, to cause the nitrous oxide, before it is used by inhalation, to pass successively through two solutions; one of protosulphate of iron, to remove any nitric oxide that might be present; the second, of caustic potassa or soda, to neutralize acid impurities and chlorine.

Properties. Nitrous oxide gas is colourless, nearly or quite inodorous, slightly sweetish to the taste, and of the sp. gr. 1·527. Cold water will absorb about three-fourths of its bulk of the gas, and, under pressure, much more; and, thus impregnated, has a slight, not unpleasant smell, and sweetish taste. By the joint influence of cold and pressure the gas may be condensed into a liquid, which is colourless, very mobile, and capable, under the ordinary atmospheric pressure, of remaining liquid at 9° F. The liquefaction was effected by M. Bianchi at 32° F., under a pressure of thirty atmospheres. (*Am. Journ. of Pharm.*, July, 1865, p. 275.) Inflammable bodies will generally burn with increased vigour in nitrous oxide, which is capable also of supporting life for a time when respired, by giving oxygen to the blood. It consists of one eq., each, of nitrogen and oxygen, and its formula is NO.

For use it may be kept in two states, according as it is to be used by inhalation or by the stomach; the gaseous, namely, and the liquid. In the former state, it is best kept in gasometers, from which it may be readily transferred to bags when wanted for inhalation; though, even for this purpose, it may not be amiss to follow the plan, suggested by Dr. Ziegler, of compressing it in water, which may be made to absorb five times its bulk, and when the gas is needed, will readily give it up if heated. More will be said in a subsequent page of the liquid form in which it is kept for internal use.

Effects on the System. Nitrous oxide is a general stimulant, with a special direction to the brain and nervous system generally. When inhaled, it very speedily excites the cerebral functions, exhibiting its effects in exhilaration of the spirits, often attended with laughter, the occurrence of various delusions, and a strong tendency to muscular action, not unfrequently leading to assaults on those around. It is said also sometimes to cause aphrodisiac excitement. Carried further it induces a loss of consciousness, with complete insensibility to pain, so that severe surgical operations may be performed unfelt by the patient. These effects quickly subside, leaving behind none of that depression, nausea, and general uneasiness so apt to follow the use of stimulant narcotics. This is one of the most extraordinary properties of nitrous oxide, forming an exception to the almost universal rule of depression following excitement; and explicable only on the supposition that, through its constituents, it immediately yields to the nerve-tissue nutritive material to supply the waste occasioned by its excessive action. No instance has yet been recorded, so far as we are aware, of fatal results from the action of nitrous oxide, though it might, no doubt, be pushed so far as to cause death.

Anæsthetic Use and Administration. The anæsthetic property of nitrous oxide, as well as its exhilarating influence, was discovered by Sir Humphry Davy, who even suggested that it might be used to prevent pain in surgical operations; but the first practical application of it to this purpose is due to the late Dr. Horace Wells, of Connecticut. Having occasion for the extraction of a tooth, Dr. Wells successfully tried, in his own person, the efficacy of the nitrous oxide in preventing the pain of the operation; and soon afterwards, as the result of his experiment, two surgical operations were performed under the same influence, and with the same success. The measure, however, so promising at the outset, seems to have been entirely neglected, until after the discovery of the anæsthetic properties of ether, and its introduction into surgery, in Boston. Sixteen or eighteen years after the experiment of Dr. Wells, the use of nitrous oxide as an anæsthetic was revived in New York by Mr. G. L. Colton, in its application to dentistry, and by Dr. J. M. Carnochan, of the same place, to surgery; and so successfully that, at the present time, it is admitted among the regular anæsthetic agents, exhibited by inhalation, and probably the safest of all of them. It is, however, liable to two objections, which, unless obviated, will prevent its universal use; one, the relative inconvenience of its application; the other, the brevity of its action. It cannot well be exhibited without the co-operation of the patient; and this is scarcely possible in those protracted operations in which the anæsthetic influence may require repeated renewal; and, in general, the higher surgical operations demand a longer anæsthesia than can be obtained by one administration of this gas. Nitrous oxide will, therefore, probably be confined to dentistry and to the shorter operations of the higher surgery; especially the former, as arrangements may be made, in the office of the dentist, for the preservation and convenient exhibition of the gas, which cannot always be commanded elsewhere.

But the inhalation of nitrous oxide as an anæsthetic agent is applicable not only in painful operations; but also to relieve violent attacks of pain, whether in the form of neuralgia or spasm; as in tic douloureux and severe gastrodynia, enteralgia, nephralgia, &c. Its stimulant influence, in the same way, may also often be resorted to, independently of any painful complication, in various low forms of disease in which a sudden and powerful impression is required, as in malignant chill, sudden prostration occurring in the low forms of fever, and in protracted syncope. The difficulty of administration, however, forms an objection, which, in many of these cases, is at present insurmountable.

The common mode of exhibition is by means of an air-tight bladder or bag, with a tube and mouth-piece attached. The patient, with his nostrils closed, inhales the air from the bag, into which the expired air returns; so that, when the administration is somewhat protracted, the air in the bag becomes contaminated, and at length insufficient to support life. In such cases, the bag should be removed; or an instrument may be resorted to, in which, by a proper arrangement of valves, the inspired air may come from the bag, and that expired be allowed to escape by a different outlet. The capacity of the bag is often not more than one or two gallons; but, to obviate, in some measure, the inconvenience alluded to, it may be made to contain several gallons, three or four, for example, or according to Dr. Spear, six or eight gallons. The period at which the anæsthetic effect is produced varies greatly. It may occur at the end of two or three minutes, or may be postponed a good deal longer; much depending, in this respect, on the ability of the patient to take a full breath. The effect is said to have been produced after three deep and prolonged respirations; and sometimes twenty are required where any impediment may exist to a free expansion of the lungs. For the figure of an apparatus, combining the means of preparation, the reception and preservation in a gasometer, and the means of exhibition, suitable for a dentist's office, see the *American Journal of Pharmacy* (Sept. 1868, p. 412). W.

Nitrous Oxide Water. Water, impregnated by pressure with about five times its volume of this gas, forms the *nitrous oxide water*, known in England under the name of *Searle's patent oxygenous aërated water*, which has been used to some extent as an internal remedy. Sir H. Davy tried the aqueous solution, made without pressure, and thought it acted as a diuretic, and promoted digestion; and Sérullas used it in Asiatic cholera with apparent advantage. The patent water is asserted to be suited to the treatment of torpor, debility, depression of spirits, asthma, and dyspepsia; but to be contraindicated in inflammatory and plethoric states of the system. Dr. George J. Ziegler, of Philadelphia, has made a number of therapeutic trials with nitrous oxide water, charged with five times its volume of the gas, and finds it to possess tonic, resolvent, exhilarant, and diuretic properties. He has observed, however, that its free and prolonged use is apt to produce emaciation. Dr. Ziegler has also made some interesting experiments, tending to show the antidotal and revivifying properties of nitrous oxide. In these experiments dogs were asphyxiated or poisoned with carburetted hydrogen, chloroform, carbonic acid, hydrocyanic acid, and other agents, and, when in a state of suspended animation more or less complete, were generally revived by the nitrous oxide water, injected into the bowels in the quantity of from two to three pints. When administered by the stomach, the dose of the water is from half a pint to a pint and a half, taken in the course of the day. Dr. Ziegler concludes from his observations and experiments that nitrous oxide is a powerful arterial, nervous, and cerebral stimulant, possessing, at the same time, valuable antidotal powers, (*Bost. Med. and Surg. Journ.*, xlvi. 453, and xlvii. 383.)* Dr. Chapelle, of Angouleme, in France, has found this remedy especially useful in *lypomania*, or that form of monomania, in which the delusion is attended with melancholy. B.

NYMPHÆA ODORATA. *Sweet-scented Water-lily.* An indigenous herbaceous perennial, growing in most parts of the United States, in fresh-water ponds and on the borders of streams, and distinguished by the beauty and delicious odour of its large, white, many-petaled flowers. Its root is large and fleshy in the recent state, but becomes light, spongy, and friable by drying. It is very astringent and bitter, and, according to Dr. Bigelow, contains much tannin and gallic acid. It is sometimes employed, in the form of poultice, as a discutient application. The root of the *Nymphæa alba*, or European *white water-lily*, was esteemed antaphrodisiac by the ancients, but has long lost this reputation. Like that of the American plant, it is bitter and styptic, and may have been useful by its astringency in some cases of leucorrhœa, gonorrhœa, dysentery, &c., in which it was formerly employed for its reputed sedative virtues. W.

OCHRES. These are native mixtures of argillaceous or calcareous earth and oxide of iron, employed in painting. They are prepared for use by agitating them with water, decanting the turbid liquor after the coarser particles have subsided, then allowing it to rest in order that the finer parts may be deposited, and, lastly, drying the sediment which forms. The colour of the ochres varies with the state of oxidation of the iron, and with the proportion which it bears to the other ingredients, and is sometimes artificially modified by the agency of heat. Several varieties are kept in our shops under different names, according to their colour or place of origin. Such are the *brown ochre*, the *yellow ochre*, the *red ochre*, the *Roman ochre* of a brownish-yellow changing by heat to a purple-red, the *Oxford ochre* of a brownish-yellow colour less deep than the Roman, and the *French ochre* which is yellow. The *Indian red* from the Persian Gulf, and the *Spanish brown* may also be ranked in this class of pigments. Sometimes ochres come in a powdery state, and sometimes in hard masses; in the latter state they are called *stone ochres*. W.

OCYMUM BASILICUM. *Basil.* An annual plant, a native of India and Persia, and cultivated in Europe and in this country in gardens. The whole plant has a strong, peculiar, agreeable, aromatic odour, which is improved by drying. The taste is aromatic, and

* In a letter addressed to one of the authors by Mr. R. C. Clark, it is stated that the writer had been effectually cured of severe neuralgia by taking a fluidounce of the nitrous oxide water every six hours.

somewhat cooling and saline. It yields by distillation a yellowish-green volatile oil, lighter than water, which on being kept solidifies into a crystalline camphor, isomeric if not identical with turpentine-camphor. (*Gmelin's Handbook*, xiv. 359.) Basil has the ordinary properties of the aromatic plants, and is in some places considerably used as a condiment. The seeds are said by Ainslie to be used in India, in the form of infusion, as a remedy in gonorrhœa and nephritic affections. W.

ŒNANTHE CROCATA. *Hemlock Water-dropwort.* A perennial, umbelliferous, aquatic European plant, exceedingly poisonous both to man and inferior animals. The root, which has a sweetish not unpleasant taste, is sometimes eaten by mistake for other roots, with the most dangerous effects; and numerous instances of fatal results are on record. The symptoms produced are such as attend irritation or inflammation of the stomach, united with great cerebral disturbance, indicated by giddiness, convulsions, and coma. Externally applied, the root produces redness and irritation of the skin, with an eruptive affection. It is said to be sometimes used empirically as a local remedy in piles; and a case is recorded in which an obstinate leprosy was cured by the continued use of the juice of the plant. Other species of *Œnanthe* are poisonous, and the whole genus should be regarded among the suspected plants. We have two or three indigenous species. The proper remedies, in cases of poisoning from these plants, are emetics, followed, after the stomach has been thoroughly evacuated, by demulcent drinks. A peculiar resinoid principle, denominated *œnanthin*, has been found by Mr. Gerding in *Œnanthe fistulosa*, of which half a grain, given to an adult, produced long-continued irritation of the fauces, with hoarseness, and a grain occasioned vomiting. (See *Am. Journ. of Pharm.*, xxi. 68.) W.

ŒNANTHE PHELLANDRIUM. (Sprengel.) *Phellandrium aquaticum.* Linn. *Fine-leaved Water-hemlock.* A biennial or perennial, umbelliferous, European water-plant, the fresh leaves of which are said to be injurious to cattle, producing a kind of paralysis when eaten. By drying, they lose their deleterious properties. The *seeds* have been used in Europe to a considerable extent in the treatment of disease. They are from a line to a line and a half in length, ovate-oblong, narrow above, somewhat compressed, marked with ten delicate ribs, and crowned with the remains of the calyx, and with the erect or reverted styles. Their colour is yellowish-brown; their odour peculiar, strong, and disagreeable; their taste acrid and aromatic. Among their constituents is a volatile oil, upon which their aromatic flavour depends. By Mr. C. Fronfield it has been rendered probable that they contain a volatile alkaloid, analogous to conia, if it be not conia itself; for if the powdered seeds are rubbed with solution of potassa, the peculiar mouse-like odour of that alkaloid is exhaled. The powder was submitted to distillation with caustic potassa, the alkaline liquid obtained was neutralized with sulphuric acid and evaporated to a syrupy consistence, alcohol was added to precipitate the sulphate of ammonia, the liquid was then filtered, treated with caustic potassa, and again distilled. On the surface of the distillate a yellow oily fluid floated, which was only slightly soluble in water but readily so in ether and alcohol, evinced an alkaline reaction with turmeric paper, and neutralized the alkalies. (*Am. Journ. of Pharm.*, May, 1860, p. 211.) By different writers the seeds are described as aperient, diuretic, emmenagogue, expectorant, and sedative. They probably unite mild narcotic properties with the stimulant powers which are common to most of the aromatics, and may be directed, according to circumstances, to different secretory organs. In overdoses they produce vertigo, intoxication, and other narcotic effects. They appear to have been used most successfully in chronic pectoral affections, such as bronchitis, pulmonary consumption, and asthma. They have been given also in dyspepsia, intermittent fever, obstinate ulcers, &c. The dose of the seeds, to commence with, is five or six grains, so repeated as to amount to a drachm in twenty-four hours. They should be given in powder. A tincture and alcoholic extract have been prepared, of which the former, containing the virtues of half a drachm of the seeds in a fluidounce, is given in a dose varying from half a fluidrachm to a fluidrachm, and the latter in that of three to five grains. (*Pharm. Journ.*, xii. 591.) W.

ŒNOTHERA BIENNIS. *Tree Primrose.* A biennial indigenous plant, growing in fields and along fences from Canada to the Carolinas. It is from two to five feet high, with a rough stem, alternate, ovate-lanceolate leaves, and fine yellow flowers, which make their appearance in July and August. Schoepf states that it is esteemed useful as a vulnerary. The late Dr. R. E. Griffith found a strong decoction of the small branches, with the leaves and cortical part of the stem and larger branches, very beneficial in eruptive complaints, especially tetter. He applied the decoction several times a day to the affected part. He believed the virtues of the plant to reside in the cortical part, which has a mucilaginous taste, and leaves a slight sensation of acrimony in the fauces. W.

OIL OF ANDA. A fixed oil procured by expression from the seeds of *Anda Brasiliensis* (Radde), *Anda Gomesei* (Ad. Jussieu), a tree of Brazil, belonging to the family of Euphorbiaceæ. The bark yields on being wounded a milky juice, which is said to be poisonous, and to be used for stupefying fish. The fruit, which is about as large as an apple, ash-coloured, with two larger and two smaller angles, encloses a two-celled nut, containing two seeds, about the size of a chestnut. Like the seeds of other Euphorbiaceous plants,

these are actively purgative; one seed, according to Martius, being the dose for a man. By expression these seeds yield a pale-yellow, transparent oil, with little smell or taste, which is said to be used in Brazil for burning and painting. Dr. Norris, who tried the oil at the Pennsylvania Hospital, found it to operate on the bowels moderately in the dose of fifty drops, and copiously, when more largely given. (*Cyclopædia of Prac. Med. and Surg.*, i. 470.) Dr. Alexander Ure, who has experimented with it in several cases, states that, in the average dose of twenty drops, it usually operates mildly, without producing heat or pain in the throat, and seldom causing nausea or vomiting. W.

OIL OF BEN. This is a fixed oil extracted from the seeds of the *Moringa pterygosperma* and *M. aptera* of *Gærtner*, confounded by Linnæus under the name of *Guilandina Moringa*. *Hyperanthera Moringa* (Vahl) is a synonyme of the former species. These are trees belonging to the family of *Leguminosæ*, inhabiting different parts of India, Arabia, Syria, &c., and introduced into the W. Indies. Mr. James Macfadyen, in his *Flora of Jamaica* (i. 325), states that it is not the M. pterygosperma which yields the commercial oil of ben, but the M. aptera, which has not been introduced into Jamaica. He says, however, that an excellent and palatable oil may be obtained by expression from the seeds of M. pterygosperma, growing in that island. The leaves and other parts have an acrid property, which has probably given the name of *horse-radish tree* to M. pterygosperma. The oil of the seeds has long been known, though used rather in the arts than in medicine. It is prepared in Europe from the seeds brought from Egypt (*Mérat et De Lens*); and it would appear, from the statements of Mr. Macfadyen, that the idea generally prevailing that it is also extracted in the W. Indies is incorrect. The oil is inodorous, clear, and nearly colourless, and keeps long without becoming rancid. It is employed for similar purposes with olive oil. Mérat and De Lens say that it is purgative; but most of the fixed oils are so in sufficient doses. According to Völcker, the oil contains margarin, olein, and a peculiar fatty matter yielding an acid by saponification, which he names *benic acid*. (*Journ. de Pharm.*, xvi. 77.) W.

OIL OF CADE. *Oleum Cadinum. Huile de Cade.* French. This is a kind of tar, obtained by distillation, *per descensum*, from the interior reddish wood of *Juniperus communis*, or more strictly of *J. Oxycedrus*, which grows in the South of France, where the substance is prepared. It is a thick liquid, black, and of a smell analogous to that of common tar. It has long been employed in the treatment of the cutaneous diseases of horses, sheep, &c.; and is also applied by the peasantry to their own skin affections. More recently, it has acquired much reputation in these complaints, in consequence of its extensive and successful use in the hospitals of Paris. M. Bazin has employed it with success in psora, lichen agrius, the different scaly affections, the advanced stage of eczema, and favus. In most of these complaints we have long been in the habit of employing common tar ointment, and with probably equal success. A kind of soap is prepared from the oil of cade, which affords a convenient method of applying it. In the *Ed. Monthly Journ.* for July, 1852 (*page* 66), it is stated that the soap is made by distilling the tar, incorporating the volatile oil obtained with a fixed oil, and then saponifying this with soda. It is in the form of black balls, readily unites with water, and may be applied to the surface like any other soap. The best plan is probably to apply it at bedtime, and wash it off next morning. A *glycerate of the tar* has been recommended for external use, made by mixing, with the aid of heat, an ounce of glycerin, half a drachm of the purified oil of cade, and half an ounce of powdered starch. (See *Am. Journ. of Med. Sci.*, Jan. 1859, p. 228.) W.

OIL OF EUPHORBIA. A fixed oil, obtained from the seeds of *Euphorbia Lathyris*, a biennial plant growing wild in this country, though believed to have been introduced from Europe. It is often found near gardens and in cultivated fields, and is generally called *mole plant*, under the impression that moles avoid the grounds where it grows. (*Pursh.*) It is the *caper plant* of England. (*Loudon's Encyc. of Plants.*) Like the other species of Euphorbia, it contains a milky juice, which is extremely acrid; and the whole plant possesses the properties of a drastic purge; but the oil of the seeds is the only part used in regular practice. This may be extracted by expression, or by the agency of alcohol or ether. In the first case, the bruised seeds are pressed in a canvass or linen bag, and the oil which escapes is purified by decanting it from the whitish flocculent matter which it deposits upon standing, and by subsequent filtration. By the latter process, the bruised seeds are digested in alcohol, or macerated in ether, and the oil is obtained by filtering and evaporating the solution. According to Soubeiran, however, the oils obtained by these different processes are not identical. That procured by expression is probably the purest.

Oil of euphorbia is colourless, inodorous, and, when recent, nearly insipid; but it speedily becomes rancid, and acquires a dangerous acrimony. Soubeiran has ascertained that it has a complex composition, containing, besides the pure oil, four distinct proximate principles. (*Journ. de Pharm.*, xxi. 259.) From 40 to 44 parts are obtained by expression from 100 of the seed. It is a powerful purge, operating with much activity in a dose varying from five to ten drops. It was, some years since, much used by certain Italian and French physicians, who did not find it to produce inconvenient irritation of the stomach and bowels Its want of taste, and the smallness of the dose, recommended it especially in the cases of infants. It was said to be less acrid and irritating than the

croton oil, over which it also has the advantage of greater cheapness. Some trials made with it on this side of the Atlantic have not confirmed these favourable reports. It was found uncertain in its cathartic effect, and very liable to vomit. (Scattergood, *Journ. of the Phil. Col. of Pharm.*, iv. 124.) It may be given in pill with the crumb of bread, or in emulsion. W.

OIL OF JASMINE. This oil is obtained from the flowers of *Jasminum officinale* or *common white jasmine*, and from those also of *J. Sambac* and *J. grandiflorum*. Alternate layers of the fresh flowers, and of cotton saturated with the *oil of ben* (see *page* 1659), or perhaps other fixed oil, are exposed in a covered vessel to the warmth of the sun; the flowers being occasionally renewed till the oil becomes impregnated with their odour, when it is separated from the cotton by pressure. This method is necessary, as the flowers do not yield their aroma by distillation. The oil is used only as a perfume.

In the *Medical and Surgical Reporter* (Jan. 5, 1861) the case of a child is recorded, under the care of Dr. W. H. Hall, of Brooklyn, N. Y., who was severely poisoned by eating the fruit of a species of Jasmine, growing in the garden, probably the common white jasmine above referred to. The symptoms were those of an energetic narcotic; as coma, largely dilated pupil, and snoring respiration, with a cold pale surface, and slow and feeble pulse, followed by violent convulsions, with rigidity of the muscles about the head and throat. Under the use of the hot-bath, with active emetics, the spasms relaxed, vomiting took place, and the patient, though feeble for a few days, ultimately recovered his wonted health. (*B. and F. Medico-chirurg. Rev.*, April, 1861, p. 283.) W.

OLIBANUM. Olibanum, the *frankincense* of the ancients, was erroneously ascribed by Linnæus to *Juniperus Lycia*. There appears to be two varieties, one derived from the countries bordering on the Red Sea, and taken to Europe by way of the Mediterranean, the other brought directly from Calcutta. In reference to the tree producing the former there is some uncertainty. Captain Kempthorne, of the E. India Company's Navy, saw it growing upon the mountains, on the African coast, between Bunder Maryah and Cape Guardafui. According to his statement, it grows on the bare marble rocks composing the hills of that region, without any soil or the slightest fissure to support it, adhering by means of a substance thrown out from the base of the stem. This rises forty feet, and sends forth near the summit short branches, covered with a bright-green, singular foliage. The juice, which exudes through incisions made into the inner bark, has at first the colour and consistence of milk, but hardens on exposure. (*Pharm. Journ.*, iv. 37.) Sir Wm. J. Hooker says that the African olibanum is derived from *Plösslea floribunda* of Endlicher (*Boswellia*, Royle); but thinks it highly probable that it is furnished by more than one species. (*Ibid.*, Oct. 1859, p. 217.) The India olibanum has been satisfactorily ascertained to be the product of *Boswellia serrata* of Roxburgh, a large tree growing in the mountains of India, and found by Mr. Colebrook abundant in the vicinity of Nagpur. The tree belongs to the class and order *Decandria Monogynia*, and the natural order *Terebintaceæ* of Kunth.

The Arabian or African frankincense is in the form of yellowish tears, and irregular reddish lumps or fragments. The tears are generally small, oblong or roundish, not very brittle, with a dull and waxy fracture, softening in the mouth, and bearing much resemblance to mastic, from which, however, they differ in their want of transparency. The reddish masses soften in the hand, have a stronger taste and smell than the tears, and are often mixed with fragments of bark, and small crystals of carbonate of lime.

The Indian frankincense, or olibanum, consists chiefly of yellowish, somewhat translucent, roundish tears, larger than those of the African, and generally covered with a whitish powder produced by friction. It has a balsamic resinous smell, and an acrid, bitterish, somewhat aromatic taste. When chewed it softens in the mouth, adheres to the teeth, and partially dissolves in the saliva, which it renders milky. It burns with a brilliant flame, and a fragrant odour. Triturated with water, it forms a milky imperfect solution. Alcohol dissolves nearly three-fourths of it, and the tincture is transparent. From 100 parts, Braconnot obtained 8 parts of volatile oil, 56 of resin, 30 of gum, and 5·2 of a glutinous matter insoluble in water or alcohol, with 0·8 loss. Various saline substances were found in its ashes. The oil may be separated by distillation, and resembles that of lemons in colour and smell. According to Stenhouse, it is isomeric with oil of peppermint, having the formula $C_{35}H_{28}O$, and consists of an oxygenous and non-oxygenous oil. (*Gmelin's Handbook*, xiv. 390.)

Dr. W. F. Daniell has described an odorous product, used as *frankincense* in Sierra Leone, and obtained from a large tree, growing in the mountainous districts of that region. The tree has been described by Mr. John J. Bennett in the *Pharmaceutical Journal* for December, 1854 (p. 251), under the name of *Daniellia thurifera*. According to Dr. Daniell, the juice exudes through openings made by an insect, and, concreting in connection with the woody particles resulting from the boring of the insect, falls at length to the ground, where it is collected by the negroes. (See *Am. Journ. of Pharm.*, xxvii. 338.)

Olibanum is stimulant like the other gum-resins; but is now very seldom used internally. M. Delioux, of Toulon, however, is in the habit of using it for the same purposes as the balsams of Tolu and Peru, having satisfied himself by much experience that it produces similar effects, while it is less costly. He gives it, in the form of pill, in the medium dose of fifteen grains, which may be increased to a drachm or more. It appears

to act more favourably when combined with a little soap. He has also obtained advantage from the inhalation of its fumes, when heated, in chronic bronchitis and laryngitis. (*Bullet. Gén. de Thérap.*, Fev. 28, 1861.) It is chiefly employed for fumigation, and enters into the composition of some unofficinal plasters. W.

ONION. *Cepa.* The bulb of *Allium Cepa.* This is a perennial bulbous plant, with a naked scape, swelling towards the base, exceeding the leaves in length, and terminating in a simple umbel of white flowers. The leaves are hollow, cylindrical, and pointed. The original country of the onion is unknown. The plant has been cultivated from time immemorial, and is now diffused over the whole civilized world. All parts of it have a peculiar pungent odour, but the bulb only is used. This is of various size and shape, ovate, spherical, or flattened, composed of concentric fleshy and succulent layers, and covered with dry membranous coats, which are reddish, yellowish, or white, according to the variety. It has, in a high degree, the characteristic odour of the plant, with a sweetish and acrid taste. Fourcroy and Vauquelin obtained from it a white acrid volatile oil containing sulphur, albumen, much uncrystallizable sugar and mucilage, phosphoric acid both free and combined with lime, acetic acid, citrate of lime, and lignin. The expressed juice is susceptible of the vinous fermentation.

The onion is stimulant, diuretic, expectorant, and rubefacient. Taken moderately it increases the appetite and promotes digestion, and is much used as a condiment; but in large quantities it is apt to cause flatulence, gastric uneasiness, and febrile excitement. The juice is occasionally given, made into syrup with sugar, in infantile catarrhs and croup, in the absence of much inflammatory action. It is also recommended in dropsy and calculous disorders. Deprived of its essential oil by boiling, the onion becomes a mild esculent; and it is much more used as food than as medicine. Roasted and split, it is sometimes applied as an emollient cataplasm to suppurating tumours. W.

OPOPANAX. The concrete juice of *Pastinaca Opopanax* (Willd.), *Opopanax Chironium* (De Candolle). This species of parsnep, usually called *rough parsnep*, has a thick, yellow, fleshy, perennial root, which sends up annually a strong branching stem, rough near the base, about as thick as a man's thumb, and from four to eight feet in height. The leaves are variously pinnate, with long sheathing petioles, and large, oblong, serrate leaflets, of which the terminal one is cordate, others are deficient at their base upon the upper side, and the whole are hairy on their under surface. The flowers are small, yellow, and form large flat umbels at the termination of the branches. The plant is a native of the Levant, and grows wild in the South of France, Italy, and Greece. When the base of the stem is wounded, a juice exudes, which, when dried in the sun, constitutes the opopanax of commerce. Some authors state that it is obtained from the root. A warm climate appears necessary for the perfection of the juice; as that which has been collected from the plant in France, though similar to opopanax, is of inferior quality. The drug is brought from Turkey. It is said to come also from the East Indies; but Ainslie states that he never met with it in any Indian medicine bazaar.

It is sometimes in tears, but usually in irregular lumps or fragments, of a reddish-yellow colour, speckled with white on the outside, paler within, and, when broken, exhibiting white pieces intermingled with the mass. Its odour is strong, peculiar, and unpleasant, its taste bitter and acrid. Its sp. gr. is 1·622. It is inflammable, burning with a bright flame. In chemical constitution it is a gum-resin, with an admixture of other ingredients in small proportion. The results of its analysis by Pelletier were from 100 parts, 33·4 of gum, 42 of resin, 4·2 of starch, 1·6 of extractive, 0·3 of wax, 2·8 of malic acid, 9·8 of lignin, 5·9 of volatile oil and loss, with traces of caoutchouc. Water by trituration dissolves about one-half of the gum-resin, forming an opaque milky emulsion, which deposits resinous matter on standing, and becomes yellowish. Both alcohol and water distilled from it retain its flavour; but only a very minute proportion of oil can be obtained in a separate state.

Opopanax was formerly employed, as an antispasmodic and deobstruent, in hypochondriasis, hysteria, asthma, and chronic visceral affections, and as an emmenagogue in suppression of the menses; but it is now generally regarded as a medicine of very feeble powers, and in this country is scarcely ever used. The dose is from ten to thirty grains. W.

ORANGE RED. *Orange Mineral. Sandix.* Red oxide of lead, prepared by calcining carbonate of lead. It is of a brighter colour than *minium*, and is used as a pigment. W.

ORIGANUM VULGARE. *Common Marjoram. Origanum.* This plant was officinal in the former U. S. and Ed. Pharmacopœias; but as the volatile oil which was ascribed to it, and for which it was chiefly valued, has proved to be really the oil of thyme, it has been omitted both in the present U. S. and the Br. Pharmacopœias, though, in consideration of its aromatic properties, it might well have been introduced into the Secondary Catalogue of the former. The genus *Origanum* belongs to Didynamia Gymnospermia in the Linnæan system, and to the natural family Lamiaceæ or Labiatæ, and is characterized as follows. "*Strobile* four-cornered, spiked, collecting the calyces. *Corolla* with the upper lip erect and flat, the lower three-parted, with the segments equal." (*Willd.*) Two species have been used in medicine, *O. Majorana*, or sweet marjoram, and *O. vulgare*, or common marjoram. The former grows wild in Portugal and Andalusia, and is cultivated as a garden herb in other parts of Europe, and in the United States. Some authors, how-

ever, consider *O. Majoranoides*, which is a native of Barbary, and closely allied to *O. Majorana*, as the type of the sweet marjoram of our gardens. *Sweet marjoram* has a pleasant odour, and a warm, aromatic, bitterish taste, which it imparts to water and alcohol. By distillation with water it yields a volatile oil, which was directed by the Edinburgh College among their preparations. It is tonic and gently excitant, but is used more as a condiment in cookery than as a medicine. In domestic practice, its infusion is much employed by the vulgar to hasten the tardy eruption in measles and other exanthematous diseases.

Origanum vulgare or *common marjoram* is a perennial herb, with erect, purplish, downy, four-sided, trichotomous stems, about eighteen inches high, and opposite, ovate, entire, somewhat hairy leaves, of a deep yellowish-green colour. The flowers are of a pinkish-purple or rose colour, disposed in roundish, panicled spikes, and accompanied with ovate reddish bractes, longer than the calyx. This is tubular and five-toothed, with nearly equal segments. The corolla is funnel-shaped, with the upper lip erect, bifid, and obtuse, the lower trifid, blunt, and spreading. The anthers are double, the stigma bifid and reflexed. The plant is a native of Europe and America. In this country it grows along the roadsides, and in dry stony fields and woods, from Pennsylvania to Virginia, and is in flower from June to October; but it is not very abundant, and is seldom collected for use. It has a peculiar, agreeable, aromatic odour, and a warm, pungent taste. These properties it owes to a volatile oil, which was formerly employed, but has been superseded, in great measure, if not altogether, by the oil of thyme. It may be separated by distillation with water. Origanum is gently tonic and excitant, and has been used in the form of infusion as a diaphoretic and emmenagogue, and externally as a fomentation; but it is at present little employed. W.

OROBANCHE VIRGINIANA. *Epifagus Americanus.* Nuttall. *Beech-drops. Cancer-root.* This is a parasitic, fleshy plant, with a tuberous, scaly root, and a smooth stem, branched from the base, from twelve to eighteen inches high, furnished with small ovate scales, of a yellowish or purplish colour, and wholly destitute of verdure. It is found in all parts of North America, growing upon the roots of the beech tree, from which it obtained its popular name. It is in some places very abundant. The plant has a bitter, nauseous, astringent taste, which is said to be diminished by drying. It has been given internally in bowel affections; but its credit depends mainly upon the idea that it is useful in obstinate ulcers of a cancerous character, to which it is directly applied in the state of powder. The late Professor Barton conjectured that it was an ingredient of a secret remedy, at one time famous as *Martin's cancer powder*, of which, however, the most active constituent was arsenious acid.

Other species of Orobanche, growing in America and Europe, have been employed. They are all parasitic, fleshy plants, without verdure, and of a bitter, nauseous taste. In Europe they are called *broom-rape*. The *O. Americana* and *O. uniflora*, of this country, are said to be used for the same purposes as the species above noticed, and like it are called *cancer-root*. W.

ORPIMENT. *King's Yellow.* A native tersulphuret of arsenic, consisting of one eq. of metal 75, and three eqs. of sulphur 48=123. It is in masses of a brilliant lemon-yellow colour, composed of flexible laminæ, and slightly translucent. It exists in various parts of the world, but is obtained for use from Persia and China. (*Guibourt.*) It is sometimes mixed with realgar, which gives it a reddish or orange hue. A similar sulphuret may be made artificially by passing sulphuretted hydrogen through a solution of arsenious acid in muriatic acid. There is reason to believe that neither the native sulphuret, nor the artificial, when prepared in the manner just mentioned and well washed, is poisonous, at least in a degree at all comparable to other arsenical compounds.

Artificial orpiment is prepared for use by fusing together equal parts of arsenious acid and sulphur. (*Turner.*) In Germany, according to Guibourt, it is prepared by subliming a mixture of these two substances. In this case, however, it retains a large portion of the acid undecomposed, and is therefore highly poisonous Guibourt found a specimen which he examined to contain 94 per cent. of arsenious acid, and only 6 per cent. of the tersulphuret.

Orpiment is an ingredient of certain depilatories. *Atkinson's depilatory* is said to consist of one part of orpiment and six parts of quicklime, with some flour and a yellow colouring matter. (*Ann. der Pharm.*, xxxiii. 348.) But this arsenical sulphuret is chiefly used in fireworks, and as a pigment. W.

ORYZA SATIVA. *Rice.* This is an annual plant, originally, perhaps, derived from the East Indies, but now cultivated in all parts of the globe where the climate and soil are adapted to its growth. Barth says, in his Travels (Am. ed., 1857, ii. 345), that it grows wild in Central Africa. The rice of commerce consists of the seeds of the plant deprived of their husk. Carolina rice was found by Braconnot to contain 85·07 per cent. of starch, 3·60 of gluten, 0·71 of gum, 0·29 of uncrystallizable sugar, 0·13 of fixed oil, 4·80 of vegetable fibre, 5·00 of water, and 0·40 of saline substances. This grain is highly nutritious, and of easy digestion, and constitutes the almost exclusive diet of whole nations. Being entirely free from laxative properties, it is admirably adapted to cases of weak bowels, in which there is a strong tendency to diarrhœa. Care, however, should be taken that it be boiled till it becomes soft. A decoction of rice, usually called *rice-water*, is a good nutri-

tive drink in fevers, and inflammatory affections of the bowels, lungs, and kidneys. There appears to be no ground for the opinion, entertained by some, that a diet of rice is injurious to the eyes. W.

OXALATE OF IRON. *Protoxalate of Iron.* In the *London Pharmaceutical Journal* (Jan. 1867, p. 423) is a communication addressed to the *Medical Press and Circular* (Nov. 28, 1867) by Mr. J. Emerson Reynolds, calling attention to the oxalate of the protoxide of iron, as a chalybeate possessing certain qualities which give it value in a therapeutical point of view. He speaks of it as being borne with remarkable ease by the stomach, as having little or no astringency, and as producing the usual constitutional effects of the chalybeates with sufficient rapidity. He prepares it by adding a solution of protosulphate of iron to an excess of solution of oxalate of ammonia containing a little free oxalic acid. A yellow precipitate is formed, which is the salt in question, and which should be well washed and dried. The excess of oxalic acid has the effect of holding in solution any peroxalate of iron that may be produced. Its formula is FeO,C_2O_3+4HO; and it contains, therefore, by weight, one-third, each, of protoxide of iron, anhydrous oxalic acid, and water. As thus prepared it is a fine powder, of a straw-yellow colour, almost destitute of taste, and singularly slow in the absorption of oxygen. It is but slightly soluble in water, easily acted on by the dilute acids, and decomposed by the alkalies and their carbonates.

In the *American Journal of Pharmacy* (Jan. 1868, p. 77) is a communication from Mr. G. G. C. Simms, stating that the oxalate of iron was in daily use in the District of Columbia, and well known there to physicians and pharmaceutists, and that it was originally brought to the notice of the profession by Dr. Geo. O. Shaeffer, Prof. of Chemistry in the National Medical College of the District. In a letter from Dr. Shaeffer it is said that, so long since as 1854, having had occasion to examine the oxalate of iron, he had been induced, by certain characters he found it to possess, to make trials with it therapeutically. It is a proto-salt of iron; but, being only slightly soluble, little disposed to change, and destitute of astringency, it is preferable to the soluble proto-salts, which are often too astringent, and liable to rapid alteration. His success was all that he could wish. In doses of two or three grains, three times daily, the protoxalate produced all the tonic effects of iron more rapidly than the other salts; while, instead of being astringent, it gave rise to natural and healthy passages in cases where constipation depended on want of tone in the bowels. Dr. Shaeffer had then taken measures to make his convictions of this chalybeate known in Washington, which accounts for the facts above mentioned by Mr. Simms.

In a subsequent paper in the *Am. Journ. of Pharm.* (March, 1868, p. 111), Mr. J. B. Moore offers the following formula for this preparation. Take of pure protosulphate of iron ʒxviij gr. xxxij (1112 grains); oxalic acid ʒviij gr. xxiv (504 grains); water three pints and a half. Dissolve the salt and acid separately, the former in two pints of the water, and the latter in the residuary pint and a half. Strain the solutions through muslin, mix them, and, after agitation, set the mixture aside that the precipitate may fall. Collect this on a filter, and, having washed it with water till the washings no longer have an acid reaction with litmus, dry it at a temperature not exceeding 120° F. The properties of the salt have already been stated, as well as the points in which it is preferable to the other chalybeates. The dose is two or three grains, and may be most conveniently given in the form of pill. W.

OXALIC ACID. *Acidum Oxalicum.* This acid is found both in animals and vegetables. It is generated occasionally in consequence of a diseased action in the kidneys, and deposited in the bladder as oxalate of lime, forming a peculiar concretion, called the *mulberry calculus*. In vegetables, it occurs in a free state in the bristles of the chick-pea (*Cicer arietinum*), combined with potassa as a supersalt in *Rumex acetosa* or common sorrel, and *Oxalis Acetosella* or wood-sorrel, and united with lime in several species of lichen, and in the roots of rhubarb, valerian, and several other plants. It is from the generic appellation *Oxalis* that it takes its name.

Preparation. The usual process for obtaining oxalic acid consists in decomposing sugar by nitric acid. Four parts of sugar are acted upon by twenty-four of nitric acid of the sp. gr. 1·24, and the mixture is heated so long as any nitric oxide is disengaged. A part of the carbon of the sugar is converted into carbonic acid by oxygen derived from the nitric acid, which is thereby partially converted into nitric oxide. The undecomposed nitric acid, reacting with the remaining elements of the sugar, generates oxalic and saccharic (oxalhydric) acids, the former of which crystallizes as the materials cool, while the latter remains in solution. The crystals being removed, a fresh crop may be obtained by further evaporation. The thick mother-water which now remains is a mixture of saccharic, nitric, and oxalic acids; and, by treating it with six times its weight of nitric acid, the greater part of the saccharic acid will be converted into oxalic acid. The new crop of crystals, however, will have a yellow colour, and contain a portion of nitric acid, the greater part of which may be got rid of by allowing them to effloresce in a warm place. From the experiments of Mr. L. Thompson, of Newcastle-on-Tyne, it appears probable that, in the reaction occurring between nitric acid and sugar, half the carbon of the latter is converted into carbonic acid, and the other half into oxalic acid.

The manufacturing chemists are said to obtain oxalic acid on a large scale by heating a mixture of 112 lbs. of sugar, 560 lbs. of nitrate of potassa, and 280 lbs. of sulphuric acid. The products are 135 lbs. of oxalic acid, and 490 lbs. of supersulphate of potassa, or *sal enixum*. (*L. Thompson.*)

Many substances, besides sugar, yield oxalic acid by the action of nitric acid; as molasses, rice, potato starch, gum, wool, hair, silk, and many vegetable acids. In every case in which it is thus generated, the proportional excess of oxygen which it contains, compared with every other organic compound, is furnished by the nitric acid. When the acid is obtained from potato starch, this is first converted into starch sugar by the action of sulphuric acid. The following is an outline of the process, as conducted on a large scale. The pulp of potatoes, obtained by rasping or other suitable means, is washed two or three times by stirring it well with water, allowing it to subside, and running off the water. It is then boiled for some hours with water in wooden boilers, lined with lead and heated by steam; a quantity of sulphuric acid being stirred in the mixture, equal to 2 per cent. of the weight of the potatoes employed. By this treatment the starch of the potatoes is converted into starch sugar; and the change is known to be completed, when a drop of tincture of iodine, added to a little of the boiling liquor, placed on a piece of glass, ceases to produce a purple colour. The product is then filtered through a horse-hair cloth, and the liquid which passes is carefully evaporated until a gallon of it weighs about fourteen pounds. This liquid consists of a concentrated solution of starch sugar, and is now ready for conversion into oxalic acid by the action of nitric acid. For this purpose it is placed in wooden boilers, lined with lead, eight feet square and three deep, and, having been mixed with the requisite proportion of nitric acid, is heated to a temperature of about 125° by means of steam, passed through a coil of lead pipe, until the decomposition is effected. The liquor is then drawn off by a syphon or cock into shallow lead-lined wooden coolers to crystallize. The crystals having formed, the mother-waters are drawn off for use in a subsequent operation. When the manufacture of the acid is conducted in vessels of the size just indicated, the density of the nitric acid should not be less than 1·20 nor higher than 1·27. If the nitric acid is used of undue strength, a part of the oxalic acid at first formed becomes converted into carbonic acid, to the no small diminution of the desired product. (*Chem. Gaz.*, March 15, 1852, p. 112.) The product of oxalic acid from a given quantity of saccharine material has been much understated. If properly treated with nitric acid, 100 lbs. of good sugar will yield from 125 to 130 lbs. of oxalic acid, and the same weight of molasses, from 105 to 110 lbs.

Certain organic substances yield oxalic acid when heated with potassa. Thus shavings of wood, if mixed with a solution of caustic potassa, and exposed to a heat considerably higher than 212°, will be partially decomposed, and converted into oxalic acid, which then combines with the alkali. At present much of the oxalic acid of commerce is obtained by heating saw-dust with a mixture of caustic soda and potassa. Soda alone will not generate the acid, and potassa is too costly to be used by itself for the purpose; but Mr. Dale ascertained that by mixing the two in the proportion of two eqs. of soda to one of potassa, the same result was obtained as from the latter alone. The following is an outline of Mr. Dale's process. A watery solution of the mixed alkalies is evaporated to the sp. gr. 1·35, and then mixed with saw-dust to the consistence of a paste. This is heated on iron plates to 400° F., and kept at this temperature, with constant stirring, for an hour or two. The mass is now dark-coloured, and contains from 1 to 4 per cent. of oxalic acid, with about 0·5 per cent. of formic acid. The heat is continued and extended till the mass becomes quite dry, care being taken that it is not charred. It now contains from 28 to 30 per cent. of oxalic acid, combined with potassa and soda. By washing the powder on a filter with solution of carbonate of soda, the oxalate of potassa is converted into oxalate of soda, and all traces of potassa are washed out. The oxalate of soda is decomposed by heated milk of lime, and the resulting oxalate of lime by sulphuric acid. The solution of oxalic acid is now evaporated, and yields the acid in crystals. Two pounds of saw-dust afford one of oxalic acid. (See *Am. Journ. of Pharm.*, July, 1863, p. 360.) M. Drechsel has prepared oxalic acid artificially by heating carbonic acid with sodium, diffused in sand, to the temperature of boiling mercury. (*Journ. de Pharm.*, Dec. 1868, p. 460.)

As the oxalic acid of commerce often contains more or less of foreign matter, it requires for certain purposes to be purified. M. E. J. Maumené gives the following process for the purpose, which he says answers better than the method generally recommended. The acid is dissolved in sufficient hot water to give on cooling only from 10 to 20 for 100 of the crystals, according to the degree of impurity. The first crystals are put aside. The mother-water is then concentrated; and, if the resulting crystals be submitted to two or three successive crystallizations, the acid will be obtained quite free from all alkaline oxalate. (*Journ. de Pharm.*, Fev. 1864, p. 154.) Stolba prefers the method of purification by sublimation, especially for analytic purposes. His precise mode of proceeding will be found in Buchner's *Neues Repertorium* (1869, xviii. 182).

Properties. Oxalic acid is a colourless crystallized solid, possessing considerable volatility, and a strong, sour taste. Its crystals have the shape of slender, flattened, four or six-sided prisms, with two-sided summits; and, when exposed to a very dry atmosphere, undergo a slight efflorescence. It sublimes at 180° F., and does not melt till heated to

280° F. (*Guy.*) It dissolves in about nine times its weight of cold, and in its own weight of boiling water. The solution of the crystals takes place with slight crepitation. It dissolves also, but not to the same extent, in alcohol. The presence of nitric acid renders it more soluble in water. It combines with salifiable bases, and forms salts called oxalates. The most interesting of these are the three *oxalates of potassa*, severally called *oxalate*, *binoxalate*, and *quadroxalate*, and the oxalate of lime. The binoxalate and quadroxalate, both popularly called *essential salt of lemons*, are employed for removing iron moulds from linen, and act by their excess of acid, which forms a soluble salt with the sesquioxide of iron constituting the stain. Oxalic acid is used for removing ink stains and iron moulds, for cleaning the leather of boot-tops, and for discharging colours in calico-printing.

This acid has a very strong affinity for lime, and forms with it an insoluble precipitate consisting of oxalate of lime, whenever the acid and earth are brought into contact in solution. It is even capable of decomposing fluoride of calcium, evolving hydrofluoric acid. (*J. W. Slater.*) Oxalic acid and its soluble combinations are the best tests for lime; and, conversely, a soluble salt of lime for oxalic acid. When lime is searched for, oxalate of ammonia forms the most convenient test. So strong is the mutual attraction between this acid and lime, that the former takes the latter even from sulphuric acid. Hence the addition of a soluble oxalate disturbs the transparency of a solution of sulphate of lime.

Oxalic acid is distinguished from all other acids by the form of its crystals, and by its solution yielding a precipitate with lime-water, insoluble in an excess of the acid.

Composition. Oxalic acid consists of two eqs. of carbon 12, and three of oxygen 24 = 36. Some chemists consider it a bibasic acid, and double these numbers. When crystallized, three eqs. of water 27 must be added, making the eq. of the crystals 63. Two eqs. of this water may be driven off by a regulated heat, by which the acid is made to effloresce, but the third cannot be expelled without destroying the acid itself. Accordingly, anhydrous oxalic acid is not known to exist. From the constitution of oxalic acid thus given, it is plain that this acid corresponds in composition with carbonic acid and carbonic oxide taken together. Notwithstanding that it contains less oxygen than carbonic acid, it is incomparably stronger as an acid, owing probably to some peculiarity in the mode in which its elements are combined. The composition of the acid not only corresponds with the united constituents of carbonic acid and oxide, but there is reason to believe that these two compounds are actually its proximate constituents; for, if treated with strong sulphuric acid, the whole of the water will be abstracted, and the elements of the dry oxalic acid are instantly resolved into equal volumes of carbonic acid and carbonic oxide. Oxalic acid, in combining with salifiable bases, sometimes drops its essential equivalent of water, at other times retains it. Thus the oxalate of lead is a compound of the dry acid and protoxide of lead; while the oxalate of lime retains one equivalent of water.

Medical and Toxical Properties. Oxalic acid, in *small* doses, largely diluted with water and sweetened to the taste, forms an agreeable, cooling beverage, which may be used in febrile diseases as a substitute for lemonade. M. Nardo recommends it as an antiphlogistic and anodyne remedy in inflammation of the mucous membranes, given in the dose of a grain and a half dissolved in eight fluidounces of liquid. It has been given in phthisis, with the asserted effect of lessening the night-sweats and expectoration, in the dose of half a grain, three or four times a day, increased to a grain. Combined with binoxalate of potassa it has been used with extraordinary success in scurvy. Notwithstanding the safety of its employment in medicinal doses, it is a virulent poison in larger quantities, producing death with great rapidity and certainty. Instances are on record of its proving fatal in ten minutes, and few survive the effects of a poisonous dose beyond an hour. A case is recorded in the *Chemical News* (April 24, 1868), in which death occurred in a young woman about ten minutes after she had taken three-quarters of an avoirdupois ounce of the poison. As this acid is generally kept in the shops, and not a few instances are on record of its fatal effects when taken by design, or by mistake for Epsom salt, it is necesssry to be somewhat full on its toxical relations.

Oxalic acid was first noticed as a poison by Mr. Royston in 1814; since which time it has been investigated in this relation principally by the late Dr. A. T. Thomson, of London, Dr. Percy, of Lausanne, Dr. Coindet, of Geneva, and Dr. Christison, of Edinburgh. Since its properties of certainty and rapidity as a poison have been more generally known, its employment for committing suicide has become more frequent.

From the general resemblance which the crystallized oxalic acid bears to Epsom salt, many fatal mistakes have occurred in consequence of its being sold for that saline purgative. Nothing, however, can be easier than to distinguish them by tasting a minute portion of the suspected substance, which, if oxalic acid, will be found strongly sour, whereas the salt in question is bitter. Unfortunately, however, in the instances of these fatal mistakes, no suspicions being awakened, the solution is swallowed with haste, and the mischief is done before the victim is aware of his danger.

Oxalic acid acts on the economy in two principal ways, according as its solution is concentrated or dilute. When concentrated it causes exquisite pain, followed by violent efforts to vomit, then sudden dulness, languor, and great debility, and finally death without a struggle. When dissolved in twenty times its weight of water, it possesses no corrosive and hardly any irritating power, and is yet a fatal poison, causing death by acting on the

brain, spinal marrow, and heart. This statement, however, does not accord with the observations of Dr. Letheby, who asserts that the acid, whether in strong or weak solution always exercises a corroding or softening power on the animal tissues.

The morbid appearances caused by oxalic acid are various. In a dissection reported by Dr. Christison, the mucous coat of the throat and gullet had an appearance as if scalded, and that of the gullet could be easily scraped off. The inner coat of the stomach was pultaceous, in many points black, in others red, and that of the intestines, similarly but less violently affected. In another case, the whole villous coat of the stomach was either softened or removed, as well as the inner membrane of the œsophagus; so that the muscular coat was exposed, and this coat exhibited a dark gangrenous appearance, being much thickened and highly injected. The stomach usually contains a dark fluid, resembling coffee-grounds, consisting chiefly of altered blood. Dr. Herbert Barker reports a fatal case of poisoning by this acid, in a boy aged sixteen years, in which about a drachm of the acid had been taken in the solid state. During life the tongue and lips were unusually pale, but not excoriated. The tongue, after death, was found dotted with white spots. (*B. and F. Medico-chir. Rev.*, Am. ed., April, 1856, p. 402.) Dr. Snow, of London, has seen a case, in which, after death, the tongue and lips were very white, while the stomach was black. In a few cases no morbid appearances have been discovered.

In the treatment of poisoning by oxalic acid, the remedial measures must be employed with great promptitude. If the antidotes are not at hand, and vomiting is not free, emetics will be proper. The stomach pump would be useful, but no delay in the application of other remedies is admissible in the expectation of its use. Dr. Christison objects to the use of warm water to facilitate vomiting, from a fear that it would increase the danger by favouring the absorption of the poison; but it may be a question whether this evil, considering the incidental benefit of the water in promoting vomiting, is not less than that of the corrosion of the stomach, which copious dilution has a tendency to prevent. The proper antidote is chalk or magnesia, mixed with water; and as soon as either can be procured, it must be administered in large and repeated doses. These substances act by neutralizing the poison, forming with it an insoluble oxalate of lime or of magnesia, both of which are inert. The soluble salts of oxalic acid, as oxalate of ammonia and oxalate of potassa, are likewise poisonous, and the antidotes for them are the same as for the acid.

The best tests for the detection of oxalic acid in the contents of the stomach, or in the vomited matter, in cases of suspected poisoning by this acid, are chloride of calcium, sulphate of copper, and nitrate of silver. The first causes a white precipitate of oxalate of lime, known by its being soluble in nitric acid; the second, a bluish-white precipitate of oxalate of copper; and the third, a dense white precipitate of oxalate of silver, which, when dried and heated, becomes brown and detonates faintly. When the antidotes have been freely used during life, the poison will be in the state of oxalate either of lime or magnesia. In this case, the oxalate found is to be boiled with a solution of carbonate of potassa, whereby an oxalate of potassa will be generated; and this must then be examined with the reagents above indicated. B.

OXALIS ACETOSELLA. *Wood-sorrel. Acetosella.* The wood-sorrel is a small, perennial, herbaceous, stemless plant, with numerous radical leaves, which are all ternate, and supported upon slender hairy petioles. The leaflets are obcordate, entire, hairy, of a yellowish-green colour, but frequently purplish on their under surface. The scape or flower-stalk, which usually exceeds the petioles in length, is furnished with two scaly bractes near the middle, and terminates in a large white, or flesh-coloured flower, marked with red streaks. The styles are of the same length as the inner stamens. This plant is a native both of Europe and North America. In this country it is found chiefly in the mountainous regions of the interior. It selects shady places, such as woods, groves, and hedges, and flowers in May. Other indigenous species of Oxalis, more widely diffused than *O. Acetosella*, might be substituted for it without disadvantage; as they possess similar properties. They all have ternate leaves with obcordate leaflets, and, with the single exception of *O. violacea*, bear yellow flowers. The whole herbaceous portion may be used.

Wood-sorrel is without smell, and has an agreeable sour taste. It owes its acidity to *binoxalate of potassa*, which is sometimes separated for use, and sold under the name of *salt of sorrel*. This is prepared in Switzerland and Germany, from different species of Oxalis and Rumex, by the following process. The plants, previously bruised, are macerated for some days in water, and then submitted to pressure. The liquid thus obtained is mixed with clay, and occasionally agitated for two days. At the end of this time, the clear liquor is decanted, and evaporated so that crystals may form when it cools. These are purified by solution and a new crystallization. Five hundred parts of the plant afford four parts of the acidulous salt. The same salt may be prepared by exactly neutralizing with potassa one part of oxalic acid in solution, then adding one part more of the acid, and evaporating the solution so that it may crystallize upon cooling. Binoxalate of potassa is in rhomboidal crystals, of a sour, pungent, bitterish taste, soluble in forty parts of cold and six parts of boiling water (*Kane*), and unalterable in the air. It contains 72 parts or two equivalents of oxalic acid, 47·2 parts or one eq. of potassa, and 27 parts or three eqs. of water. *Quadroxalate of potassa* is often substituted for the binoxalate. It is prepared in the same manner except that, instead of one part, three parts of the acid are added to

the original proportion neutralized by potassa. Both salts are kept in the shops under the names of *salt of sorrel* and *essential salt of lemons*, and are employed for removing iron mould and ink stains from linen, and sometimes as a test for lime. Both are poisonous though in a less degree than uncombined oxalic acid.

This and other species of sorrel are refrigerant; and their infusion, or a whey made by boiling them in milk, may be used as a pleasant drink in febrile and inflammatory affections. A solution of the binoxalate of potassa is used, on the continent of Europe, as a substitute for lemonade. It has recently been recommended by W. H. Taylor as extraordinarily efficacious in scurvy, having effected cures in that complaint after lemon-juice had failed. The salt used contained an excess of oxalic acid. It was probably the quadroxalate. Four grains were given three times a day. (*Lancet*, June 5, 1869, p. 777.) The fresh plant, eaten raw, is said to be useful in scurvy. *Oxalis crassicaulis*, a Peruvian species, yields an edible root, and, by expression from its leaves, a very sour and astringent juice, which is employed in the form of syrup, in hemorrhages, chronic catarrh, bowel affections, and gonorrhœa, with asserted advantage. W.

OX-GALL. *Fel Bovinum.* The bile of the ox is a viscid fluid, of a green or greenish-yellow colour, a peculiar nauseous odour, and a bitter taste. The exact composition of bile is not yet settled. According to Berzelius, it contains, 1. *bilin*, 2. *cholepyrrhin*, to which the bile owes its colour, 3. mucus, 4. extractive matters, 5. a peculiar fatty matter, originally found in biliary calculi, called *cholesterin*, 6. oleate, margarate, and stearate of soda, with a little fatty matter not saponified, 7. chloride of sodium, sulphate, phosphate, and lactate of soda, and phosphate of lime. Of these substances, the most abundant and essential is *bilin*. This, when pure, is uncrystallizable, colourless, translucent, inodorous, of an acrid and bitter taste with an after-taste of sweetness, inflammable, soluble in all proportions in water and anhydrous alcohol, insoluble in ether, neither alkaline nor acid, and composed partly of nitrogen. One of its most striking properties is the great facility with which it undergoes decomposition; and hence the numerous principles which different chemists have found in bile, many of which are nothing more than metamorphoses of bilin. Under the action of acids, it is changed into two resinous acids called respectively *fellinic* and *cholinic acid*, and into *taurin* and ammonia. The colouring principle or *cholepyrrhin* is also readily changed, and gives rise to various new products, among which are *bilverdin*, a green colouring matter resulting from the absorption of oxygen, and *bilifulvin*, a yellow colouring matter, which is a double salt of lime and soda with a peculiar azotized acid. (*Journ. de Pharm.*, 3e sér., iii. 177; from the *Journ. für praktische Chemie.*) E. A. Platner succeeded in separating the chief constituent of bile in a crystalline form, and considered it a compound of soda with a peculiar organic body. Liebig denominated this compound *bilate of soda*. Among the most recent and authoritative analyses of bile is that of Strecker, whose views differ essentially from those of Berzelius. According to Strecker, the bile of the ox, independently of the colouring, fatty, and saline matters above mentioned, consists essentially of a mixture of nitrogenous acid free from sulphur, which he calls *cholic acid* (*glycocholic acid*), and an uncrystallizable, sulphuretted acid also containing nitrogen, denominated *choleic acid* (*taurocholic acid*), both of which are combined with soda, constituting a mixture of cholate and choleate of that alkali. These two salts may be separated in the following manner. Dry ox-bile is treated with absolute alcohol, and the tincture precipitated by ether in excess. Both salts are deposited, and the cholate crystallizes upon standing, the choleate remaining in an amorphous form, resembling oily or resinous matter. They may be separated more completely by taking advantage of their different relations to the acetate and subacetate of lead. Both the acids are precipitated by the subacetate, the cholic only by the acetate. If the deposit above referred to be dissolved in water, solution of acetate of lead will throw down a cholate of lead, while the addition of the subacetate of lead to the remainder will precipitate the choleate. The acids may be separated from the salts of lead by sulphuric acid, and then recombined with soda. Both of the acids are decomposed by the alkalies, with the aid of heat, into *cholalic acid*, which contains neither nitrogen nor sulphur, and into another complex body, which, in the case of cholic acid, is a nitrogenous basic substance named *glycocine* (the glycocoll or sugar of gelatin of other chemists), and in that of choleic acid, a neuter substance called *taurine*, which contains both nitrogen and sulphur, the latter in the extraordinary proportion of 24 per cent. Acids with a boiling heat have an analogous effect, though the nature of the acid produced is different, the cholic acid being resolved into *choloidic acid* and glycocine, and the choleic into the same acid and taurine. Hence it has been inferred that the characteristic acids of bile consist of one acid, associated in the cholic with glycocine, and in the choleic with taurine; so that they have now received the more distinctive names of *glycocholic* and *taurocholic acids*, the former nitrogenous, the latter containing nitrogen and additionally two eqs. of sulphur (See Gregory's *Organic Chemistry*, 4th ed., Lond., p. 513; also a paper by Dr. J. C. Dalton in the *Am. Journ of Med. Sci.*, N.S., xxxiv. 305.) Since the examination of bile by Strecker, which ended in these results, further researches have led him to the discovery of other new principles in that part of bile which is soluble both in alcohol and ether. Independent of the fatty matters (glycerides) and cholesterin, he has detected 1. *lecithin*, a substance previously noticed by M. Gobley, which is resolved under the influence of baryta water into fatty acids, and *phosphoglyceric* acid, 2. *sarcolactic* acid, and 3. an energetic base which

calls *cholin*. For the methods of isolating these substances, we must content ourselves with referring to the *Journal de Pharmacie* (Nov. 1861, p. 374). Besides soda, it is said that there are small but variable quantities of potassa and ammonia combined with the glycocholic and taurocholic acids. In relation to the fatty matters of bile, M. Gobley has shown that they consist of olein, margarin, cholesterin, and especially *lecithin*, a fatty principle the characters of which were made known by M. Gobley, and that the oleic and margaric acids, generally supposed to exist in bile combined with soda, are the results of the decomposition of the last-mentioned principle, through the influence of putrefaction or chemical reagents. (*Journ. de Pharm.*, xxx. 246.)

Bile was formerly highly valued as a remedy in numerous complaints, and was considered peculiarly applicable to cases attended with deficient biliary secretion. It is supposed to be tonic and laxative. It is prepared for use by evaporating it to the consistence of an extract. The dose is from five to ten grains. Dr. Bonorden has found the most extraordinary effects, in the resolution of hypertrophies, from bile applied directly to the parts affected. Hypertrophy of the mamma and that of the tonsils are particularly mentioned as yielding with surprising facility to this application; but good may be expected from it in all cases of the affection, in which the part can be reached. He employs a mixture of 3 parts of inspissated bile, 1 part of extract of conium, 2 of soda soap, and 8 of olive oil, to be rubbed on the part four times a day. He has also found advantage in similar affections of the eye as opacity of the cornea, pannus, and staphyloma, from bile dropped into the eye, or applied by a hair-pencil, several times a day. (*Med. Times and Gaz.*, Oct. 1858, p. 353.) *Refined ox-gall*, much used by limners and painters, is prepared, according to Gray, in the following manner. Take of "fresh ox-gall one pint; boil, skim, add one ounce of alum, and keep it on the fire for some time; to another pint, add one ounce of common salt in the same manner; keep them bottled up for three months, then decant off the clear; mix them in an equal proportion; a thick yellow coagulum is immediately formed, leaving the refined gall clear and colourless." A formula is given in the British Pharmacopœia for purifying bile. (See *Fel Bovinum Purificatum*, page 1167.) W.

PÆONIA OFFICINALIS. *Peony.* This well-known plant is a native of Southern Europe, but is everywhere cultivated in gardens for the beauty of its flowers. The root, flowers, and seeds were formerly officinal. The *root* consists of a caudex about as thick as the thumb, which descends several inches into the ground, and sends off in all directions spindle-shaped tubers, which gradually taper into thread-like fibres, by which they hang together. It has a strong, peculiar, disagreeable odour, and a nauseous taste, which is at first sweetish, and afterwards bitter and somewhat acrid. The odour is lost, or much diminished by drying. Peony root was in very great repute among the ancients, who used it both as a charm and as a medicine in numerous complaints, particularly epilepsy. In modern times it has also been given in epilepsy and various nervous affections, but is at present seldom used. Dr. A. Livezey, of Lumberville, Penn., states that it is much used in the convulsions of children in his neighbourhood, and bears testimony to its possession of decided nervine powers. (*Bost. Med. and Surg. Journ.*, lv. 467.) The dose of the fresh root is from two drachms to an ounce, boiled in a pint of water down to half a pint, which should be taken daily. It is said to be less active when dried. The expressed juice of the recent root is recommended in the dose of an ounce. It is milky, of a strong odour, and very disagreeable taste. The *flowers* are usually deep-red, though in some varieties light-red, and even whitish. They have, when fresh, an odour similar to that of the root, but feebler, and an astringent, sweetish, herbaceous taste. When dry they are inodorous. As a medicine they have little power. The *seeds* are roundish-oval, about as large as a pea, externally smooth, shining, and nearly black, internally whitish, inodorous when dry, and of a mild, oleaginous taste. By some authors they are said to be emetic and purgative, by others antispasmodic. They may be given in the same dose with the root, but are not used in regular practice. W.

PALM OIL. This highly valuable fixed oil is the product of *Elais Guiniensis*, a palm growing on the western coast of Africa, and cultivated in the West Indies and South America. It is among the handsomest trees of its graceful family which flourish in the tropical regions of Africa. The oil is obtained by expression from the fruit. It is brought to this country chiefly from Liberia and other places on the African coast, though prepared also in the West Indies, Cayenne, and Brazil. It is not improbable that various species of palms contribute to the supply of this article of commerce.

Palm oil has the consistence of butter, a rich, orange-yellow colour, a sweetish taste, and an agreeable odour, compared by some to that of violets, by others to that of the Florentine orris. By age and exposure it becomes rancid and of a whitish colour. It melts with the heat of the hand, and when perfectly fluid passes readily through blotting-paper. Highly rectified alcohol dissolves it at common temperatures, and in ether it is soluble in all proportions. According to M. Henry, it consists of 31 parts of stearin and 69 of olein. But, from the experiments of Frémy and Stenhouse, it appears that the stearin has peculiar properties entitling it to be considered as a distinct principle; and it has accordingly received the name of *palmitin*. This is converted into *palmitic acid* by saponification. (*Kane's Chemistry.*) It appears also that a considerable proportion of this acid, together with some glycerin, exists uncombined in the oil, as ascertained by MM. Pelouze and Boudet; so that the changes which are effected in oils, through the

agency of alkalies, in the process of saponification, take place, to a certain extent, spontaneously in palm oil. (*Journ. de Pharm.*, xxiv. 389.) Hence it is more easily saponified than any other fixed oil. Preparatory to saponification, it may be bleached rapidly, according to J. J. Pohl, by heating it quickly to 464° F., and keeping it for ten minutes at that temperature. It loses for a time its peculiar odour by the process, acquiring an empyreumatic smell; but this after a while ceases to be perceived, and the characteristic odour returns. (See *Am. Journ. of Pharm.*, xxvii. 346.) Englehart bleaches it in the following manner. One thousand pounds of the oil are heated in a boiler to 144° F., and kept at that temperature until the next day, when it is decanted into a clean vessel, and cooled to a point between 98° and 104° F. In another vessel 15 lbs. of bichromate of potassa are dissolved in 45 lbs. of boiling water; and, when the solution is partially cooled, 60 lbs. of muriatic acid are added. This solution is then mixed with the oil, and briskly agitated. In five minutes the colour changes to green, through the reduction of the chromic acid; and, with a continuation of the agitation, the oxide of chrome separates, and nothing more is necessary than washing with water to get the oil colourless. (*Am. Journ. of Pharm.*, July, 1868, p. 333.) Palm oil is said to be frequently imitated by a mixture of lard and suet, coloured with turmeric, and scented with Florentine orris. It is much employed in the manufacture of a toilet soap, which retains its pleasant odour. Palm oil is emollient, and has sometimes been employed in friction or embrocation, though not superior for this purpose to many other oleaginous substances. W.

PANCREATIC EMULSION. As it is generally admitted that, among the offices of the pancreatic juice, is that of emulsionizing fatty matters that may pass through the stomach undigested, so as to facilitate their absorption, it would appear highly probable that this secretion might prove useful in cases in which fats are digested with difficulty if at all. Dr. Horace Dobell, physician to the "Royal Infirmary for Diseases of the Chest," having noticed that consumptive patients are very apt to have a dislike for fat, and thinking that this dislike might result from an inability to digest this kind of food, reasonably inferred that the pancreatic secretion might prove useful in these cases by supplying the wanted power. He was, therefore, induced to treat a series of consumptive cases of this kind with the pancreatic juice of the pig, which he gave in the form of emulsion with the fat of beef, stirred in milk. His expectations were confirmed by the results. The great majority of cases were improved by the remedy, which he now confidently recommends. The preparations which he prefers are pancreatic emulsions of cod-liver and lard oils. In this connection, the pancreatic juice remains sound for a long time; though, unmixed with fat, the juice speedily undergoes decomposition. The emulsion with cod-liver oil, as prepared by Messrs. Savory and Moore, of London, has the appearance of a white paste, and the consistence of thick clotted cream. The dose is from one to three teaspoonfuls, once or twice daily, in a cup of milk, to which a little brandy may be added. (See *Am. Journ. of Pharm.*, March, 1866, p. 143; from *The Chemist and Druggist*, Jan. 15, 1866.)

The name of *pancreatine* has been conferred on the pancreatic juice itself, which was brought to the notice of medical men, by Dr. G. Harley, so early as 1858, "as uniting in itself the properties of all the digestive fluids." But Dr. Dobell appears to have first carried the idea into effect; though it was not till September, 1864, that his communication was published in the *Lancet*. It has been suggested that, if the juice really acts beneficially in aiding the digestion of the fatty ingredients of food, it would be best to administer it, not previously mixed with fat which probably neutralizes it; perhaps in spirit, which dissolves it readily. (*Pharm. Journ.*, Feb. 1, 1866, p. 405.) W.

PARIETARIA OFFICINALIS. *Wall Pellitory.* A perennial European herb, growing on old walls and heaps of rubbish. It is inodorous, has an herbaceous, somewhat rough and saline taste, and contains nitre derived from the walls where it flourishes. It is diuretic and refrigerant, and is said also, but without good reason, to be demulcent and emollient. The ancients employed it in various complaints, and it is still considerably used on the continent of Europe, especially in domestic practice. It is given in complaints of the urinary passages, dropsy, and febrile affections, usually in the form of decoction. The expressed juice is also used, and the fresh plant is applied in the shape of a cataplasm to painful tumours. W.

PARTHENIUM INTEGRIFOLIUM. *Prairie Dock.* This is an herbaceous perennial, growing abundantly in the prairies of our South-western States. It is recommended by Dr. Mason Houlton as a powerful antiperiodic. The flowering tops are the part used. They have an intensely bitter taste; and two ounces of them in the dried state, given in the form of infusion, are thought by Dr. Houlton to be equivalent to twenty grains of sulphate of quinia. Thirty successive cases of periodic fever were cured by this remedy, without any unpleasant effect on the nervous system. (*Med. Exam.*, N.S., ix. 719, from *Memphis Med. Recorder*; and *Pharm. Journ.*, xii. 602, from *N.Y. Journ. of Pharm.*) W.

PATENT YELLOW. *Mineral Yellow.* A pigment, consisting of chloride combined with protoxide of lead. It is prepared by mixing common salt and litharge with a sufficient quantity of water, allowing the mixture to stand for some time, then washing out the liberated soda, and exposing the white residue to heat. W.

PAULLINIA. *Guarana.* This is a new medicine introduced into Europe from Brazil, which has attracted some attention from the asserted fact, that it contains a principle identical with caffein. The name of *paullinia* has been bestowed upon it from the generic title of the plant from which it is obtained. That of *guarana*, by which it was previously known, was derived from a tribe of aborigines, called Guaranis, who are said to use it extensively as a corrigent of their vegetable diet. It is prepared from the seeds of the *Paullinia sorbilis* of Martius, a climbing shrub, belonging to the class and order Octandria Trigynia of the Linnæan system, and the natural family of the Sapindaceæ. Another species, the *P. Cupana*, growing on the banks of the Orinoco River, is said also to yield it. (*Ann. de Thérap.*, 1858, p. 70.) The seeds, which are contained in a three-celled, three-valved, coriaceous capsule, are lenticular and almost thorny, and invested with a flesh-coloured arillus, which is easily separable when dry. They are prepared by powdering them in a mortar, or upon a chocolate stone previously heated, mixing the powder with a little water, exposing it for some time to the dew, then kneading it into a paste, mixing with this some of the seeds either whole or merely bruised, and finally forming the mixture into cylindrical or globular masses, which are dried and hardened in the sun, or by the smoke of a fire. These masses are of a reddish-brown colour, rugose on the surface, very hard, and of a marbled appearance when broken. Paullinia is of a somewhat astringent and bitterish taste, and, in this as well as in its odour, bears some resemblance to chocolate, though not oleaginous. It swells up and softens in water, which partially dissolves it. Martius found in it a crystallizable principle, which he named *guaranin*, but which has been proved by MM. Berthemot and Dechastelus to be identical with *caffein*. The discovery of caffein in four plants belonging to distinct natural families, namely, the coffee and tea plants, the Paraguay tea, and the Paullinia, is a highly interesting result of recent chemical investigations. It is said to be more abundant in the Paullinia than in either of the other vegetables; 5·07 per cent. having been found by Dr. Stenhouse in Paullinia, while he got only 2·13 from good black tea, 1·00 per cent. from coffee, and 1·2 from Paraguay tea. (*Pharm. Journ.*, xvi. 213.) According to Berthemot and Dechastelus, it exists in the seeds united with tannic acid, with which it appears to form two compounds, one crystallizable and soluble in water, the other of a resinoid appearance and insoluble. Besides these ingredients, the seeds contain free tannic acid, gum, albumen, starch, and a greenish fixed oil. (*Journ. de Pharm.*, xxvi. 514.) More recently M. Fournier has found in paullinia, besides tannate of caffein, the following principles; gum, starch, an acrid green fixed oil, a concrete volatile oil, an aromatic liquid volatile oil soluble in water with a little alcohol, another liquid volatile oil scarcely soluble in water, a peculiar principle not precisely determined, and tannic acid. (*Ibid.*, Avril, 1861, p. 291.)

It is said to have been by mistake that *paullinia* and *guarana* have been considered identical; the former term being applicable exclusively to the product of the two species of Paullinia above referred to, while the latter belongs properly to a preparation made by the aborigines, which, though it contains the seeds of the Paullinia, is a mixture of various substances, among them chocolate and farina, but the precise composition of which is most carefully kept secret by the natives. (*Ann. de Thérap.*, 1858, p. 70.)

The effects of paullinia upon the system are said to be those of a tonic; but they do not appear to have been very accurately investigated. It is highly probable, both from its composition and the use made of it by the natives of Brazil, that it has an influence over the nervous system similar to that of tea and coffee. It is habitually employed by the Indians, either mixed with articles of diet, as with cassava or chocolate, or in the form of drink, prepared by scraping it, and suspending the powder in sweetened water. It is considered by them useful in the prevention and cure of bowel complaints. Dr. Gavrelle, who was formerly physician to Don Pedro, in Brazil, and there became acquainted with the virtues of this medicine, called the attention of the profession to it some years since in France. He had found it advantageous in the diarrhœa of phthisis, sick-headache, paralysis, tedious convalescence, and generally as a tonic. By Dr. Ritchie, Surgeon in the British navy, it is highly recommended in irritation of the urinary passages. (*Ed. Month. Journ. of Med. Sci.*, N. S., v. 467.) Dr. Hervé has been in the habit of using it daily for five or six years, and has never failed to derive advantage from it in idiopathic diarrhœa, even in the most obstinate cases. (*B. and F. Med.-chir. Rev.*, Jan. 1858, p. 192.) It may be given in substance, in the quantity of one or two drachms, scraped into powder and mixed with sweetened water; but the most convenient form of administration is that of spirituous extract. According to M. Dechastelus, alcohol is the only agent which completely extracts its virtues; ether and water effecting this object but partially. Of the extract eight or ten grains may be given during the day in the form of pill. Paullinia may also be taken along with chocolate as a drink. W.

PEACH LEAVES. *Leaves of Amygdalus Persica.* (Willd. *Sp. Plant.* ii. 982.) *Persica vulgaris.* (Miller, Lamarck.) Every one is familiar with the appearance of the common peach-tree. It is characterized specifically by having "all the serratures of the leaves acute, and by its sessile solitary flowers." Though its native country is not certainly known, it is generally supposed to have been brought originally from Persia. In no country, perhaps, does it attain greater perfection, as regards the character of its fruit, than in the United States. Peaches are among the most grateful and wholesome of our

summer fruits. They abound in saccharine matter, which renders their juice susceptible of the vinous fermentation, and a distilled liquor prepared from them has been much used, in some parts of the country, under the name of *peach brandy*. The kernels of the fruit bear a close resemblance in appearance and properties, and probably in chemical nature, to bitter almonds, for which they are frequently, and without inconvenience, substituted in our shops. They are employed by distillers in the preparation of *liqueurs*, and by cake-bakers to give flavour to various productions of their ovens; and are said to yield as much amygdalin as bitter almonds. The flowers, leaves, and bark also have the peculiar odour and taste of bitter almonds, and yield hydrocyanic acid. The leaves afford a volatile oil by distillation. The distilled water prepared from them was found, in one instance, to contain 1·407 parts of hydrocyanic acid in 1000, and in another only 0·437 parts in the same quantity. From some experiments it is inferred that the proportion of acid is greatest where there is least fruit. (*Am. Journ. of Pharm.*, xxiv. 172.)

Medical Properties. Peach leaves are said to be laxative; and they probably exert, to a moderate extent, a sedative influence over the nervous system. They have been used as an anthelmintic with great reported success. More recently their infusion has been recommended in irritability of the bladder, in sick stomach, and hooping-cough. Half an ounce of the dried leaves may be infused in a pint of boiling water, and half a fluidounce given for a dose three times a day, or more frequently. Dr. Dougos gives, in hooping-cough, a pint of the strong infusion, in small doses, in the course of the day. (*Journ. de Pharm.*, xxiii. 356.) The flowers are also laxative; and a syrup prepared from them is considerably used, in infantile cases, upon the continent of Europe. Woodville states that a drachm of the dried flowers, or half an ounce in their recent state, given in infusion, is the dose as a vermifuge. Cases of fatal poisoning from their use in children are on record. The kernels have more of the peculiar powers of hydrocyanic acid, and therefore require to be used with some caution. Blanched, and rubbed up with hot water, they form an emulsion well adapted to coughs depending on or associated with nervous irritation. The bruised leaves, flowers, or kernels may be used by the apothecary for cleansing his vessels from disagreeable odours. The dried fruit, stewed with sugar, is an excellent laxative article of diet, suitable to cases of convalescence attended with torpid bowels. W.

PEARL WHITE. *Pearl Powder.* This is identical with the subnitrate of bismuth, described at *page* 1064, and is made by adding a solution of the ternitrate of teroxide of bismuth to distilled water. It is used as a cosmetic. B.

PELARGONIUM ODORATISSIMUM. *Rose Geranium.* This well-known plant, so much a favourite for its odour in our dwellings and conservatories, is a native of the Cape of Good Hope, but is said to be cultivated extensively in the South of France and in Turkey for the sake of its volatile oil, which is much employed for the adulteration of the oil of roses. According to Guibourt, three species of Pelargonium yield a volatile oil by distillation, closely analogous in smell to that of the rose; the species above named, *P. capitatum* and *P. roseum*. (*Hist. Nat. des Drogues*, 4e ed., iii. 52.) The oil is obtained from the leaves M. Recluz obtained from 35 ounces of *P. odoratissimum* two drachms of a volatile, crystallizable oil. (Mérat et De Lens, *Dict. de Mat. Méd.*, iii. 368.) According to Septimus Piesse, 1 cwt. yields about two ounces. (See *Am. Journ. of Pharm.*, xxvi. 368.) As we have seen the oil in our shops, purporting to be the oil of P. odoratissimum, it is perfectly fluid at ordinary temperatures, of a pale brownish-yellow colour, and the characteristic smell of the plant, recalling merely that of the rose. Gregory states that pelargonic acid was first obtained from the oil of *P. roseum*, which is probably the same as that under consideration. (*Organic Chem.*, 4th ed., Lond., p. 274.) This oil is now much used in perfumery, and, dissolved in alcohol in the proportion of three ounces to the gallon, forms the preparation called "*extract of rose-leaf geranium.*" Mr. Piesse states that, as this oil is used to adulterate that of roses, so is it in its turn adulterated with the cheaper oil of *Andropagon nardus*, cultivated in the Moluccas. (*Am. Journ. of Pharm.*, xxvi. 368.) W.

PERCHLORATE OF POTASSA. This salt has been examined, with a view to its remedial character, by M. Robuteau, whose memoir on the subject was published in the *Gazette Hebdomadaire* (Nov. 6, 1868). The following are his conclusions. 1. Introduced into the system in the quantity of five grammes (77 grains), it is eliminated in 36 or 48 hours, without having undergone any change of composition. Its effects are wholly different from those of the chlorate of potassa. 2. It appears to be useful in intermittents, and, if it prove in fact to have antiperiodic powers, it will be preferable to quinia in pernicious fever from the rapidity of its action. 3. Arsenic diminishes the urea discharged much more than has been supposed; neither sulphate of quinia nor perchlorate of potassa has this effect unless long administered. 4. From the properties it possesses, M. Robuteau thinks it applicable to all diseases in which quinia and nitre are used in reference to their sedative or diuretic properties. (*Ann. de Thérap.*, 1869, p. 141.) W.

PEROXIDE OF HYDROGEN. This substance, though long known to chemists, has but recently been brought into notice as a remedy. It consists of water in which, by the presenting to it of oxygen in a nascent state, an additional equivalent of this element has combined with the hydrogen forming the deutoxide (HO_2). It was discovered by Thenard in 1818. To prepare it, peroxide of barium is rubbed with distilled water so as to form a

liquid paste, which is added gradually, with constant stirring, to distilled water acidulated with one-third of its weight of muriatic acid, contained in a vessel immersed in a freezing mixture. The peroxide of barium (BaO_2) gives up one of its eqs. of oxygen to one eq. of the water (HO), forming an eq. of deutoxide or peroxide of hydrogen (HO_2); while the protoxide of barium left reacts with an eq. of muriatic acid to form one eq. of chloride of barium and one of water. When the muriatic acid is saturated, a fresh quantity of the acid in a concentrated state is added, and then more of the peroxide of barium; and the operation is repeated till the solution will hold no more chloride of barium. It is then immersed in a mixture of ice and salt, and the greater part of the chloride of barium is deposited. The portion remaining in solution may be got rid of by the cautious addition of sulphate of silver, which precipitates sulphate of baryta and chloride of silver. The liquid being now filtered, is concentrated by exposing it in vacuo in a shallow vessel placed over another containing sulphuric acid. The water rises in vapour which is absorbed by the acid, and at last the peroxide of hydrogen is left nearly pure. (*Regnault.*) Thus procured it is a colourless liquid of a fluid consistence, of the sp. gr. 1·452, remaining liquid at zero, beginning to give out oxygen when heated above 60°, and at a higher heat rapidly and sometimes explosively resolved into water and oxygen. But when diluted with water, with which it unites in all proportions, it is not decomposed under 100°. The great facility with which it parts with oxygen renders it a powerful oxidizer; and the simple contact with various substances, as platinum, gold, and silver, causes it to be resolved into oxygen and water. On the contrary, certain other substances, even though ordinarily evincing a strong affinity for oxygen, as phosphorus, for example, are unaffected by it, and there is a large number of bodies, as ammonia, hydrocyanic acid, tobacco, aconite, and most other narcotic substances, which have the property not only of being unaffected by it, but of restraining its oxidizing influence on other bodies. Its relations to ozone are peculiar; and at one time it was conjectured that ozone was nothing else than peroxide of hydrogen. At present the oxygen in it is considered by some as in the positive state and called *antozone*, while *ozone* itself is oxygen in the negative state, and the two mixing produce oxygen in its ordinary state or neutral oxygen. When this neutral condition of oxygen is disturbed, giving rise to the phenomena of ozone, antozone is also liberated. Hence, according to Schönbein, whenever, upon the contact of phosphorus with water, ozone appears, the water is found to contain peroxide of hydrogen. These facts may at some future time prove to have an important bearing on peroxide of oxygen as a physiological or remedial agent; but at present they may be left out of view in treating of it medicinally. It has been detected by M. Struvé, of St. Petersburg, in minute proportion, in the air of the atmosphere in Southern Russia. (*Chem. News*, July 2, 1869, p. 23.) Schönbein has made the same discovery in the vicinity of Basel, in Switzerland. In both instances it was found in the rain-water. (*Neues Repertorium*, 1869, xviii. 364.)

The profession is indebted to Dr. B. W. Richardson, of London, for most of what is known of the physiological operation and therapeutical effects of peroxide of hydrogen. In relation to its influence on organic bodies, Dr. Richardson found that to venous blood, deprived of its fibrin, it imparts oxygen, with an increase of heat, and a change of the colour to red. Fibrin and cellular tissue cause it to evolve oxygen. Sugar and starch are decomposed by it, giving out carbonic acid. Albumen, gelatin, urea, and cutaneous tissue have no effect on it. Injected into the left cavities of the heart of an animal, it restores the irritability of that organ, but has an opposite effect in the right cavities. Thrown into the arteries, immediately after death, it restores for a time the contractile power of the muscles, and suspends cadaveric rigidity, while it counteracts the influence of various medicinal substances that cause muscular spasm. Dr. Richardson inferred from his experiments that the peroxide might be found useful as an antidote to the narcotic poisons, as a local application to gangrenous ulcers, and as an internal remedy in low forms of fever. Subsequently, from numerous therapeutical trials of the remedy, he came to the conclusion, that it is of great value in chronic and subacute rheumatism: acts in the removal of scrofulous tumours like iodine; relieves the paroxysms of hooping-cough, and cuts short the disease more effectually than any other medicine; affords great relief in chronic bronchitis with dyspnœa; and, in phthisis, operates favourably in the early stage by improving digestion and giving increased activity to chalybeate remedies, while, in the advanced stages, it afforded great relief to the dyspnœa and oppression, acting, indeed, in this respect, like opium, without its narcotic effects. In general, it seemed to him to improve digestion, and therefore to be useful in cases complicated with dyspepsia. Sometimes, when freely employed, it produced profuse salivation, suggesting the idea that it might in other respects resemble mercury, and possibly be found capable of replacing this remedy to a certain extent in the treatment of disease. Dr. Richardson recommends that a solution of the peroxide should be used charged with ten volumes of oxygen, the dose of which may be from one to four fluidrachms, freely diluted with water. There are so many substances which decompose the peroxide, that, as a general rule, it is best given without addition; at least nothing should be allowed to remain long in contact with it. There can be no difficulty in obtaining the desired strength of ten volumes of oxygen to one of the solution, by estimating the quantity of oxygen contained in the peroxide of barium employed in the process. (See *Lancet*, Oct. 20, 1860, and April 12, 1862.)

Ozonic ether is a name proposed for a solution of peroxide of hydrogen in ether, which was first noticed by Dr. Richardson. Ether will take a portion of the peroxide from its watery solution, forming a compound of considerable stability, as it has borne a voyage to Australia without change. Dr. Richardson recommends it for diffusion in the state of spray in the sick chamber, as it has great purifying power. Care, however, must be taken to guard against the consequences of its extreme inflammability. (See *Am. Journ. of Pharm.*, March, 1869, p. 156.) But ozonic ether owes the reputation into which it has so suddenly risen to its supposed efficacy in the treatment of diabetes. In a letter by Dr. John Day, dated in Australia, August, 1867, and published in the *Lancet* (Jan. 11, 1868), an account is given of an apparently quite desperate case of that disease, in which he was induced to give the ethereal solution of the peroxide of hydrogen, by the hope of oxidizing the sugar in the circulation, and thus causing its elimination through the lungs instead of the kidneys. He gave half a drachm of the solution, mixed with an ounce of distilled water, three times a day. The effect was most striking. The quantity of urine discharged rapidly decreased to the normal standard, its sp. gr. diminished at the same time, the thirst disappeared, and the patient, who was a woman, appeared to have been snatched from the brink of the grave. In less than a month, she had so far improved that she considered herself quite well, though there was probably still sugar in the urine. The case of a man was afterwards described, in a letter from Mr. S. J. Bayfield, of London, to the *Med. Times and Gaz.* (Oct. 17, 1868, p. 404), in which a cure was effected under the use of the medicine as employed in the case of Dr. Day. Experience thus far would seem to be greatly in favour of the remedy; but, among the first therapeutic experiments of Dr. Richardson with peroxide of hydrogen, had been its use in diabetes; in which, though it appeared to have considerable effect in diminishing the discharge of urine and the secretion of sugar, it had shown no power of arresting the course of the disease, which, so far as traced to its results, had proved uniformly fatal. (*Med. Times and Gaz.*, Dec. 1868, p. 662.) It is yet too soon to determine whether a better fortune awaits the remedy in this mode of exhibition.

Locally employed, peroxide of hydrogen sometimes acts very beneficially, especially in feeble, flabby, or ill-conditioned ulcers, in chancre and diphtheric sores, in all of which it operates, not as a corrosive substance, but probably by imparting oxygen to the diseased tissues, and thus destroying them. W.

PESSARIES, MEDICATED. Pessaries, which are bodies of various magnitude, intended for introduction into the vagina, for the support of the uterus, and other purposes, and were long confined, so far as concerns their preparation, to the domain of the surgical instrument maker, have recently been brought, by Sir J. Y. Simpson, of Edinburgh, within that of the pharmaceutist also. Sir James conceived the idea of making remedial impressions upon the vagina and uterus by the introduction of medicated pessaries, in the same way as suppositories are often introduced into the rectum, with the view of favourably influencing the condition of the neighbouring parts and of the system. For this purpose, some soft material, as cacao butter, with or without a little wax, impregnated with the medicine to be exhibited, is formed into a suitable shape, in the same manner as suppositories, for an account of which the reader is referred to the heading of Suppositoria in the second part of this work. These preparations have now come into extensive use. Prof. Simpson prefers those of a conical shape, almost precisely like that of a Minié bullet. Instead of being rubbed up with the material of the pessary, the medicine may sometimes be introduced into a cavity in its centre, as, for example, a few drops of chloroform liniment. The following is a list of medicines, with their doses, which may be administered in the mode above indicated.

Acetate of lead	7½ grs.	Borax	15 grs.	Morphia	½ grs.
Acetate of lead.....5 Opium 2	7 "	Bromide of potassium	10 "	Opium	2 "
Alum	15 "	Carbonate of soda.....	15 "	Perchloride of iron...	5 "
Alum..... Catechu....	each..... 15 "	Gallic acid	10 "	Persulphate of iron...	5 "
Alum..... Iron	each..... 10 "	Iodide of lead.....	5 "	Sulphate of iron, dried.....	10 "
Atropia	⅟₆ "	Iodide of lead.. 5 Atropia..... ⅟₆	5⅟₆ "	Sulphate of zinc, dried, as caustic	10 "
Bismuth, oxide of.....	15 "	Iodide of potassium...	10 "	Tannin	10 "
		Matico	10 "	Zinc, oxide of	15 "
		Mercurial ointment...	30 "		

(*Ed. Med. Journ.*, May, 1865, p. 1042.) W.

PETROLEUM. *Rock Oil.* This was recognised by the late London and Edinburgh Colleges, but has been omitted in the British Pharmacopœia, and, as it holds no place in that of the United States, takes rank among the extra-officinal medicines. Petroleum belongs to the class of native inflammable substances, called *bitumens*. These are liquids or readily fusible solids, which emit, when heated, a peculiar smell, burn easily, and leave a very small carbonaceous residue. They exist in nature either isolated, or combined with carbon in various proportions, forming the different kinds of bituminous coal. Formerly the lighter coloured, purer, and more liquid forms of petroleum were distinguished by the name of *naphtha*, which was defined to be a transparent, yellowish-white, very light and

inflammable, limpid liquid, of the bituminous character; but as this name has been conferred of late upon the lighter liquid resulting from the distillation of coal tar or petroleum at a comparatively low temperature, and as there is no sufficient line of distinction between the native naphtha and the impure forms of rock oil, it is, we think, desirable that the name should be confined to the artificial product, while the term petroleum is considered as embracing all the native liquid substances belonging to this class. When the bitumen is in the solid state it is called *asphaltum*. This is black, dry, friable, and soluble in water or alcohol. Not unfrequently asphaltum exists in nature mixed with more or less of the liquid substance; and this semi-solid mixture is distinguished by the name of *maltha* or *mineral tar*. Exposed to the air, petroleum gradually passes into the state of asphaltum.

Petroleum has been known from the earliest historical period. Herodotus refers to wells of it existing in Zante, and from time immemorial it has been known in Persia, where it was probaby connected with the origin and ceremonies of fire-worship. Till recently the best-known sources of it were the borders of the Caspian Sea in Persia, at Amiano in Italy, at Gabian in France, the island of Trinidad in the West Indies, and in the Burman Empire near Rangoon, where vast quantities have been annually raised for many centuries, without any apparent exhaustion of the wells from which it was drawn. Within the limits of the United States it has long been known to exist in a few localities. On the borders of Seneca Lake in the State of New York, small quantities of it were collected, and to some extent used in medicine under the name of Seneca oil. In Western Pennsylvania, on Duck Creek in Ohio, near Scottsville in Kentucky, and on the Kenhawa in Virginia, it attracted local attention; and a certain locality in Western Canada had acquired some notoriety by its burning spring. But little attention was paid to it until about twelve years since; when, the preparation of oil for burning, distilled from coal tar, having proved very profitable, and a strong resemblance if not identity having been proved to exist between this and petroleum, enterprise was directed towards some of the known sources of the latter liquid, which was greatly stimulated by success, and soon led to further and astonishing discoveries. Hitherto the most productive locality of rock oil has been in Western Pennsylvania; but it has been found to exist in great quantities elsewhere, and in fact occupies large portions of a region commencing in Western Canada, and extending, through New York and Pennsylvania, westward into Ohio and Kentucky, and far southward into Western Virginia. From later accounts it appears that petroleum exists also abundantly in California, and promises to vie with gold as a source of wealth to that country. Establishments for purifying the petroleum have multiplied with great rapidity, and the quantity of oil collected, and either exported or consumed at home, would be incredible, considering the short time since the trade in it may be said to have begun, were it not attested by positive returns. The quantity of petroleum exported, either crude or refined, independently of that consumed in this country, from the ports of Boston, New York, Philadelphia, and Baltimore, amounted in 1862 to 10,887,701 gallons; in 1863, to 28,250,721; and in 1864, to 31,772,972. (*N. Y. Times*, Feb. 16, 1865.) A copious source of petroleum has recently been developed in the Caucasus; a single boring, 276 feet deep, near Kuaaco, having yielded 1500 barrels daily for a month. (*Pharm. Journ.*, March, 1868, p. 443.)

Petroleum sometimes exists in overflowing springs, as in Canada, N. W. Virginia, and very largely in California, issuing along with the water, and spreading itself over the surface of streams for a considerable distance. It is, however, much more abundantly obtained by digging or boring wells. In this case, if the point struck be below some underground reservoir of the oil, it may rise, as in artesian wells, to the surface. Sometimes it is driven up with considerable though variable force, probably by the expansive power of compressed gas, which not unfrequently escapes along with the oil, and in some places so copiously and steadily as to be used for lighting purposes in the immediate vicinity; the gas being some form of carburetted hydrogen. But in most instances it is necessary to raise the oil by pumps. The distance at which it is found beneath the surface is very different, the depth of boring in Western Pennsylvania varying from 71 to 600 feet. (D. Murray, *Trans. Albany Instit.*, iv. 149.) It is necessary to bore through an overlying rock before reaching it. The oil is generally collected in the fissures and pores of some spongy rock, as sandstone or shale. Its original source was probably an underground distillation of vegetable matter, carried on upon a vast scale by nature, by means of subterranean heat. Its close resemblance to the tar resulting from destructive distillation of organic matter can be explained only upon this supposition.

Crude petroleum is variable in character, being sometimes transparent and of an amber colour, but more generally brown or almost black and opaque in mass, or of various shades between the two, in some instances very thin and mobile, in others thicker, and occasionally almost semi-solid, of a peculiar characteristic odour, always lighter than water, and in great measure volatilizable by heat. A specimen of *Pennsylvania petroleum*, fresh from the wells, was found by Mr. E. S. Wayne, of Cincinnati, to have the sp. gr. 0·815, which, however, after the petroleum had been exposed to the air for 24 hours, rose to 0·825. When subjected to fractional distillation, it yielded liquid products varying in sp. gr. from 0·668 to 0·825; the lightest coming over first. The paraffin from this petroleum Mr. Wayne believes to be very different from that obtained from coal tar, having both a lower boiling

point and lower sp. gr., and, besides, differing in chemical constitution. (*The Druggist*, Cincinnati, June 15, 1860.) In the purer form of naphtha, petroleum is a carbohydrogen, and, on account of the absence of oxygen, has been used for the preservation of potassium. The crude oil consists of a large number of distinct substances, generally carbohydrogens, of various sp. gr. and boiling points, which may be separated by distillation, and by the action of sulphuric acid and soda or potassa. Mr. Schorlemmer states, as the result of his examination of refined American petroleum, the product of the first rectification, that it contains benzol and toluol in small proportion, but consists mainly of hydrides (hydrurets) of the alcohol radicals, of which he isolated four; namely, *hydride of amyl*, $C_{10}H_{12}$, boiling at 92° F.; *hydride of hexyl*, $C_{12}H_{14}$, boiling at 154° F.; *hydride of heptyl*, $C_{14}H_{16}$, boiling at 208° F.; and *hydride of octyl*, $C_{16}H_{18}$, boiling at 236°. (*Chem. News*, April 4, 1863, p. 157.) MM. Pelouze and Cahors have isolated seven distinct carbohydrogens from rectified American petroleum, of a lower boiling point than 392° F.; viz., *butyl hydride* C_8H_{10}, *amyl hydride* $C_{10}H_{12}$, *caproyl hydride* $C_{12}H_{14}$, *œnanthyl hydride* $C_{14}H_{16}$, *capryl hydride* $C_{16}H_{18}$, *pelargonyl hydride* $C_{18}H_{20}$, and *rutyl hydride* $C_{20}H_{22}$. (*Ibid.*, April 25, 1863, p. 197.) W.

Barbadoes petroleum is a black, nearly opaque, inflammable liquid, of the consistence of molasses, unctuous to the touch, and possessing a bituminous taste, and strong and tenacious odour. Its sp. gr. varies from 0·730 to 0 878. When subjected to distillation it yields naphtha, and leaves a solid residue of asphaltum. It is little affected by alcohol, acids, or alkalies, but dissolves in ether and in the fixed and volatile oils. It consists chiefly of carbon and hydrogen, associated with a little nitrogen and oxygen. *Rangoon petroleum*, also called *Rangoon tar* and *Burmese naphtha*, has a greenish-brown colour, a peculiar, rather fragrant odour, and the consistence of goose-fat. It is lighter than water. Heated to 90° it becomes a very mobile liquid. By distilling it in a current of steam, first at 212°, and afterwards super-heated, Drs. W. De la Rue and H. Müller obtained 96 per cent. of volatile products, solid and liquid. The solid product (*paraffin*) amounted to from 10 to 11 per cent., and was found resolvable by these chemists, by fractional crystallization from hot alcohol, into at least two polymeric carbohydrogens, having the probable formula C_nH_n. The liquid product, usually called naphtha, is separable by sulphuric and nitric acids into two sets of carbohydrogens; one set removable by these acids, the other resisting their action. The former set contain fewer eqs. of hydrogen than of carbon, and embrace, among other carbohydrogens, benzol and toluol. The latter, which form by far the larger portion of the liquid product, are perfectly colourless, almost inodorous, very mobile liquids, not congealable by intense cold. Their probable formula, according to Drs. De la Rue and Müller, is C_nH_{n+1}. (See *Chem. Gaz.*, Oct. 1, 1856, p. 375.) B.

The method of purifying petroleum is very nearly the same as that already described for purifying coal tar. The following description is taken chiefly from a communication of Mr. David Murray to the Albany Institute, Dec. 1862, and published in its Transactions (vol. iv. p. 149). Much water is often pumped up with the petroleum, but separates from it on standing, the oil rising to the surface. The crude oil is put into large retorts of cast or wrought iron and exposed to a heat between 600° and 800°, by which all the volatile ingredients are distilled, leaving 10 or 12 per cent. of solid residue, constituting a sort of coke. The liquid thus obtained is comparatively colourless, though still retaining the strong odour of the crude oil. To separate various organic alkaloids and acids with which it is mixed, the distilled petroleum is agitated first with sulphuric acid, and afterwards with a strong solution of soda or potassa; the sulphuric acid with its dissolved impurities being drawn off, and the oil well washed with water, before the addition of the alkali, and afterwards again washed when the alkali has performed its function. The purified petroleum is now submitted to another distillation, but at first at a temperature not exceeding 120° (*Murray*), in order that only the more volatile carbohydrogens may be driven over, which are unsuitable for lamp-oil. These, being condensed, constitute what is now commonly called *naphtha*, which is used as a solvent for varnishes and caoutchouc, and for mixture with paints, a purpose which it answers as well as oil of turpentine, except for its offensive smell. It is unsuitable for lamps from its extreme volatility, its liability to smoke when burned, and the danger of explosion from the admixture of its vapour with atmospheric air. After the *naphtha*, which is equivalent to the benzine of coal tar, has all come over, the heat is increased and the distillation continued until the distilled liquid attains the sp. gr. 0·820. This is the part sold for lighting, and is by far the most important product of petroleum. The quantity of it obtained varies greatly, sometimes not exceeding 30 per cent., sometimes amounting to 80 or 90. It is clear, and of a fine deep-amber colour, and answers admirably for lighting, yielding a brighter and purer flame than perhaps any other kind of lamp-oil. If the distillation be now continued, a darker and heavier product comes over, which upon cooling deposits paraffin. The part remaining liquid, which is too impure for burning, is employed for lubricating machinery.

The oil of petroleum is said to be largely adulterated in Europe, so as to increase its density, by the addition of the heavier oils called paraffin oils, which cannot otherwise be used for the purpose of lighting. The mixture differs in its sensible properties from the pure oil only by a much stronger odour; but it is said to be much more inflammable, and consequently, dangerous. (*Journ. de Pharm.*, Juillet, 1867, p. 50.) W.

Medical Properties and Uses. Petroleum is accounted a stimulating antispasmodic, ex-

pectorant, and diaphoretic. In large quantities it may prove poisonous, as shown by a case recorded in the *Journal de Pharmacie* (Mars, 1869, p. 227), in which, after swallowing by mistake a quantity of rectified petroleum, a workman was seized almost immediately with violent inflammation of the throat, with colicky pain, and a desire to vomit, followed in an instant by a fearful tetanic seizure, and a general rigidity, attended with the most frightful cries. After a relaxation of ten minutes the symptoms returned with still greater violence; and life was probably saved only through the prompt action of the powerful emeto-cathartic medicines administered. It is occasionallly given in disorders of the chest, when not attended with inflammation. In Germany it has been extolled as a remedy for tape-worm. Schwartz's formula in such cases was a mixture of one part of petroleum with one and a half parts of tincture of assafetida, of which forty drops were given three times a day. Externally, petroleum is employed in chilblains, chronic rheumatism, affections of the joints, paralysis, and diseases of the skin, and is said to be very effectual in psora and prurigo. It is an ingredient in the popular remedy called *British oil*. (See *note*, p. 619.) The dose of Barbadoes petroleum is from thirty drops to a small teaspoonful, given in any convenient vehicle. Rangoon petroleum is probably more active, and should be given in a smaller dose. The *New York petroleum*, called *Seneca oil*, is used to a considerable extent as an external application in domestic practice. It is lighter coloured, thinner in consistence, and less sapid and odorous than the Barbadoes petroleum, and probably contains more naphtha. The finer kinds of petroleum, called naphtha, have been used with advantage in epidemic cholera by Dr. Andreosky, of the Russian army, by M. Cloquet, physician to the Shah of Persia, and by M. Moretin, of France. They gave from ten to twenty drops in half a glass of white wine or mint water. From observations made in India, there is some reason to hope that the vapour of petroleum may prove a protection against the morbid influence of marsh miasmata; as it is stated that the workmen engaged in the petroleum works, at Dibrooghur, are in an extraordinary degree exempt from the malarious diseases previously existing. (*Med. Times and Gaz.*, Oct. 1868, p. 405.) Nor would this be surprising if true, for the air of large cities is known to exercise a similar influence, probably through the smoke from their numerous fires. B.

PHLORIDZIN. This is a bitter principle, discovered by Dr. Konink, of Germany, in the bark of the apple, pear, cherry, and plum trees. It is most abundant in the bark of the root, and derived its name from this circumstance (from two Greek words, φλοιος bark, and ῥιζα a root). It is light, white, crystallizable in silky needles, of a bitter taste, soluble in about 1000 parts of cold and in all proportions in boiling water, very soluble in alcohol, scarcely soluble in ether cold or hot, dissolved without change by solutions of the alkalies, especially by ammonia, deprived of its water of crystallization at 212°, and fusible at a somewhat higher temperature. It is without acid or alkaline reaction, and consists of carbon, hydrogen, and oxygen; its formula being, according to G. Roser, when dry, $C_{42}H_{25}O_{20}$, with the addition of 4 eqs. of water when crystallized. When heated with dilute muriatic or sulphuric acid, it is converted into sugar and a peculiar substance called *phloretin*. (See *Chem. Gaz.*, viii. 392.) To obtain it, the fresh bark of the root of the apple-tree should be selected, as the dried bark is said to contain it in much smaller proportion. The bark is to be boiled for an hour or two successively in two separate portions of water, each sufficient to cover it, and the decoction set aside. At the end of thirty hours they will have deposited a considerable quantity of coloured phloridzin, which may be purified by boiling for a few minutes with distilled water and animal charcoal, filtering, repeating this process two or three times, and then allowing the solution to cool slowly. The phloridzin is deposited in the crystalline state. An additional quantity may be obtained by evaporating the decoction to one-fifth of its bulk, allowing it to cool, and purifying the substance deposited in the same manner as before.

Phloridzin is said to possess the anti-intermittent property in a high degree, and to have proved successful where quinia had failed. It was employed by Dr. Konink in the dose of 10 or 15 grains, and effected cures in several cases of intermittent fever. Dr. De Ricci recommends it very strongly as a tonic in the dyspepsia of delicate females, in the debility of children requiring a supporting treatment, and in all cases in which quinia is indicated but is not well borne. He has never known it to disagree with patients in the dose of 10 grains three or four times a day. As a tonic, 5 grains of it may be given at a dose. Though nearly insoluble in water alone, it may be readily exhibited in solution by adding to the water a few drops of spirit of ammonia. (*Dub. Quart. Journ.*, Aug. 1862.) W.

PHOSPHATE OF POTASSA. *Potassæ Phosphas.* The phosphate of potassa, which has of late come into use as a medicine, is the neutral tribasic phosphate, having the formula $2KO,HO,PO_5$, and therefore a composition precisely analogous to that of the medicinal phosphates of soda and ammonia. It is derived from the variety of phosphoric acid containing three eqs. of water, by the substitution of two eqs. of potassa for two of water, and, notwithstanding its slight alkaline reaction, is called *neutral*, in order to distinguish it from the decidedly *alkaline* tribasic phosphate, $3KO,PO_5$. It may be formed precisely as phosphate of soda is prepared (see *page* 1397); or by saturating, by means of carbonate of potassa, glacial phosphoric acid (HO,PO_5), changed by solution in water and ebullition into common phosphoric acid ($3HO,PO_5$). The medicinal phosphate of

potassa is a white, amorphous, deliquescent salt, incapable of crystallization. It has been given as an alterative in scrofula and phthisis, and in some other diseases, with supposed advantage. The dose is from ten to thirty grains three times a day, dissolved in a tablespoonful of water. B.

PHOSPHATE OF ZINC. *Zinci Phosphas.* Dr. Barnes, of London, has brought forward this salt of zinc, as having special advantages over other salts of the same metal in the treatment of nervous diseases. The theoretical ground of preference is that, in diseases of the brain there is apt to be a waste of phosphorus in the cerebral substance, and the phosphoric acid offers the means of supplying the deficiency. Phosphate of zinc may be prepared by the mutual reaction of sulphate of zinc and an alkaline phosphate. It is white, insoluble in water, but soluble in an excess of phosphoric acid. Dr. Barnes has found it peculiarly useful in the insanity occurring in the convalescence from fevers, in which he associates it with quinia, and in epilepsy attended with disorder of the uterine functions. He also uses it preferably to the sulphate of zinc in the sweats of phthisis. He finds it less liable to disturb the stomach than the sulphate. It may be given in pill, or dissolved in water acidulated with phosphoric acid, in the dose of from one to three grains. W.

PHYSALIS ALKEKENGI. *Alkekengi. Common Winter Cherry.* A perennial herbaceous plant, growing wild in the South of Europe, and cultivated in our gardens. The fruit is a round red berry, about as large as a cherry, enclosed in the calyx, and containing numerous flat kidney-shaped seeds. All parts of the plant are bitter, especially the leaves and the capsules enveloping the fruit. The berries are very juicy, and have an acidulous, bitterish taste. By drying they shrink, and become of a brownish-red colour. The bitter principle has been isolated by MM. Dessaignes and Chautard, and named by them *physalin*. It is obtained by agitating an infusion of the plant with chloroform, which extracts the bitter principle, and yields it by evaporation. To purify it, dissolve it in hot alcohol, add a little animal charcoal, filter, precipitate by water, and wash the precipitate with the same liquid. It is a light powder, white with a shade of yellow, of a taste slight at first, but in the end permanently bitter, very slightly soluble in cold water, somewhat more soluble in boiling water, and very soluble in alcohol and chloroform, especially with the aid of heat. It consists of carbon, hydrogen, and oxygen. (*Journ. de Pharm.*, 3e sér., xxi. 24.) The berries are said to be aperient and diuretic, and have been recommended in suppression of urine, gravel, and other complaints of the urinary passages. M. Gendron recommends them very highly as a febrifuge. He thinks they are most effective when allowed to ripen and begin to dry on the stem. He usually administers about three drachms daily in two doses. (*Arch. Gén.*, xxiii. 536.) A French physician has lately published a pamphlet on gout, in which he strongly recommends alkekengi as more efficacious even than colchicum. He takes the flowers and unripe fruit, dries and powders them, makes the powder into a paste with water and a little slaked lime, treats the mixture with boiling alcohol, and finally filters and evaporates the alcoholic liquid. The residue is given in the form of pill, made with solution of silicate of soda and powdered *Teucrium Chamædrys*. Five or six of the pills are taken daily. (*Braithwaite's Retrospect*, Am. ed., No. 46, p. 214.) From six to twelve berries, or an ounce of the expressed juice, may be taken for a dose; and much larger quantities are not injurious. They are consumed to a considerable extent in some parts of Europe as food. The berries of the *Physalis viscosa*, of this country, are said by Clayton to be remarkably diuretic. W.

PICHURIM BEANS. The seeds of an uncertain tree growing in Brazil, Guiana, Venezuela, and other parts of South America. The tree has been supposed to be the *Ocotea Pichurim* of Kunth (*Laurus Pichurim*, Richard, *Aydendron Laurel*, Nees); but its position in either of these genera is denied by F. Nees von Esenbeck; and the plant is now referred to the genus *Nectandra* with the specific name *Puchury*. There appear to be two varieties of *Nectandra Puchury*, one bearing larger and the other smaller fruit, and distinguished as the *major* and *minor*. Professor Carson, of the University of Pennsylvania, has had specimens of the fruit and other parts of the tree sent him, sufficient to verify the ascription of the Pichurim beans to this source. (*Am. Journ. of Pharm.*, xxvii. 385.) The beans are the kernels of the fruit separated into halves. They are ovate-oblong or elliptical, flat on one side, convex on the other, of a grayish-brown colour externally, chocolate-coloured within, of an aromatic odour between that of nutmegs and sassafras, and of a spicy pungent tast. There are two kinds, one about an inch and a half long by half an inch in breadth, the other little more than half as large, rounder, and of a dark-brown colour. The former are said by Dr. Carson to come from Brazil, the latter from Venezuela, and may be severally the product of the varieties of the tree above referred to. (*Ibid.*, p. 387.) Bonastre has found them to contain a concrete volatile oil, a fatty matter of the consistence of butter, stearin, resin, brown colouring matter, fecula, gum, sugar, and lignin. Their virtues depend on the volatile oil. In the *American Journal of Pharmacy* for Jan. 1851 (p. 1), Prof. Procter describes a liquid product brought from South America, known as "*the native oil of laurel* or *sassafras*," or "*aceyte de sassafras*," said to be obtained by making incisions in the trunk of a tree growing on the

Orinoco. As described by Prof. Procter, it is an oleo-resin, of the sp. gr. 0·898, of a light auburn colour, a peculiar penetrating odour, and an aromatic, bitterish, pungent, and somewhat camphorous taste. On distillation, almost the whole passes over in the shape of a colourless volatile oil; a small proportion only of resinous matter being left behind. This oleo-resin is conjectured to be the same as that employed for adulterating the copaiba exported from Maracaibo. It may be distinguished from copaiba by its ready solubility in alcohol of 0·838, and by the fact that its volatile oil is acted on by potassium. It is believed to be the same product as the "native oil of laurel" described by Pereira, which was obtained from Demerara, and by incisions in a large tree. Prof. Carson, on comparing with it a specimen of oil presented to him as obtained from the same tree with the fruit above mentioned, has no hesitation in considering them as identical, and, therefore, in referring the so-called native oil of laurel to Nectandra Puchury. In medical properties the pichurim beans resemble the common aromatics, and may be employed for the same purposes. In South America they are said to be used as a substitute for nutmeg, and have even been called by that name. They are rare in this country. The oil obtained from the tree is said to impart its odour to the perspiration and urine, and to be useful in rheumatism, gout, &c. The bark is sometimes employed as a tonic and febrifuge. W.

PIMPINELLA SAXIFRAGA. *Small Burnet Saxifrage. Saxifraga.* A perennial umbelliferous European plant, growing on sunny hills, and in dry meadows and pastures. The root is officinal in some parts of Europe. It has a strong, aromatic, yet unpleasant odour, and a sweetish, pungent, biting, aromatic, bitterish taste. Its active constituents are volatile oil and an acrid resin. It is considered diaphoretic, diuretic, and stomachic; and has been used in chronic catarrh, asthma, dropsy, amenorrhœa, &c. The dose in substance is about half a drachm, and in infusion two drachms. The root is used also as a masticatory in toothache, as a gargle in palsy of the tongue and in collections of viscid mucus in the throat, and externally to remove freckles. W.

PINCKNEYA PUBENS. Michaux. A large shrub or small tree, growing in South Carolina, Georgia, and Florida, in low and moist places along the sea-coast. It is closely allied, in botanical characters, to the Cinchonæ, with which it was formerly ranked by some botanists. The bark is bitter, and has been used with advantage in intermittent fever. Dr. Law, of Georgia, cured six out of seven cases in which he administered it. The dose and mode of preparation are the same with those of cinchona. The chemical composition and medical properties of this bark deserve a fuller investigation than they have yet received. W.

PISCIDIA ERYTHRINA. *Jamaica Dogwood.* Dr. William Hamilton, of Plymouth, England, in a communication to the *Pharmaceutical Journal* (iv.76, August, 1844), speaks of this plant as a powerful narcotic, capable of producing sleep and relieving pain in an extraordinary manner. He had noticed, when resident in the West Indies, the use of the bark of the root in the taking of fish, upon which, even when of a large size, it exercised a very strong narcotic effect. He was induced to try it as an anodyne in toothache, and found a saturated tincture exceedingly efficacious, not only affording relief when taken internally, but uniformly curing the pain when introduced upon a dossil of cotton into the carious tooth. The bark of the root, to be effectual, should be gathered during the period of inflorescence in April. When chewed it has an unpleasant acrimony like that of mezereon. It yields its virtues to alcohol, but not to water. The formula employed by him in preparing the tincture was to macerate an ounce of the bark, in coarse powder, in four fluidounces of rectified spirit, for twenty-four hours, and then to filter. The dose is a fluidrachm. He first tried it on himself, when labouring under severe toothache, taking the quantity mentioned in cold water on going to bed. He first felt a violent sensation of heat internally, which gradually extended to the surface, and was followed by profuse perspiration, with profound sleep for twelve hours. On awaking, he was quite free from pain, and without the unpleasant sensations which follow a dose of opium. W.

PLANTAGO MAJOR. *Plantain.* A well-known perennial herb, growing in fields, by the road-sides, and in grass-plots, and abounding both in Europe and in this country. The leaves are saline, bitterish, and austere to the taste; the root saline and sweetish. The plant has been considered refrigerant, diuretic, deobstruent, and somewhat astringent. The ancients esteemed it highly, and employed it in visceral obstructions, hemorrhages, particularly from the lungs, consumption, dysentery, and other complaints. In modern times it has been applied to similar purposes, and the root is said to have proved useful in intermittents. At present, however, it is generally believed, to be very feeble, and is little used internally. As an external application it has been recommended in ulcers of various kinds and in indolent scrofulous tumours. Among the vulgar it is still much used as a vulnerary and as a dressing for blisters and sores. The dose of the expressed juice is from one to four fluidounces. Two ounces of the fresh root or leaves may be boiled in a pint of water, and given during the day. Externally the leaves are applied whole, or in decoction. *Plantago media* and *P. lancifolia* or *rib-grass*, which are also indigenous, possess properties similar to those of P. Major, and may be used for the same purposes.

Under the name of *semen psyllii*, the seeds of several species of Plantago, growing in Europe, are sometimes kept in the shops. The best are those of *Plantago Psyllium* or *fleawort*, which grows in the South of Europe and Barbary. They are small, about a line long by half a line in breadth, convex on one side, concave on the other, flea-coloured, shining, inodorous, and nearly tasteless, but mucilaginous when chewed. They are demulcent and emollient, and may be used internally and externally in the same manner as flaxseed, which they closely resemble in medical properties. W.

PLATINUM. In 1826 Prof. Gmelin, of Tubingen, made experiments to determine the action of this metal on the economy. In 1841 Dr. Ferdinand Hoefer published some observations on the same subject. The latter experimented chiefly with the bichloride, and the double chloride of platinum and sodium. They are both poisonous; the bichloride in the dose of 15 grains, the double chloride in that of 30 grains. When a concentrated solution of the bichloride is applied to the skin, it produces violent itching, followed by an eruption. Administered internally it irritates the mucous membrane of the stomach and occasions headache. The double chloride has no action when externally applied, and, when given internally, operates on the system in a less sensible manner than the bichloride. It possesses the power of augmenting the urine. Dr. Hoefer ranks the preparations of platinum with the alteratives, by the side of those of iodine, arsenic, and gold. He considers them particularly suited to the treatment of syphilitic diseases; the bichloride to cases of long standing and inveterate, the double chloride to those which are recent. The dose of the bichloride is from half a grain to two grains twice a day, given in pill. Eight grains may be made into sixteen pills, with a drachm of the extract of guaiacum wood of the French Codex, and sufficient powdered liquorice root. Of these, one, two, or three may be taken morning and evening. The double chloride may be prepared by dissolving five grains of the bichloride and eight of pure chloride of sodium in seven fluidounces of gum-water; and the whole may be taken by tablespoonfuls in the course of twenty-four hours. For frictions on indolent ulcers, Dr. Hoefer used an ointment composed of sixteen grains of the bichloride, thirty-two grains of extract of belladonna, and an ounce of lard. (*Journ. de Pharm.*, xxvii. 213.) B.

PLUMBAGO EUROPÆA. *Leadwort. Dentellaria.* A perennial, herbaceous plant, growing in the South of Europe. It has an acrid taste, and, when chewed, excites a flow of saliva. This is particularly the case with the root, which has been long used to relieve toothache. Hence the plant derived the name of *dentelaire*, by which it is known in France. A decoction of the root in olive oil has been highly recommended for the cure of the itch. Writers differ much in their statements in relation to the activity of the plant, some speaking of it as a rubefacient, vesicatory, and caustic, and, when swallowed, as violently emetic, and liable to produce dangerous irritation of the alimentary canal; while others consider it nearly inert. Perhaps the difference may be ascribed in part to the use of the plant in the recent state in one case, and dried or long kept in the other. A crystallizable, acrid principle, called *plumbagin*, has been extracted from the root by Dulong. W.

POLYPODIUM VULGARE. *Common Polypody.* A fern belonging both to the old and new continents, and growing in the clefts of old walls, rocks, and decayed trunks of trees. The root, which is the part considered medicinal, is rather long, about as thick as a goose-quill, somewhat contorted, covered with brown, easily separable scales, furnished with slender radicles, and marked by numerous small tubercles. As found in the shops, it is sometimes destitute of the scales and radicles. Its colour is reddish-brown with a tinge of yellow, its odour disagreeably oleaginous, its taste peculiar, sweetish, somewhat bitter, and nauseous. The root of the variety growing upon the oak has been preferred, though without good reason. It was deemed purgative by the ancients, who employed it for the evacuation of bile and pituitous humours in melancholic and maniacal cases. Modern physicians have used it in similar complaints, and as a pectoral in chronic catarrh and asthma. At present, however, it is scarcely ever employed, being considered nearly inert. It was given in doses varying from a drachm to an ounce, usually in connection with cathartics. W

POLYTRICHUM JUNIPERINUM. *Hair-cap Moss. Robin's Rye.* This moss is a native of the United States, and abounds in New England. For a particular description of it, the reader is referred to a communication in the *Am. Journ. of Med. Sci.*, N. S. (xxvii. 267), by Dr. Wm. Wood, of East Windsor Hill, Connecticut, who speaks in very strong terms of its efficacy as a diuretic, having found it the most successful remedy which he has employed in the treatment of dropsy. He infuses a large handful of the whole plant in water, and allows the patient to drink freely of the tea, "the more so the better." Dr. Ariel Hunter, of Hyde Park, Vermont, has subsequently given additional testimony in its favour as a diuretic, doing good service in dysury. (*N. J. Med. and Surg. Reporter*, ix. 417.) W.

POPULUS. *Poplar.* Several trees belonging to this genus have attracted some attention in a medical point of view. In most of them the leaf-buds are covered with a resinous exudation, which has a peculiar, agreeable, balsamic odour, and a bitterish, balsamic, somewhat pungent taste. This is abundant in the buds of *Populus nigra* or the *black*

poplar of Europe, which are officinal in some parts of that continent. They contain resin and a peculiar volatile oil. The buds of *P. balsamifera*, growing in the northern parts of N. America and Siberia, are also highly balsamic; and a resin is said to be furnished by the tree, which is sometimes, though erroneously, called *tacamahac*. The virtues of the poplar buds are probably analogous to those of the turpentines and balsams. They have been used in pectoral, nephritic, and rheumatic complaints, in the form of tincture; and a liniment, made by macerating them in oil, has been applied externally in local rheumatism. The *unguentum populeum* of European pharmacy is made, according to the directions of the French Codex of 1837, by bruising in a marble mortar, and boiling in 2000 parts of lard, with a gentle fire, till the moisture is dissipated, 250 parts, each, of the fresh leaves of the black poppy, deadly nightshade, henbane, and black nightshade; then adding of the dried buds of the black poplar, bruised, 375 parts; digesting for 24 hours; straining with strong expression; and finally allowing the ointment to cool after defecation. This is an anodyne ointment, occasionally employed in Europe in painful local affections. It has been ascertained that poplar buds are capable of imparting a principle to ointments, which in a considerable degree obviates their tendency to rancidity.

The bark of certain species of poplar is possessed of tonic properties, and has been used in intermittent fever with advantage. Such is the case with that of *P. tremuloides* or *American aspen*, and of *P. tremula* or *European aspen*. In the bark of the latter Braconnot found *salicin*, and another crystallizable principle which he named *populin*. It is in these, probably, that the febrifuge properties of the bark reside. They may be obtained by precipitating a saturated decoction of the bark with solution of subacetate of lead, filtering, precipitating the excess of lead by sulphuric acid, again filtering, evaporating, adding animal charcoal towards the end of the evaporation, and filtering the liquor while hot. Salicin gradually separates, upon the cooling of the liquor, in the form of crystals. If, when this principle has ceased to crystallize, the excess of sulphuric acid in the liquid be saturated by a concentrated solution of carbonate of potassa, the populin will be precipitated. If this be pressed between folds of blotting-paper, and redissolved in boiling water, it will be deposited, upon the cooling of the liquid, in the crystalline state. The leaves also of *P tremula* afford populin, and more largely even than the bark. It is probable that both principles exist in the bark of *P. tremuloides*, and other species. Salicin is described under *Salix*. *Populin* is very light, purely white, and of a bitter, sweetish taste, analogous to that of liquorice. When heated it melts into a colourless and transparent liquid. It is soluble in 2000 parts of cold, and about 70 parts of boiling water; and is more soluble in boiling alcohol. Acetic acid and the diluted mineral acids dissolve it, and, upon the addition of an alkali, let it fall unchanged. Piria regards it as a complex body, consisting of benzoic acid, *saligenin*, and glucose. (See *Am. Journ. of Pharm.*, xxiv. 240.) Of these principles saligenin and glucose have been found in salicin; and it was inferred that, by separating benzoic acid, populin might be converted into salicin. This has been effected by Piria. When populin is boiled with baryta water or milk of lime, the benzoic acid precipitated by sesquichloride of iron, the excess of iron removed by lime, and the excess of lime by carbonic acid, the remaining liquid yields salicin on evaporation. The same conversion may be effected by heating populin with an alcoholic solution of ammonia to 212°. Piria obtained from populin 28·9 per cent. of benzoic acid. (*Pharm. Journ.*, xv. 378.) Dr. T. L. Phipson, basing his experiments upon the results of Piria, has succeeded in preparing populin artificially by combining salicin and benzoic acid. Nothing more is necessary than to dissolve the two substances in alcohol, and to concentrate the solution. Crystals are formed having all the characters of populin, and consisting of salicin and benzoic acid combined in the proportion of their equivalents. (*Chem. News*, Dec. 6, 1862, p. 278.) W.

PORTULACA OLERACEA. *Garden Purslane.* An annual succulent plant growing in gardens and cultivated grounds, in the United States, Europe, and most other parts of the globe. It has an herbaceous, slightly saline taste, and is often used as greens, being boiled with meat, or other vegetables. It is considered a cooling diuretic, and is recommended in scurvy, and affections of the urinary passages. The seeds have been thought to be anthelmintic; but they are tasteless and inert. W.

POTENTILLA REPTANS. *Cinquefoil.* A perennial, creeping, European herb, with leaves which are usually quinate, and have thus given origin to the ordinary name of the plant. The root has a bitterish, styptic, slightly sweetish taste, and was formerly used in diarrhœa, and other complaints for which astringents are usually prescribed. W.

POWDER OF ALGAROTH. *Pulvis Algarothi. Oxychloride of Antimony. Nitromuriatic Oxide of Antimony.* This powder is formed by dissolving tersulphuret of antimony in muriatic acid, assisting the action, at first, by a gentle heat, which must be gradually increased to ebullition; and then pouring the resulting solution, when cold, into a large quantity of water. By a double decomposition between the tersulphuret and acid, sulphuretted hydrogen is given off copiously with effervescence, and a solution of terchloride of antimony is formed. When this is thrown into water, the greater part of the terchloride is converted, by the elements of that liquid, into muriatic acid, which remains in solution, and teroxide of antimony, which precipitates in union with the remainder of the terchloride as the powder of Algaroth.

Properties, &c. This is a white powder, having a crystalline appearance if left long in contact with the solution from which it is precipitated. When exposed to a red heat it fuses, and forms a yellow liquid, which, on cooling, concretes into a grayish crystalline mass of a pearly aspect. Its usual composition is represented by the formula $2SbO_3,SbCl_3 + HO$. It was formerly used in the preparation of tartar emetic, but has been superseded for this purpose by the pure teroxide. It has also been used in medicine; but, owing to its unequal operation, has been properly laid aside. It is liable to contain tersulphuret of arsenic (orpiment), unless when obtained from the distilled concrete terchloride of antimony. (Larocque, *Journ. de Pharm.*, March, 1849.) B.

PRENANTHES SERPENTARIA. *Lion's Foot.* This is a perennial, indigenous herb, growing in the mountainous districts of Virginia and North Carolina. It belongs to *Syngenesia Æqualis* in the sexual system, and to the natural family of *Chicoraceæ*. The genus is characterized by its "four-flowered nodding *heads*, its cylindric *involucre* calyculate at the base, its subterete unbeaked *akenes*, its scabrous *pappus* in several series, and its naked *receptacle*." This particular species has rough dentate leaves, of which the radical are palmate, the cauline with long footstalks, sinuate pinnatifid, disposed to be three-lobed, with the middle lobe three-parted, the upper lanceolate. The racemes are terminal, somewhat panicled, short, and nodding, with an eight-cleft calyx, and twelve florets. (*Pursh.*) Dr. Darlington considers this a variety of *Prenanthes alba*. It is about two feet high, with purple flowers. Pursh speaks of it as in great repute among the inhabitants of the regions it inhabits as a remedy for the bite of poisonous serpents, and relates a case in which he had seen it used effectively. The milky juice of the plant was taken internally, and the leaves steeped in water were applied to the wound and frequently changed. In October, 1849, the author received a specimen of a plant from Dr. Newsom J. Pittman, of N. Carolina, with the information that he had employed it in ten or twelve cases of the bite of the rattlesnake with uniform success. He gave internally a decoction of the root, which is extremely bitter. This plant was the *Prenanthes Serpentaria* of Pursh. W.

PROPYLAMIA. *Propylamin. Secalia. Secalin.* Under the head of Ergota (*page* 377), allusion has been already made to a volatile alkaloid discovered by Winckler in the ergot of rye, and therefore denominated by him secalin. This has since been identified with propylamia previously discovered in herring-pickle; a fact which explains the fishy odour long known as one of the characteristics of ergot. The same alkaloid has been obtained as an artificial product from narcotina (see *page* 637), codeia, cod-liver oil, and other substances, and has been found in saline combination in the flowers of Cratægus oxyacantha, Sorbus aucuparia, and one or more species of Chenopodium. The mode of obtaining it from ergot has been described in *Part* I. (*page* 381). The following method of procuring it from herring-pickle has been published by Prof. Procter in the *American Journal of Pharmacy* (March, 1859, p. 127). Herring-pickle procured from the dealers in salt fish, having been mixed with sufficient potassa to render the liquid strongly alkaline, is introduced into a retort or alembic, and heated. The vapours are condensed in a receiver containing distilled water duly refrigerated, and the heat is continued until the distillate, as it forms, ceases to have the odour of herrings. The condensed liquid, which contains the propylamia separated by the potassa from its saline combination in the pickle, is now neutralized with muriatic acid, and carefully evaporated to dryness. Ammonia, which comes over and is condensed with the propylamia, combines like it with the muriatic acid, and the dry salt obtained is a mixture of the muriates of both these bases. This is exhausted with absolute alcohol, which dissolves the muriate of propylamia, and leaves the muriate of ammonia. If the alcoholic solution be treated with hydrate of lime, propylamia in vapour is given out abundantly with very little heat, and may be condensed in a receiver, which should be kept well cooled. The process may be simplified, as suggested by Prof. Procter in a subsequent number of the journal (May, 1859, p. 222), by acidulating the liquid in the receiver with muriatic acid, added gradually as the acid becomes neutralized, thus directly forming the muriate, which may be obtained crystallized by subsequent concentration, and, if necessary, freed from the accompanying muriate of ammonia in the manner already mentioned. In consequence of the volatility of propylamia, it is better kept in the state of the muriate; and this may either be used by the physician, or extemporaneously converted into propylamia, should it be wanted, by adding an equivalent of solution of potassa. The pure muriate may be obtained by the concentration of the alcoholic solution, formed as one of the steps of the preceding process. Propylamia is a colourless transparent liquid, of a characteristic odour, usually attended with some pungency, which may possibly be ascribed to the ammonia frequently mixed with it. It is soluble in water and alcohol, has a strong alkaline reaction, and forms crystallizable salts with the acids. If the end of a glass rod, previously dipped into muriatic acid, be held over the open mouth of a vial containing it, a white cloud of the muriate will be seen, as in the case of ammonia. Though most of the salts of propylamia are soluble in water and alcohol, the sulphate is wholly insoluble in the latter of these menstrua. (*Winckler.*) Propylamia consists of carbon, hydrogen, and nitrogen; and its formula is C_6H_9N, which is represented by one eq. of propylene and one of ammonia C_6H_6,NH_3, or one of propyl and one of amidogen C_6H_7,NH_2.

Dr. Awenarius, of St. Petersburg, Russia, first called attention to the use of propylamia in rheumatism, for which he considered it a specific; so much so that a case of doubtful rheumatism might be diagnosticated by the successful use of this remedy in the course of a few days. Between March, 1854, and June, 1856, he treated in the Hospital Kalinkin, in St. Petersburg, 250 cases of rheumatism with success. Some of the cases were acute, some chronic, many metastatic, with pericardial, pleuritic, and meningeal complications; and hemiplegic and paraplegic cases were not wanting; but all recovered. In the acute cases the pain and fever disappeared in a day or two. He mixed 25 drops of propylamia with six fluidounces of distilled water, flavoured if necessary with sugar and oil of peppermint, and gave a tablespoonful every two or three hours, taking care that the alkaloid was pure and freshly prepared. (*Ann. de Thérap.*, 1859, p. 74.) Confirmatory statements from various sources have since been published; and the remedy has been found serviceable in other painful affections. Dr. B. F. Eaton, of Barnet, Vermont, has given in the *Boston Medical and Surgical Journal* an account of a severe case of neuralgia of the face, in which the pain appeared to have been entirely subdued by it in less than 24 hours. After using it for about three days, the patient was seized with vomiting, accompanied with faintness, and excessive thirst; but whether these phenomena were the effects of the propylamia could not be determined. (See *Am. Journ. of Pharm.*, May, 1862, p. 277.) Experiments are wanting to show the precise physiological properties of this alkaloid: and how far or in what manner it may prove deleterious in overdoses. There is probably no better plan of administering the remedy than that recommended by Dr. Awenarius; namely, in watery solution. A solution of 24 drops in six fluidounces of peppermint water, with two drachms of sugar, may be given in the dose of half a fluidounce, equivalent to two drops of the alkaloid, every two hours in the more acute cases. Or 36 grains of the muriate may be substituted in the mixture for the 24 drops of this alkaloid, and 6 fluidrachms of the solution of potassa added. This would give, with each dose of the propylamia, three or four grains of chloride of potassium, which could have no material effect, and certainly none of an injurious character. W.

PRUNELLA VULGARIS. *Self-heal. Heal-all.* A small perennial labiate plant, common both in Europe and the United States, growing especially by the waysides. It is inodorous, but has an austere bitterish taste. The herb in flower was formerly used, in the state of infusion or decoction, in hemorrhages and diarrhœa, and as a gargle in sore-throat. In this country it is not employed in regular practice. W.

PSORALEA EGLANDULOSA. (*Elliot.*) P. MELILOTOIDES. (*Michaux.*) *Congo Root. Bob's Root. Samson's Snakeroot.* (See Psoralea melilotoides, *Gray's Manual of Botany*, revised ed., p. 94.) This leguminous plant, a foot or two high, which grows wild in Ohio westward to Illinois, and in Virginia southward, has been brought into notice as a remedy by Dr. John P. Mettauer, of Prince Edward's Court-House, Va. The root, which, according to Dr. Mettauer, is the most active part of the plant, is spindle-shaped, generally smaller than the little finger, and, when dry, of a light-brown colour, and corrugated on the surface. It has a feeble, pleasantly aromatic odour, and a bitterish, pungent, aromatic, and not disagreeable taste. The ligneous fibres of the root are interspersed with starchy matter, which renders it liable to the attack of worms. The leaves, which are trifoliate, with oblong-lanceolate leaflets, have a taste analogous to that of the root, and little inferior in strength. Both root and leaves yield their virtues to water and to alcohol; but the latter is the most efficient menstruum. The season for collecting the plant is when it is in flower, which, in Virginia, is from the first of June to the middle of July. To prevent the action of worms, the roots, after having been dug up, carefully washed, and then dried in the shade, should be exposed for a few days to the sun, or for half an hour to 120° F. in an oven.

Dr. Mettauer states that the psoralea is a gently stimulant tonic, with some influence over the nervous system analogous to that produced by tea. He considers it as peculiarly applicable to subacute irritations of the alimentary mucous membrane, especially when in some degree involving the mesenteric glands, and attended with diarrhœa. It has been much and very advantageously employed by the negroes of the South, in an affection known among them by the name of "poison," characterized by diarrhœa, emaciation, anorexia, exceeding dryness and huskiness of the skin, a heavily furred or unnaturally clean tongue, a hectic-like fever, thirst, sunken eyes with remarkable whiteness of the conjunctiva, a peculiar bleaching of the skin in the advanced stages, frequently cough, a small and generally accelerated pulse, depressed spirits, and great debility; symptoms which strongly indicate tuberculous deposition in the abdomen. In this affection the psoralea has proved eminently serviceable. The usual mode of exhibition is that of tincture, which may be made by digesting, for fourteen days, four ounces of the bruised or coarsely powdered root with a pint of diluted alcohol. A compound tincture is sometimes used, made by adding to the above ingredients three drachms of the bruised root of Gillenia trifoliata, half an ounce of that of Apocynum androsæmifolium, and two drachms of chamomile flowers. The dose of the tincture is from three to six fluidrachms, which may be given three times a day, in a cupful of infusion of green willow twigs or fresh leaves of the mistletoe; the former being preferred in the state of diarrhœa, the latter in cases attended

with nervous disorder and diminished urine. Dr. Mettauer recommends the psoralea also in dyspepsia, especially when attended with nausea and vomiting after meals. For the statements in this article we are indebted almost exclusively to the paper of Dr. Mettauer, contained in the *Boston Med. and Surg. Journ.* (Oct. 3, 1867, p. 185), to which the reader is referred for further information on the subject. W.

PTELEA TRIFOLIATA. *Wafer-ash. Wingseed. Shrubby Trefoil. Hop-tree.* (See *Gray's Manual of Botany*, revised edition, p. 75.) This is a shrub, six or eight feet in height, growing in rocky places from Pennsylvania to Wisconsin, and southward. General attention seems to have been first called to it by Dr. O. F. Potter, in the *St. Louis Medical Reporter* (i. 9); and to this paper, and to another by Justus Steer, Ph. D., in the same journal (May, 1867), we are indebted mainly for the following statements. The flowers have a disagreeable odour; and the fruit, which is bitter, is said to be sometimes used as a substitute for hops. The bark of the root is the part used in medicine. When dried, it comes in cylindrical rolls or quills, one or two lines in diameter, and from one to several inches long, of a light-brownish colour, irregularly wrinkled, and covered with a thin epidermis. Internally it is yellowish-white, but darkens by exposure. It has a peculiar somewhat aromatic smell, and a bitter, persistently pungent, and slightly acrid, yet not disagreeable taste. It yields its virtues to water, but more readily to alcohol. It is said to have been much employed of late, among the physicians of the Western States, in the treatment of dyspepsia, and generally in diseases requiring tonics, to which class the ptelea belongs. Dr. Potter considers it a valuable and reliable remedy. He has long used it in the debility following low fevers, and especially connected with gastro-intestinal irritation, to which it seems to be peculiarly applicable from its mild and unirritating qualities. It exercises a soothing influence on the stomach, which receives it when rejecting other tonics; while it promotes the appetite, invigorates digestion, and helps greatly to re-establish health in convalescence. Dr. Potter uses a tincture, made by macerating six ounces of the bark and half an ounce of ginger in two quarts of whisky, which he gives in the dose of one or two tablespoonfuls three times a day. (*N. Y. Med. Journ.*, ii. 184.) The bark has been examined chemically by Mr. Steer, who found it to contain, besides other ingredients, an oleo-resin, of an acrid and bitter taste, and an odour recalling that of the bark, starch, albumen, a yellow colouring substance, and salts of lime, potassa, and iron. He also extracted from it the alkaloid berberin (*berberia*), which is probably the tonic principle, while the oleo-resin may impart to the bark somewhat stimulant properties. (*Am. Journ. of Pharm.*, July, 1867, p. 337.) See also a paper by Mr. G. M. Smyser, in the same journal (1862, p. 198). W.

PULMONARIA OFFICINALIS. *Lungwort.* An herbaceous perennial, European plant, sometimes cultivated in this country in gardens. The leaves are inodorous, and have an herbaceous, somewhat mucilaginous, and feebly astringent taste. They have been considered pectoral and demulcent, and employed in catarrh, hæmoptysis, consumption, and other affections of the chest; but their virtues are doubtful, and they were probably used in pectoral complaints as much on account of the supposed resemblance of their speckled surface to that of the lungs, as from the possession of any positively useful properties. W.

PUMICE STONE. *Pumex.* A very light porous stone, found in the vicinity of active and extinct volcanoes, and believed to have been thrown up during their eruption. The pumice stone of commerce is said to be obtained chiefly from Lipari. It is used whole, in the manner of a file, for removing the outer surfaces of bodies, or for rubbing down inequalities, and, in the state of powder, for polishing glass, metals, stones, &c.; purposes to which it is adapted by the hardness of its particles. W.

PYRETHRUM PARTHENIUM. (Willd.) *Matricaria Parthenium.* (Linn.) *Chrysanthemum Parthenium.* (Persoon.) *Feverfew.* A perennial herbaceous plant, about two feet high, with an erect, branching stem, pinnate leaves, oblong, obtused, gashed, and dentate leaflets, and compound flowers in a corymb upon branching peduncles. It is a native of Europe, but cultivated in our gardens. The whole herbaceous part is used. The plant has an odour and taste analogous to those of chamomile, which it resembles also in the appearance of its flowers, and in its medical virtues. According to Zeller, a pound of it yields 4·8 grains of volatile oil. (*Cent. Blatt*, 1855, p. 205.) Though little employed, it is undoubtedly possessed of useful tonic properties. The flowers of this and of a closely resembling species, *Matricaria parthenoides* (Desf.), are said to be used in France, to a considerable extent, indiscriminately with those of the true chamomile plant, Anthemis nobilis, which they closely resemble, especially when double. They may, however, be distinguished, in this state, by their peculiar odour, their smaller receptacle, which is, moreover, rounded and flattened above, instead of being conical and somewhat pointed as in the Anthemis, and by the tubular five-toothed central florets, which in the chamomile are small, few, and scarcely visible, but, in the two species of Pyrethrum, are large, very numerous, and very long. Two other species of Pyrethrum *P. roseum* and *P. carneum*, have recently come into notice, as the source of the Persian insect powder. (See *Insect Powder*, p. 1619.) W.

PYROACETIC SPIRIT. *Pyroacetic Ether. Acetone.* This substance may be obtained by carefully distilling acetate of lime, and rectifying the product by repeated distillations

from quicklime in a water-bath, until the boiling point becomes stationary, whereby it is freed from water and empyreumatic oil. It is a colourless, volatile, inflammable liquid, having a peculiar penetrating smell, and a pungent taste like that of peppermint. Its specific gravity is 0·792, and boiling point 132°. As found in the shops, its density is not generally lower than 0·820. It is miscible in all proportions with water, ether, and alcohol, without disturbing its transparency. If it becomes turbid when mixed with water, the fact shows that it contains empyreumatic oil. It has been confounded with pyroxylic spirit, from which it is distinguished by its inability to dissolve a saturated solution of chloride of calcium, which is instantly dissolved in pyroxylic spirit. (*Scanlan.*) Its formula is C_3H_3O; while that of pyroxylic spirit is $C_2H_4O_2$. In constitution it bears considerable resemblance to alcohol. Thus, its formula doubled is $C_6H_6O_2$, and that of alcohol is $C_4H_6O_2$. It was thought at one time that the substance brought to the notice of the profession by Dr. John Hastings, of London, under the name of naphtha, as a remedy for pulmonary consumption, was pyroacetic spirit; but it now appears to be settled that what he intended was pyroxylic spirit. (See *Methylic Alcohol*, page 1642.) There is no doubt that these spirits were used indiscriminately in the therapeutic trials which grew out of the publication of Dr. Hastings' book; but no exact experiments have been made, so far as we know, to determine the precise physiological action of pyroacetic spirit. B.

In the arts, it is proposed to use acetone in the preparation of varnish. Though some substances employed for this purpose, as dammar, yellow amber, and caoutchouc, are almost insoluble in this fluid, it dissolves with great facility mastic and sandarac; and a solution of the former of these resins in pyroacetic spirit constitutes a brilliant and beautiful varnish. Wiederhold thinks that it may be advantageously used in the restoration of oil-paintings which have become deteriorated by age, in consequence of the varnish having become partially opaque. Acetone, carefully applied, immediately dissolves this opaque varnish, which afterwards redisposes itself on the picture, assuming a vitreous state upon the solidification of the solution. (*Chem. News*, March 17, 1865, p. 128.) W.

PYROGALLIC ACID. *Pyrogalline* or *Galline* (Rosing). This substance has recently acquired some importance as an agent in photography. It is one of the results of the igneous decomposition of gallic acid, and may be obtained by submitting extract of galls to the same treatment as that used for preparing benzoic acid from benzoin. The vapours of pyrogallic acid rise, and condense on the upper surface of the paper diaphragm. The chief difficulty in the process is properly to regulate the heat; as at a high temperature this acid passes rapidly into metagallic acid, and thus the product is diminished. According to Löwig, it is best prepared by heating gallic acid, previously dried at 212° F., in a glass retort, by means of a chloride of zinc bath, to 410° F., when the pure acid sublimes. Liebig recommends another method, calculated especially to obviate the effects of heat, which, with all the details, may be seen in the *Am. Journ. of Pharm.* for July, 1857 (p. 338). In the same journal (July, 1854, p. 362) are the details of a process by H. Gruneberg, of the character of the one first referred to above, by which he obtained from 50 pounds of Chinese galls 2 pounds of the acid. It is stated by MM. de Luynes and Espandieu that, in the ordinary method of obtaining pyrogallic acid, much of the acid is lost. According to Pelouze, gallic acid, when heated to 410° F., is resolved completely into carbonic and pyrogallic acids; and the proportion of the latter acid produced ought to be very nearly 75 per cent. But the processes in use yield only 25 per cent.; the pyrogallic acid itself undergoing rapid decomposition at an elevated temperature. MM. de Luynes and Espandieu have succeeded in preventing this loss by decomposing gallic acid in water under pressure, instead of dry sublimation. Gallic acid is introduced into a bronze boiler with twice or three times its weight of water; the temperature is raised to a point from 392° to 410° F., and maintained at that point for half an hour, when the liquid is allowed to cool. The boiler now contains a slightly coloured solution of pyrogallic acid. This is heated with a little pure animal charcoal, filtered, evaporated sufficiently, and set aside to crystallize. The crystalline mass obtained is somewhat coloured. To obtain it entirely white, nothing more is necessary than to distil in a vacuum. The product is quite 75 per cent. The carbonic acid escapes through the joinings of the apparatus, while the watery vapour is retained. (See *Am. Journ. of Pharm.*, Jan. 1866, p. 22.)

Pyrogallic acid is in white, shining scales, inodorous, very bitter, soluble in three and a half parts of water, readily dissolved by alcohol and ether, fusible at 239° F., and sublimable at 410° in irritating vapours. According to Rosing, of Christiania, it is always partially converted, when sublimed, into metagallic acid, to which probably it owes its acid reaction as generally found in commerce; for, when quite pure, it has no influence on litmus-paper. Rosing denied altogether its claims to be considered as an acid, and proposed to call it *pyrogalline* or *galline*. (*Journ. de Pharm.*, Juillet, 1857, p. 53.) In a subsequent memoir, however, he admits its neutralizing power, and gives as its formula $C_{12}H_6O_6$. One of its characteristic properties is its strong affinity for oxygen, in consequence of which it instantly undergoes change by contact with chlorine, iodine, bromine, and the acids which readily yield oxygen. Through the same property it rapidly reduces some of the metallic oxides; and its use in photography is based on this effect ex-

ercised on the salts of silver. Though unalterable in the air when quite dry, it is rapidly changed in solution by the absorption of oxygen, so that it may be used for ascertaining the proportion of this gas in a mixture of gases. W.

REALGAR. This is the bisulphuret of arsenic, consisting of one eq. of arsenic 75, and two of sulphur 32=107. It is found native in Saxony, Bohemia, Transylvania, and in various volcanic regions. Realgar is artificially made by melting arsenious acid with about half its weight of sulphur. (*Turner.*) Thus prepared, it is of a crystalline texture, of a beautiful ruby-red colour, of a uniform conchoidal fracture, somewhat transparent in thin layers, and capable of being sublimed without change. Native realgar is said to be innocent when taken internally, while that artificially prepared is poisonous, in consequence, according to Guibourt, of containing a little arsenious acid. Realgar is used only as a pigment. W.

RED CHALK. *Reddle.* A mineral substance of a deep-red colour, of a compact texture, dry to the touch, adhering to the tongue, about as hard as chalk, soiling the fingers when handled, and leaving a lively red trace when drawn over paper. It consists of clay and oxide of iron, and is intermediate between *bole* and *red ochre*, containing more oxide of iron than the former, and less than the latter. It is used for drawing lines upon wood, &c., and is sometimes made into crayons by levigating and elutriating it, then forming it into a paste with mucilage of gum arabic, moulding this into cylinders, and drying it in the shade. It has been used internally as an absorbent and astringent. W.

RENNET. GASTRIC JUICE. PEPSINE. As a remedial agent, the gastric juice of the inferior animals has been used in three forms; 1. that of the fresh liquid taken from the stomach, 2. that of rennet, or an infusion of the dried stomach, in wine or water, and 3. that of a preparation called pepsine.

1. *Gastric juice* is a liquid secretion of the mucous membrane of the stomach, whereby nitrogenous food is rendered soluble and capable of being absorbed, and other changes are effected essential to healthful digestion. Various methods have been employed for extracting it from the stomach for experiment, which it is unnecessary here to describe. For use in medicine, the most convenient method is to collect it from the stomachs of animals killed fasting, as the hog, sheep, and calf, and then deprive it, by filtration, of the mucus and undigested alimentary matters mingled with it. In this state it is a limpid liquid, slightly yellowish or brownish-yellow, heavier than water, of a somewhat saltish taste, and a characteristic odour, which, when the juice is heated, resembles that of soup. It usually has an acid reaction. At the temperature of 100° or lower, it has the property of dissolving nitrogenous articles of food, and, without affecting starch, of changing glucose or the sugar of grapes into lactic acid. When separated from its attendant acid, it loses in a greater or less degree this solvent power, which it recovers upon the addition of lactic or muriatic acid. The idea has been advanced that, in normal digestion, it supplies itself with the requisite lactic acid, by converting into that substance the glucose taken into the stomach, or resulting from the reaction of saliva or the gastric mucus upon starch. But in cases where no starch is taken, there must be other means of supplying the necessary acid. When the juice is heated to the boiling point, it becomes turbid, and loses the solvent property. The same change takes place more slowly at the temperature of 122° F. Strong alcohol causes a deposition of solid matter, and impairs the digestive power. Tannin produces a precipitate which has no influence on food. Some of the metallic salts, as bichloride of mercury and acetate of lead, also produce a precipitate; but this, when deprived of the metallic oxide, regains the characteristic solvent property. Pure gastric juice contains about 97 per cent. of water, 1·75 of salts, a free acid, and 1·25 of a substance, which has been considered by some chemists as a distinct organic principle, and has received the name of *pepsin*. (Boudault, *Journ. de Pharm.*, Sept. 1856, p. 162.) This principle is nitrogenous, and is believed to have the properties of a ferment, whereby the gastric juice is enabled, with the assistance of an acid, to exercise its peculiar power over food. It may be separated from the gastric juice by first precipitating this with a metallic salt, as the acetate of lead, and then decomposing the metallic precipitate by sulphuretted hydrogen, which throws down the metal as a sulphuret, and leaves the pepsin in solution. The liquid is then evaporated at a very gentle heat, and the pepsin is left in the form of a soft, viscous substance, which can with difficulty be brought to a dry state without addition. But it is very doubtful whether the substance thus procured, though it has the digestive power of the gastric juice, is a pure proximate principle; as, in the purest state in which it has been obtained, it does not yield identical results on analysis. When gastric juice is completely protected from the air, it may be kept unchanged for a long time; but, on exposure, it speedily undergoes decomposition, acquires a very offensive odour, and loses its characteristic digestive property. The juice itself is almost never used internally; but, more than forty years ago, it was employed by Dr. P. S. Physick, the celebrated surgeon of Philadelphia, with considerable success, as a local application to cancers and sloughing ulcers, with the view of removing the dead bone and flesh, correcting the offensive odour, and yielding a healthful stimulus to the diseased surface. It has also been used with success, by Dr. Ellsworth, of Hartford, Connecticut, for dissolving a portion of tough animal food, which had become impacted in the œsophagus of a lad

affected with stricture of that passage. The gastric juice of a pig was used. (*Bost. Med. and Surg. Journ.*, April 17, 1856.) The inner coat of the gizzard of the S. American ostrich is said, in the state of powder, to be used in Buenos Ayres, as a remedy in dyspepsia. (E. S. Wayne, *Am. Journ. of Pharm.*, March, 1868, p. 123.)

2. *Rennet.* This is an aqueous or vinous infusion of the dried stomach of the calf, though that of the sheep or other animal would probably answer the same purpose. It is much used, as every one knows, for curdling milk; a property which it owes to a portion of the gastric secretion, retained and dried in the mucous tissue of the stomach. To the same material it probably owes the property which it possesses of converting glucose into lactic acid; and there is little doubt that it is capable, in greater or less degree, of exercising the solvent property of gastric juice over albuminous and fibrinous food. The first of the properties just referred to suggested to Dr. James Gray, of Glasgow, the use of rennet in diabetes, with the object of promoting the conversion of any sugar of grapes that might be formed in the stomach into lactic acid, and thus preventing its entrance into the circulation in its unchanged state. He met with considerable success in this use of the remedy; and it has since been employed by others, in the same disease, with supposed advantage. Dr. Gray gave a teaspoonful of the rennet after each meal. To be efficient it must be recently prepared, and of such strength that a teaspoonful will coagulate a pint of milk in five minutes. (*Ed. Monthly Journ. of Med. Sci.*, Jan. 1853, p. 31.) Rennet seems also to have been popularly employed for promoting defective digestion, in the West of England. (*Med. Times and Gaz.*, April, 1857, p. 411.) It is highly probable that the preparation, usually employed to curdle milk, may contribute to the ready digestibility of the curds and whey, so favourite an article of diet among children in this country. Dr. Geo. Ellis gives the following method of preparing *rennet-wine*, from which he has obtained the most satisfactory results, when pepsin from inadequate preparation had failed him. Take the stomach of a calf immediately after death, cut off and reject about three inches of the upper or cardiac portion, slit the stomach longitudinally, wipe it gently with a dry napkin so as to remove as little of the clean mucus as possible, then cut it into small pieces, the smaller the better, put it into a common wine bottle, fill the bottle with good sherry, and let it stand corked for three weeks. The dose is a teaspoonful, in a wineglassful of water, immediately after each meal. It is known to be good if a teaspoonful will coagulate half a pint of milk in two minutes at 100° F. (*Dub. Med. Press*, July 16, 1862.)

3. *Pepsine.* Various attempts have been made to concentrate, and bring to a convenient form for administration, the peptic principle of the gastric juice. It must not be supposed that the substances prepared with this object, and sold under the name of pepsine, have any claim to be considered as the pure principle, which, for the sake of distinction, may be called *pepsin*. The one which approaches nearest that condition is the pepsine prepared by M. Boudault. His process is as follows. The rennet bags of sheep, quite fresh, are opened, turned inside out, and washed by a gentle stream of water; the mucous membrane is then scraped off, bruised in a mortar so as to rupture the cells, and digested for twelve hours in pure water. The infusion thus obtained is precipitated by acetate of lead, and the precipitate, consisting of pepsin and oxide of lead, is mixed with water and decomposed by sulphuretted hydrogen, which throws down the lead, leaving the pepsin in solution. The liquid, having been filtered, is evaporated, at about 100° F., to a syrupy consistence; after which sufficient perfectly dry starch is added to absorb the semi-liquid matter, and bring it to the state of a dry powder. Lactic acid is sometimes added in small proportion to the liquid before evaporation, and no doubt contributes to its efficiency. An attempt to evaporate to dryness might injure the preparation; and at best a matter would be obtained, strongly disposed to absorb moisture, and consequently to undergo putrefaction. Starch is chosen for the solidification of the syrupy mass, on account of its absorbent property, and because it is not affected by the digestive power of the pepsin. If properly prepared, 15 grains of Boudault's pepsine, with the aid of a little lactic or muriatic acid, if the former was not employed in the process, will cause the solution in water of four times its weight of fibrin at the temperature of the human body; and the amount of starch added in the process is proportioned to this result. (*Pharm. Journ.*, xvi. 472.) Much care is requisite to use fresh rennet bags, before they have begun to undergo decomposition, and not to allow the temperature used in evaporation to exceed 100° F. It is asserted, of the pepsine of Boudault, that it has the reactions of the gastric juice above referred to, and is fully capable of replacing that liquid for the purposes of digestion. It may be given either with or without lactic or muriatic acid; the addition being unnecessary when there is already sufficient acid in the stomach. A spurious substance has been sold for it; but may be distinguished by the difference of its reactions, and agency in dissolving fibrin. The genuine pepsine, dissolved in water, is precipitated by acetate of lead, tannic acid, and strong alcohol; and 15 grains of it should, in 12 hours, effect the solution of a drachm and a half of boiled white of egg, or chopped meat, in half a fluidounce of water, at 100° F. (Ballard, *Med. Times and Gaz.*, Feb 1857, p. 177.) The spurious substance is destitute of these properties. Another test of the activity of pepsine is its power of coagulating milk; and the rapidity with which it produces this effect, and the quantity required to produce a certain degree of effect, are measures of its efficiency. The process of M. Boudault essentially has been adopted in the last edition of the French Codex (1866).

The idea of employing the gastric juice, or some representative of it, in order to promote digestion, is not new; and it would be difficult to determine to whom the original use of this remedy is to be ascribed. According to Boudault, however, the application of the *principle* pepsin to this purpose was first suggested by Dr. Corvisart, of Paris. (*Journ. de Pharm.*, xxx. 169.) Boudauit's preparation has been used by many practitioners with good effects, if we may judge from the reports made in the journals. The particular condition to which it is applicable is that debility of stomach, from whatever cause arising, in which gastric juice is not produced in sufficient quantity, or of sufficient power, to enable the requisite amount of food to be digested. In such cases, the debility of the stomach is kept up by the want of due nutrition of the organ, originating in its own defective function; and it has, therefore, no power of recovering its healthy condition. Artificial digestion supplies the deficient nutriment; and the stomach, being now duly nourished, resumes its proper function. Dyspepsia, the debility of stomach following chronic gastritis, and that attendant upon convalescence, and certain exhausting diseases, such as phthisis, afford suitable occasions for its use. It is thought to have proved useful in the vomiting of pregnancy, and has been highly recommended in the diarrhœa of infancy, which often proceeds from irritation of the bowels from imperfectly digested food. The dose of Boudault's preparation is 15 grains before each meal, to be taken in powder, or suspended in soup or syrup. Boudault recommends specially the syrup of cherries, as well calculated to cover its disagreeable taste. M. Besson prefers the syrup of bitter orange peel, which he has found preferable to other vehicles by its perfume and its tonic properties. He prepares pepsine for administration in the following manner. To the liquid product obtained from fifty rennet bags, of which the evaporation is stopped when 2300 grammes remain, he adds 11 grammes of lactic acid, 100 grammes of tincture of bitter orange peel, and 110 grammes of extract of curaçoa; then filters, adds 450 grammes of sugar, dissolves, and filters. Thirty grammes of this syrup contain 15 grains of acidified pepsine. The syrup will keep a long time without change. (*Journ. de Pharm.*, 4e sér., iv. 54.) There is no incompatibility between it and other remedies usually employed in similar cases, such as the simple bitters, quinia, nux vomica, the chalybeates and opiates. W.

RESEDA LUTEOLA. *Weld. Dyers' Weed.* An annual European plant, naturalized in the United States. It is inodorous, and has a bitter taste, which is very adhesive. Chevreul obtained from it by sublimation a peculiar yellow colouring matter, which he called *luteolin*. In medicine it has been employed as a diaphoretic and diuretic, but is now neglected. On the continent of Europe it is much employed for dyeing yellow, and, before the introduction of quercitron into England, was extensively applied to the same purpose in that country. The whole plant is used. W.

RHIGOLENE. This name was given by Dr. H. J. Bigelow, of Boston, to a variety of petroleum naphtha. It is obtained by distilling petroleum, and separating the liquids of the lowest boiling point by redistillation, until a liquid is obtained which boils at about 70°. It is not pretended that this is a peculiar definite principle; on the contrary, it is probably one or more of the liquid products combined with one or more of the gaseous, so as to yield a fluid more volatile than any one previously known, and capable, consequently, of producing a greater degree of cold by its evaporation. In this respect rhigolene probably exceeds all other substances. A degree of cold 15° below zero is, according to Dr. Bigelow, obtained through the evaporation of this liquid by means of the common atomizer or "spray-producer." This is the chief use of the liquid; which may be employed, as a substitute for ether, and with still greater effect, in producing congelation of any part of the body preparatory to a surgical operation, or a great degree of cold for any other purpose. It should, when not in use, be kept in a cool place, in bottles tightly corked; as otherwise it will be rapidly evaporated. In a warm place it might break the bottles through its extreme volatility, unless the stopper should previously be driven out. It has been accused of being liable to explosion; but this has been proved not to be true by Dr. J. D. Jackson, of Danville, Ky. (*Am. Journ. of Pharm.*, July, 1865, p. 349.) If, however, the vapour should be mixed, in certain proportions, with atmospheric air, and then approached by a burning body, there might be explosion, as with other inflammable aeriform substances similarly circumstanced. W.

RHODODENDRUM CRYSANTHUM. *Yellow-flowered Rhododendron.* This is a beautiful evergreen shrub, about a foot high, with spreading branches, and oblong, obtuse, thick leaves, narrowed towards their footstalks, reflexed at the margin, much veined, rugged and deep-green upon their upper surface, ferruginous or glaucous beneath, and surrounding the branches upon strong petioles. The flowers are large, yellow, on long peduncles, and in terminal umbels. The corolla is wheel-shaped, with its border divided into five roundish, spreading segments. The plant is a native of Siberia, delighting in mountainous situations, and flowering in June and July. The leaves are the part used. When fresh, they have a feeble odour, said to resemble that of rhubarb. In the dried state, they are inodorous, but have an austere, astringent, bitterish taste. They yield their virtues to water and alcohol. They are stimulant, narcotic, and diaphoretic, producing, when first taken, increase of heat and arterial action, subsequently a diminished frequency of the pulse, and, in large doses, vomiting, purging, and delirium. They have been long em-

ployed in Siberia as a remedy in rheumatism; and their use has extended to various parts of Europe. Their action is said to be accompanied with a sensation of creeping or pricking in the affected part, which subsides in a few hours, leaving the part free from pain. They have been recommended also in gout, lues venerea, and palsy. In Siberia they are prepared by infusing two drachms of the dried leaves in about ten ounces of water, in a close vessel, and keeping the liquid near the boiling point during the night. The strained liquor is taken in the morning; and a repetition of the dose three or four days successively generally effects a cure. The remedy is not used in this country. W.

RIGA BALSAM. *Balsamum Carpaticum. Balsamum Libani.* This is a product of *Pinus Cembra*, a large tree growing in the mountainous regions and northern latitudes of Europe and Asia. The juice exudes from the extremities of the young twigs, and is collected in flasks suspended from them. It is a thin, white fluid, having an odour analogous to that of juniper, and possessing the ordinary terebinthinate properties. In this country it is very rare; but it is occasionally brought from Riga or Cronstadt in bottles. A similar product, called *Hungarian balsam*, is obtained in the same manner from *Pinus Pumilio*, growing on the mountains of Switzerland, Austria, and Hungary. It is scarcely known in the United States. W.

ROBINIA PSEUDO-ACACIA. *Locust-tree.* This well-known indigenous tree, so much valued by the farmers for fence-posts in consequence of the great durability of its wood, and so much a favourite for the beauty of its foliage and the sweetness of its flowers, is also supposed by some to possess remedial properties, and has a place in the Materia Medica of the "eclectics." The bark of the root is the most active part, and is said to be tonic, and in large doses purgative and emetic. Three cases of poisoning in children, who had eaten of the root by mistake, have been recorded. The symptoms were like those produced by an overdose of belladonna; but all the children recovered. One of them, who happened to be laboring under intermittent fever at the time, had no return of the paroxysms afterwards. (*Ann. de Thérap.*, 1860, p. 64.) These facts render caution advisable in the use of the root, yet are also well calculated to stimulate inquiry. W.

ROTTEN STONE. *Terra Cariosa.* An earthy mineral, occurring in light, dull, friable masses, dry to the touch, of a very fine grain, and of an ash-brown colour. It is obtained from Derbyshire in England, and is used for polishing metals. A particular account of it may be found in the *American Journal of Pharmacy* (Sept. 1860, p. 463). W.

SACCHARATE OF LEAD. PLUMBI SACCHARAS. *Oxalhydrate of Lead.* A salt composed of saccharic acid and protoxide of lead. Saccharic acid is obtained by the action of nitric acid on sugar. Oxalic acid is generated at the same time, which, having crystallized out of the liquid, leaves the *saccharic* or *oxalhydric* acid, which are synonymes, in solution. The saccharate of lead is made by saturating a solution of saccharic acid in water by freshly precipitated carbonate of lead gradually added. As the acid becomes saturated, the saccharate of lead falls in the form of a white powder, being insoluble in cold water, and but very sparingly soluble in that liquid boiling hot. It was first employed therapeutically by Dr. S. E. Hoskins, who used it as a solvent of urinary calculi. The neutral saccharate of lead has no effect on urinary concretions; and it is only when there is an excess of acid that it becomes effective. Dr. Hoskins, however, employed the salt in a form which he called *nitro-saccharate of lead*, prepared by dissolving the saccharate in dilute nitric acid, containing only one part of the acid in 20 parts of the mixture, filtering the solution, and gradually evaporating. The nitro-saccharate is deposited in yellow crystals of the form of regular six-sided plates or prisms. By dissolving one grain of this salt, with five drops of pure saccharic acid, in a fluidounce of distilled water, a solution was obtained, which, though slightly acid to test-paper, was perfectly bland, and was well tolerated by the conjunctiva, and by the mucous membrane of the urethra. The property, which, in connection with this blandness, gives the salt its remedial value, is that of rapidly dissolving phosphatic calculi out of the body. It was supposed that it might act in the same way in the bladder; and accordingly the solution was injected daily or every other day, in a case of phosphatic sediment, being retained each time fifty minutes, without any inconvenience whatever; and with considerable benefit to the patient. In another instance it was employed in like manner, with similar results; and enough has been ascertained by experience to justify the hope, that it may prove a serviceable remedy, used by injection, in cases of phosphatic deposition in the bladder. For the above facts we are indebted to Pereira's *Mat. Med.* (3d ed., i. 755). W.

SAGAPENUM. Though one of the officinals of the late London Pharmacopœia, Sagapenum has been omitted in the British. It belongs to the category of gum-resins. All that is known in relation to its source is, that it is the concrete juice of a plant, probably umbelliferous, growing in Persia. The plant is conjectured to be a species of Ferula, and Willdenow supposed it to be *F. Persica*, but without sufficient evidence. The drug is brought from Alexandria, Smyrna, and other parts of the Levant. It is in irregular masses, composed of agglutinated fragments, slightly translucent, of a brownish-yellow, olive, or reddish-yellow colour externally, paler internally, brittle, of a consistence somewhat resembling that of wax, and often mixed with impurities, especially with seeds more or less entire. An inferior variety is soft, tough, and of uniform consistence. It has an alliaceous

odour less disagreeable than that of assafetida, and a hot, nauseous, bitterish taste. It softens and becomes tenacious by the heat of the hand. The effect of time and exposure is to harden and render it darker. It is inflammable, burning with a white flame and much smoke, and leaving a light spongy charcoal. Pure alcohol and water dissolve it partially, diluted alcohol almost entirely. Distilled with water it affords a small quantity of volatile oil; and the water is strongly impregnated with its flavour. According to Pelletier, it contains 54·26 per cent. of resin, 31·94 of gum, 1·0 of bassorin, 0 60 of a peculiar substance, 0·40 of acidulous malate of lime, and 11·80 of volatile oil including loss. Brandes found 3·73 per cent. of volatile oil. This is pale-yellow, very fluid, lighter than water, and of a disagreeable alliaceous odour.

Medical Properties and Uses. Sagapenum is a moderate stimulant, resembling assafetida, but much inferior, and usually considered as intermediate between that gum-resin and galbanum. It has been given as an emmenagogue and antispasmodic in amenorrhœa, hysteria, chlorosis, &c., but is now seldom used. It was known to the ancients; and Dioscorides speaks of it as being derived from Media. The dose is from ten to thirty grains, and may be given in pill or emulsion. Sagapenum is also considered discutient, and has been occasionally applied externally, in the form of plaster, to indolent tumours. W.

SALEP. Though not recognised either in the U.S. Pharmacopœia or in the British, this substance deserves a brief notice, as it is frequently mentioned by writers on the materia medica, and is occasionally to be found in the shops. The name is given to the prepared bulbs of *Orchis mascula* and other species of the same genus. The *male orchis* is a native of Europe, the Levant, and Northern Africa. Its bulbs, which are two in number, oval or roundish, internally white and spongy, are prepared by removing their epidermis, plunging them into boiling water, then stringing them together, and drying them in the sun or by the fire. By this process they acquire their peculiar appearance and consistence as found in the shops. Landerer, however, denies that, as prepared in Greece or Macedonia, they are dipped in boiling water, and ascribes their horny character to their being quickly dried in a baking oven. (*Pharm. Journ.*, March, 1850.) They were formerly procured exclusively from Macedonia, Asia Minor, and Persia, but are now said to be prepared in France, and perhaps other parts of Western Europe.

Salep is in small, oval, irregular masses, hard, horny, semi-transparent, of a yellowish colour, a feeble odour, and a mild mucilaginous taste. It is sometimes kept in the state of powder. In composition and relation to water it is closely analogous to tragacanth, consisting of a substance insoluble, but swelling up in cold water (*bassorin*), of another in much smaller proportion, soluble in cold water, and of minute quantities of saline matters. It also occasionally contains a little starch. It is highly nutritive, and may be employed for the same purposes as tapioca, sago, &c. The reputation which it enjoyed among the ancients, and still enjoys in the East, of possessing aphrodisiac properties, is wholly without foundation. On account of its hardness, salep, in its ordinary state, is of difficult pulverization; but the difficulty is removed by macerating it in cold water until it becomes soft, and then rapidly drying it. W.

SANDARACH. *Sandaraca.* This is a resinous substance obtained from *Thuya articulata*, an evergreen tree growing in the North of Africa. It is in small, irregular, roundish-oblong grains or tears, of a pale-yellow colour, sometimes inclining to brown, more or less transparent, dry and brittle, breaking into powder under the teeth, of a faint agreeable odour increased by warmth, and of a resinous, slightly acrid taste. It melts with heat, diffusing a strong balsamic odour, and easily inflames. It is almost entirely soluble in ordinary alcohol, and entirely so in that liquid when anhydrous, and in ether. Heated oil of turpentine also dissolves the greater part of it, but very slowly. According to Unverdorben, it consists of three resins, varying in their relations to alcohol, ether, and oil of turpentine. The *sandaracin* of Geise, which remains after sandarach has been exposed to the action of ordinary alcohol, is a mixture of two of these resins. Sandarach was formerly given internally, and entered into the composition of various ointments and plasters. At present it is used chiefly as a varnish, and as incense; and its powder is rubbed upon paper to prevent ink from spreading, after letters have been scratched out. W.

SANICULA MARILANDICA. *Sanicle.* An indigenous, umbelliferous, perennial, herbaceous plant, two or three feet in height, growing in woods and thickets, in almost all parts of the United States, as far south as South Carolina. For its botanical character, see *Eaton's Botany*, and *Torrey and Gray's N. Am. Flora* (vol. i. p. 601). The root is the part used, and is popularly known in some parts of the country by the name of *black snakeroot*. It is fibrous and of an aromatic taste, and has been used as a domestic remedy in intermittent fever. Dr. J. B. Zabriskie has found it highly effectual in chorea. He considers it most efficient in substance, and gives the powder to children eight or ten years old in the dose of half a drachm three times a day. (*Am. Journ. of Med. Sci.*, N. S., xii. 374.) W.

SANTALUM ALBUM ET CITRINUM. *Sandal wood. Saunders.* There are three kinds of wood known by the name of santalum or saunders;—1. *santalum rubrum*, or red saunders, from Pterocarpus santalinus, already described in this work (*page* 772) under

the officinal name of *Santalum*; 2. *santalum album*, or *white saunders*, from the *Santalum album* of Linnæus, growing in the East Indies, the S. Pacific Islands, and South America; and 3. *santalum citrinum*, or *yellow saunders*, formerly supposed to be the inner wood of the tree of which the outer constituted white saunders, but now stated to be from a different species, *S. freycinetianum* of M. Gaudichaud, growing in the Sandwich Islands, the Feejee Islands, the Marquesas, on the coast of Malabar, &c. It is this species which supplies the sandal wood so highly valued by the Chinese. Both kinds have a very agreeable aromatic odour. The white is thought by the East India physicians to be refreshing, and useful in remittent fevers, gonorrhœa, and other complaints. It was formerly used in European pharmacy, and still enters into certain compound syrups, confections, &c. The Chinese employ the yellow saunders chiefly as a perfume, burning it in their temples, sick-chambers, &c., and obtain from it a volatile oil by distillation, which they mix with oil of roses. This variety was also formerly used in Europe, and praised as cordial and alexipharmic. The *three saunders* were not unfrequently combined in the same preparation. (*Mérat et De Lens.*) A volatile oil is obtained by distillation from a variety of yellow sandal wood, the product of *S. myrtifolium*, growing in continental India (Lindley, *Flor. Med.*, p. 323), which is stated by Dr. Thos. B. Henderson, as the result of his own experience, to be a specific in gonorrhœa, equal if not superior in efficacy to copaiba, without its inconveniences. It is pleasant to the taste and grateful to the stomach, and perfectly harmless even in large doses. The odour of the oil is slightly perceptible in the urine. Its effects are observable, in susceptible cases, a few days after beginning with its use. The formula employed by Dr. Henderson is from 20 to 40 minims, diluted with three measures of rectified spirit, and flavoured with oil of cinnamon, and given three times a day. (*Med. Times and Gaz.*, June, 1865, p. 571.) W.

SAPONARIA OFFICINALIS. *Soapwort.* A perennial herbaceous plant, growing wild in this country in the vicinity of cultivation, but probably introduced from Europe. It is commonly known by the vulgar name of *bouncing bet*. It is one or two feet high, with smooth, lanceolate leaves, and clusters of conspicuous whitish or slightly purplish flowers, which appear in July and August. The root and leaves are employed. They are inodorous, and of a taste at first bitterish and slightly sweetish, afterwards somewhat pungent, continuing long, and leaving a slight sense of numbness on the tongue. They impart to water the property of forming a lather when agitated, like a solution of soap, whence the name of the plant was derived. This property, as well as the medical virtues of the plant, resides in a peculiar proximate principle, obtained from the root by Bucholz, and called by him *saponin*. This principle constitutes, according to Bucholz, 34 per cent. of the dried root, which contains also a considerable quantity of gum and a little bassorin, resin, and altered extractive, besides lignin and water. Saponin is obtained, though not absolutely pure, by treating the watery extract with alcohol and evaporating. It is brown, somewhat translucent, hard and brittle, with a sweetish taste, followed by a sense of acrimony in the fauces. It is soluble in water and officinal alcohol, but is insoluble in anhydrous alcohol, ether, and the volatile oils. Its watery solution froths when agitated. This principle has been found also in various other plants, as different species of Silene, Dianthus, Lychnis, and Anagallis. (*Journ. de Pharm.*, 3e sér., x. 339.) It is said to possess poisonous properties. Soapwort has been used in Germany as a remedy in venereal and scrofulous affections, cutaneous eruptions, and visceral obstructions. It appears to act as an alterative, like sarsaparilla, to which it has been deemed superior in efficacy by some physicians. The plant is given in the form of decoction and extract, which may be freely taken. From two to four pints of the decoction daily are recommended in lues. The inspissated juice, given in the quantity of half an ounce in the course of a day, is said by Andry generally to cure gonorrhœa in about two weeks, without any other remedy. According to Dr. Bonnet and M. Malapert, this and other plants containing saponin are capable of producing poisonous effects. (*Ibid.*) M. Eugene Pélikan, upon experimenting with saponin from various sources upon the lower animals, has found it to possess the extraordinary power, when injected into the cellular tissue, of producing paralysis of the muscles, entirely local in its nature, that is, without the intervention of the general nervous system, and in a normal state of all the functions of sensibility and motility in the parts not submitted to its action. In the parts acted on, sensibility and motility are both suspended, and the paralysis is followed by rigidity. Reflex motion is destroyed, as no irritant applied to the extremity has the least power of provoking contraction. The same phenomena are evinced, though the circulation be suspended by tying the vessels of the limb; and the ligation of the aorta even accelerates the result. It would appear that a substance possessing such extraordinary powers might play an important part in therapeutics. W.

SARCOCOLLA. A peculiar vegetable product, exuding spontaneously from the *Penæa Sarcocolla*, *P. mucronata*, and other species of Penæa, small shrubs growing at the Cape of Good Hope, in Ethiopia, Arabia, &c. It is in the form of small, roundish, irregular grains, sometimes agglutinated in masses, friable, opaque or semi-transparent, of a yellowish or brownish-red colour, inodorous unless heated, when they have an agreeable smell, and of a peculiar, bitter, sweetish, and acrid taste. Sarcocolla, according to Pelletier, consists of 65·3 per cent. of a peculiar substance, considered by Dr. Thomson as holding an interme-

diate place between gum and sugar, and called *sarcocollin* or pure sarcocolla, 4·6 of gum, 3·3 of a gelatinous matter having some analogy with bassorin, and 26·8 of lignin, &c. It is said to be purgative, but at the same time to produce serious inconvenience by its acrid properties. The Arabian physicians used it internally; and by the ancients it was employed as an external application to wounds and ulcers, under the idea that it possessed the property of agglutinating the flesh, whence its name was derived. It is out of use. W.

SARRACENIA. *Side-saddle Plant. Fly-trap.* Two Southern species of this curious indigenous genus of plants, *S. flava* and *S. variolaris*, were brought into notice by Dr. E. P. Porcher, in a communication published in the *Charleston Medical Journal and Review*. Dr. Porcher states that the roots (rhizomes) of these plants have long been used as a domestic remedy by the inhabitants of the lower portions of South Carolina. The medicine is believed in that region to possess extraordinary powers in dyspepsia; and he received reports, from persons entirely deserving of confidence, of its efficacy in sick-headache, waterbrash, gastralgia, abdominal distension, &c. In trying the remedy upon himself, he found it to be bitter and astringent to the taste, and, in its effects on the system, stimulant to the stomach, the circulation, and in some degree to the brain, and at the same time to a certain extent diuretic, and disposed to operate mildly on the bowels. From the results stated by Dr. Porcher, we should infer that the medicine is a stimulating tonic, with some tendency to act on the brain; and probably well suited to cases of dyspepsia dependent on debility of stomach. Professor Sheppard submitted the root to chemical examination, and found it to contain liguin, colouring matter, resin, an acid salt of lime, and a salt probably of an organic alkali. The best mode of administration seems not to have been well determined. Invalids chew it as they would chew tobacco; and from Dr. Porcher's statements we should infer that it might be appropriately given in powder, in the dose of half a drachm three or four times a day. (See *Wood's Quarterly Retrospect*, ii. 78.) Much attention has recently been paid to another species of Sarracenia, the *S. purpurea*, in the treatment of smallpox, under the impression that it had the power of very favourably modifying that disease, and, indeed, of materially shortening its course. The claims made in favour of this remedy were so much in opposition to all that we knew, whether of the medicine or the disease, that we had no hesitation in expressing our conviction, that the apparent efficacy of the remedy was simply owing to its employment in those cases of modified smallpox, which, in consequence of a partial protection of the system, either through vaccination or a previous attack of smallpox, generally run a short, and almost always a favourable course; and subsequent experience has fully determined its entire want of any curative influence over the disease. The root was exhibited in infusion or decoction, made in the proportion of half an ounce to a pint of water, and given in the dose of a wineglassful every three hours. The whole herbaceous part of the plant, having been found to possess the same bitter taste was afterwards used in the same manner and dose For a description of this species of Sarracenia, in all its relations, see a paper by Prof. Bentley, in the *Pharmaceutical Journal* for Jan. 1863 (p. 294). The root of the S. purpurea has been chemically examined by M. Stan. Martin, who found in it, 1. an alkaloid which he proposes to name *sarracenine;* 2. a resin; 3. a yellow colouring principle; 4. extractive; 5. substances which constitute the frame-work of plants. Sarracenine (*sarracenina*) is white, is soluble in alcohol and the ethers, combines with acids to form salts, and with sulphuric acid forms handsome needles, which are bitter, and communicate this taste to its menstrua. (*Ann. de Thérap.*, 1866, p. 73.)

Under the name of *trumpet-plant*, with various synonymes, as *fly-catcher*, *huntman's cup*, &c., a yellow-flowered plant of Florida was brought to public notice in the *American Journal of Pharmacy* (July, 1869, p. 292), by Dr. J. Dabney Palmer, who, having experimented with the root therapeutically, at the request of neighbours, ascertained that it possesses extraordinary powers in the cure of diarrhœa. Some of the cases in which it was given were of long standing and very obstinate, others recent; but all yielded to the remedy; and in no case were more than four ounces of the tincture required to effect a cure. A few doses were generally sufficient. The tincture was prepared by macerating, for fourteen days, four ounces of the root with two pints of alcohol, then expressing and filtering. The dose was a teaspoonful after each evacuation. In a subsequent communication to the same journal, Dr. Palmer states that the plant is a Sarracenia, and designates it as the *S. flava*, which is one of the species mentioned above as having been employed by Dr. Porcher. It grows abundantly in Florida, near Monticello. It has a spotted hood, and the flower is greenish-yellow. W.

SASSA GUM. This name has been applied by Guibourt to a gum, occasionally brought into market from the East, and answering so exactly to Bruce's description of the product of a tree which he calls *sassa*, that there is reason to believe in their identity. According to Guibourt's description, it is in mammillary masses, or in convoluted pieces resembling an ammonite, of a reddish colour and somewhat shining surface, and more transparent than tragacanth. Its taste is like that of tragacanth, but slightly acrid. When introduced into water, it becomes white, softens, and swells to four or five times its original bulk; but it preserves its shape, neither like tragacanth forming a mucilage, nor like Bassora gum separating into distinct flocculi. It is rendered blue by iodine. W.

SASSY BARK. This bark is interesting chiefly from its employment by the natives of Western Africa as an ordeal in their trial for witchcraft or sorcery. Specimens sent to this country from Liberia, were first examined by Mr. C. A. Santos, who published his observations in the *Am. Journ. of Pharm.* (xxi. 97, April, 1849). Other specimens both of the bark and the plant producing it, afterwards came under the notice of Professor Procter, who was thus enabled to determine as well the chemical characters as the botanical source of the product. His papers on the subject are contained in the same journal (xxiii. 301, and xxiv. 195); and in the last is given a botanical description of the tree. To these papers the reader is referred for particular information on the subject. The bark was thought to be the product of a previously undescribed species of *Erythrophleum*, for which Prof. Procter proposed the name of *E. judiciale*. It appears, however, from a note of Prof. Lindley, published in the *Pharmaceutical Journal* for January, 1857 (p. 373), that the tree had been previously described under two specific names, having been noted in Hooker's *Niger Flora* (p. 329) as the *Erythrophleum Guineense* of Don, and the *Fillæa suaveolius* of Guillemin and Perottet's Flora of Senegal; facts, of course, unknown to Prof. Procter when his papers were written. It is a large tree with spreading branches, doubly pinnated leaves, flowers in spike-like racemes, and leguminous fruit. The bark is in pieces more or less curved, with or without epidermis, in the former case somewhat fissured externally, of a dull-red colour diversified by whitish spots, brittle, presenting when cut transversely numerous fawn-coloured spots surrounded by reddish-brown tissue, nearly inodorous, of an astringent taste, and, according to Mr. Santos, of the sp. gr. 1·054. Prof. Procter found it to contain tannic acid, insoluble apotheme analogous to that of rhatany, a red colouring matter formed by a combination of the two preceding constituents, gallic acid, gum, a little resin, fatty matter, various salts, and a peculiar substance precipitable by tannic acid, and soluble in alcohol and chloroform. He did not isolate the active principle. The bark yields its virtues to water. In reference to its effects on the system it has been considered as emetic and cathartic, with some influence over the cerebral functions; but little was certainly known. Professor Procter found three grains of the aqueous extract, given to a cat, to produce prostration, frothing at the mouth, dilatation of the pupils, and total loss of inclination to eat. Largely taken the bark was known often to cause death. The powder snuffed up the nostrils occasions violent sneezing. Some experiments made with it by Drs. S. Weir Mitchell and W. A. Hammond have given us more precise knowledge in regard to its properties. From these it appears to be nauseating and emetic, narcotic, and astringent, but without any cathartic power. The same writers give the following as the result of the observations of Dr. Savage made in Africa, and communicated to them. When the bark is chewed, it causes a feeling of constriction in the fauces, attended with prickling, and followed by numbness. A strong infusion or decoction occasions stricture across the brow, severe pain in the head, coma, and death. Independently of its use by the natives as an ordeal poison, it is sometimes employed by them as a remedy in dysentery, diarrhœa, and colic. Dr. Savage himself has known it to be successful in intermittent fever, dysentery, and diarrhœa. A grain of the watery extract was given for a dose every three hours. (*Charleston Med. Journ.*, Nov. 1859, p. 735.) W.

SATUREJA HORTENSIS. *Summer Savory.* An annual labiate plant, growing spontaneously in the South of Europe, and cultivated in gardens as a culinary herb. It has an aromatic odour and taste, analogous to those of thyme, and was formerly used as a gentle carminative stimulant; but is now employed only to give flavour to food. *S. montana* or *winter savory*, which is also cultivated in gardens, has similar properties. W.

SAURURUS CERNUUS. *Lizard's Tail.* (See *Gray's Manual of Botany*, p. 383.) A perennial, herbaceous plant, growing in low places, on the borders of ponds, in most parts of the United States, but, according to Eaton, especially abundant in New York, west of Cayuga Lake. It received its name from its supposed resemblance to a lizard. The whole plant has a heavy, disagreeable, yet somewhat aromatic odour. Dr. D. L. Phares, of Newtonia, Miss., speaks of it as being much used in some parts of the country, both in regular and domestic practice, as a soothing, discutient cataplasm. He considers it "laxative, antispasmodic, sedative, and slightly astringent," and for many years has employed it largely, and with most satisfactory results, in irritation and inflammation of the kidneys, bladder, prostate, and urinary passages generally. He considers it peculiarly applicable to cases attended with strangury. It is generally acceptable to the stomach. Dr. Phares uses it both externally and internally. He gives it in strong infusion, made with the plant whether fresh or dried, of which from one to four ounces may be given every fifteen or thirty minutes, or three or four times a day, according to the urgency of the symptoms. (*Am. Journ. of Pharm.*, Sept. 1867, p. 468; from *Atlanta Med. and Surg. Journ.*, July, 1867.) W.

SCOLOPENDRIUM OFFICINARUM. Smith. *Asplenium Scolopendrium*. Linn. *Harts-tongue.* A fern indigenous in Europe and America. Its vulgar name was derived from the shape of its leaves, which were the part formerly used in medicine. They have a sweetish, mucilaginous, and slightly astringent taste, and, when rubbed, a disagreeable oily odour. They were used as a deobstruent in visceral affections, as an astringent in hemorrhages and fluxes, and as a demulcent in pectoral complaints; but their properties are feeble, and they have fallen into neglect. W.

SCROPHULARIA NODOSA. *Figwort.* The root of the *knotty-rooted figwort* is perennial, tuberous, and knotty; the stem is herbaceous, erect, quadrangular, smooth, branching, and from two to three feet high; the leaves are opposite, petiolate, ovate-cordate, pointed, sharply toothed, veined, and of a deep-green colour; the flowers are small, dark-purple, slightly drooping, and borne on divided peduncles in erect terminal branches. The plant is a native of Europe, where it grows in shady and moist places, and flowers in July. The leaves, which are the part used, have when fresh a rank fetid odour, and a bitter, somewhat acid taste; but these properties are diminished by drying. Water extracts their virtues, forming a reddish infusion, which is blackened by the sulphate of the sesquioxide of iron. Walz has obtained from them two proximate principles, which he names respectively *scrophularin* and *scrophularosmin*. (Mayer, *Am. Journ. of Pharm.*, July, 1863, p. 295.) Figwort leaves are said to be anodyne and diuretic, and to have repellent properties when externally applied. They were formerly considered tonic, diaphoretic, discutient, anthelmintic, &c., and were thought to be useful in scrofula. They are at present very little employed; but in Europe are sometimes applied, in the form of ointment or fomentation, to piles, painful tumours and ulcers, and cutaneous eruptions. W.

SECALE CEREALE. *Rye.* Syria, Armenia, and the southern provinces of Russia have been severally indicated as the native country of rye. The plant is now cultivated in all temperate latitudes. The *grains* consist, according to Einhof, of 24·2 per cent. of envelope, 65·6 of flour, and 10·2 of water. The *flour*, according to the same chemist, consists of 61·07 per cent. of starch, 9·48 of gluten, 3·28 of albumen, 3·28 of uncrystallizable sugar, 11·09 of gum, 6·38 of vegetable fibre, besides 5·62 of loss, comprising an acid, the nature of which was not determined. Rye flour has been much used, in the dry state, as an external application to erysipelatous inflammation, and other eruptive affections, the burning and unpleasant tingling of which it tends to allay, while it absorbs the irritating secretions. In the form of mush, it is an excellent laxative article of diet, and, mixed with molasses, it may be given with great advantage in hemorrhoids and prolapsus ani, connected with constipation. Rye carbonized by heat, with exclusion of the air, has been highly recommended as a tooth-powder. W.

SEDUM ACRE. *Biting Stone-crop. Small Houseleek.* A small, perennial, succulent European plant, growing on rocks and old walls, with stems about as long as the finger, and numerous very minute leaves. It is inodorous, and has a taste at first cooling and herbaceous, afterwards burning and durably acrid. Taken internally it vomits and purges, and applied to the skin, produces inflammation and vesication. The fresh herb and the expressed juice have been used as an anti-scorbutic, emetic, cathartic, and diuretic, and have been applied locally to old ulcers, warts, and other excrescences; but the plant is at present little employed. It has recently been recommended in Germany as a remedy in epilepsy. Other species are less acrid, and are even eaten as salad in some parts of Europe. Such are *Sedum rupestre* and *S. album*. *S. Telephium* was formerly employed externally to cicatrize wounds, and internally as an astringent in dysentery and hæmoptysis; and is still esteemed by the common people in France as a vulnerary. W.

SELINUM PALUSTRE. (*Linn.*) *Peucedanum montanum.* (Lindley, *Flor. Med.*) *Marsh Parsley. Persil de marais.* (*Fr.*) This is an umbelliferous plant, belonging to Pentandria Digynia in the Linnæan system. It is herbaceous, with a fleshy, lactescent root, from which rises annually a single fistulous stem, about four feet high, furnished with large, soft, smooth, bipinnate or tripinnate leaves, and branching at top, with terminal umbels, each consisting of thirty small white flowers. The plant frequents low wet grounds in the North of Europe. The root is the part used. This, when dried, is of a brown colour externally, of a strong aromatic odour, and an acrid pungent, aromatic taste. The powder is of a light grayish-yellow colour. Analyzed by Peschier, it was found to contain a volatile oil, a fixed oil soluble in ether and alcohol, gum, a yellow colouring substance, a nitrogenous, mucoso-saccharine principle, a peculiar acid which he calls *selinic*, phosphate of lime, and lignin. The root of Selinum palustre has long been a popular remedy for epilepsy in the Russian Province of Courland; and, having in 1806 attracted the attention of Dr. Trinius, a Russian physician, was by him in 1818 brought before the notice of the profession, and afterwards acquired some reputation in the treatment of that disease. It did not, however, long retain this reputation, and in a few years seems to have been quite forgotten. More recently its use has been revived by Dr. Herpin, who published a memoir upon the subject in 1859, speaking in decidedly favourable terms of its efficiency. In relation to its physiological effects, it seems to exercise no very obvious influence on the system, sometimes acting as an aperient, in a very few instances causing temporary nausea or gastric uneasiness, but in many cases passing through the alimentary canal without apparent effect, and never, however long continued, producing any derangement of the general health. It seems to act favourably on the menstrual function, restoring its regularity, and relieving the pains often attendant on it. In speaking of its use in epilepsy, Dr. Herpin ranks it as the fourth in value, estimating oxide of zinc, sulphate of copper, and valerian, in the order of their succession, and next Selinum. He has also used it with apparent advantage in hooping-cough, and recommends its trial in other nervous affections. The commencing dose in epilepsy is from 20 to 30 grains

three times a day, taken before breakfast and dinner, and at bedtime, and increased by one-half every week, until the original dose is quadrupled; after which it may be continued for six weeks or longer. For children the dose is to be diminished according to the age. (*Journ. de Pharm.*, Juillet, 1859, p. 16.) W.

SEMPERVIVUM TECTORUM. *Common Houseleek.* A perennial, succulent, European plant, growing on rocks, old walls, and the roofs of houses, and remarkable for its tenacity of life. It is occasionally cultivated in this country as an ornament to the walls of houses, or as a domestic medicine. The leaves, which are the part used, are oblong, pointed, from half an inch to two inches in length, thick, fleshy, succulent, flat on one side, somewhat convex on the other, smooth, of a light-green colour, inodorous, and of a cooling, slightly saline, astringent, and sourish taste. They contain a large proportion of supermalate of lime. They are employed in the recent state and bruised, as a cooling application to burns, stings of bees, hornets, &c., ulcers, and other external affections attended with inflammation. The juice is said to cure warts. W.

SENECIO VULGARIS. *Common Groundsel.* An annual European plant, introduced into this country, and growing in cultivated grounds. The whole herb is used, and should be gathered while in flower. It has, when rubbed, a peculiar rather unpleasant odour, and a disagreeable, herbaceous, bitterish, and saline taste, followed by a sense of acrimony. It is emetic in large doses, and has been given in convulsive affections, liver complaints, spitting of blood, &c., but is now very little used. The bruised herb is sometimes applied externally to painful swellings and ulcers. The plant is employed also as food for birds, which are fond of it. Other species of Senecio have been medicinally used; and an indigenous species, the *S. aureus* or *ragwort*, is said by Schoepf to be a favourite vulnerary with the Indians. The "eclectics" consider it emmenagogue, and use it not only to stimulate the function, but to regulate it when in excess or otherwise deranged. They also believe it to possess diuretic properties, and to be useful in disorders of the urinary organs. They give the name of *senecin* to a preparation made by precipitating the tincture with water; but this name should be reserved for the active principle when discovered. The whole plant is used in decoction or infusion, which may be taken freely. W.

SIENNA. *Terra di Sienna.* An argillaceous mineral, compact, of a fine texture, very light, smooth, and glossy, of a yellowish-brown or coffee-colour, leaving a dull-orange trace when moistened and drawn over paper. By calcination it assumes a reddish-brown colour, and is then called *burnt sienna*. In both the raw and burnt states it is used in painting. The best sienna is brought from Italy, but an inferior kind is found in England. W.

SILENE VIRGINICA. *Catchfly. Wild Pink.* An indigenous perennial plant, growing in Western Virginia, the Carolinas, and in the States beyond the Alleghany mountains. Dr. Barton, in his "Collections," states that a decoction of the roots is said to be efficacious as an anthelmintic. We are told that it is considered poisonous by some of the Indians. *S. Pennsylvanica*, which grows in the Eastern section of the Union, from New York to Virginia, probably possesses similar properties. W.

SILEX, PULVERIZED. SILEX CONTRITUS. *Lond. Silicic Acid.* In operations of pharmacy, substances are sometimes employed whose action is exclusively mechanical. Thus, in the U. S. Pharmacopœia, sand was used in preparing oil of amber and the fluid extract of rhubarb, and carbonate of magnesia is now used in forming several of the medicated waters. The use of the same carbonate was also directed in the London Pharmacopœia of 1836, in alternative processes for preparing several of these waters. Mr. R. Warington objected to the use of this carbonate, as being dissolved to an injurious extent, and proposed to substitute porcelain clay, or pulverized silica, glass, or pumice stone. The London College, probably influenced by this objection, abandoned, in its Pharmacopœia of 1851, the use of carbonate of magnesia, and substituted finely pulverized silex, under the name of *Silex Contritus*. This powder may be conveniently obtained from *colourless* quartz or rock-crystal. In order to render the mineral more easily pulverizable, it is advantageous to heat it to redness, and quench it in water. It may then be reduced to fine powder in a porphyry or agate mortar. The London College prepared all the medicated waters, except two, from the volatile oils of the plants, in addition to the method of distillation with water from the plants themselves. When the volatile oils were used, pulverized silex was directed as a mechanical agent. The oil was rubbed up first with the silex and then with the water, and the whole was filtered. The silex acted by minutely dividing the oil and diffusing it through water, and by the subsequent filtration, was entirely removed.

Pulverized silex is a harsh, white, tasteless powder, insoluble in water and most other solvents. Its sp. gr. is 2·66. In composition it is a teroxide of silicon, SiO_3. A protoxide (SiO) has been discovered by Wöhler. (*Chem. Gaz.*, May 15, 1857.) *Silicon* is a non-metallic element, which has been obtained in three allotropic states, called amorphous, graphitoidal, and octohedral silicon; the first corresponding to charcoal, the second to graphite, and the third to diamond. The octohedral crystallizes like diamond with curved facets, is hard enough to scratch glass but not topaz, and has the sp. gr. 2·49. B.

SILICATE OF MAGNESIA, HYDRATED. A mineral used in France for the manufacture of smoking pipes, which, though known by this name to science, is probably a silicate of magnesia and lime. It has been brought into notice as a medicine by M. Garraud, a distinguished physician of Laval, who, struck with its resemblance to subnitrate of bismuth, being like it white, tasteless, and insoluble, was induced to use it as a substitute for that medicine in obstinate choleraic diarrhœa, and met with so much success as to induce him to make the remedy public. M. Trousseau employed it also with great success in numerous cases of diarrhœa. It is reduced to fine powder, and given in doses of from one to four drachms a day. It no doubt acts mechanically, either as an absorbent or a protective of the intestinal coats, and has the advantage over the subnitrate of being innocent under all circumstances. (*Journ. de Pharm.*, 4e sér., iii. 385.) W.

SILICATE OF SODA. *Sodæ Silicas. Soluble Glass.* This is the salt employed by MM. Socquet and Bonjean, in conjunction with benzoate of soda, in the treatment of gout and rheumatism, for the purpose of eliminating uric acid by the urine. (See *page* 1542.) It is made by fusing one part of silica and two of dried carbonate of soda, mixed in powder, in an earthenware crucible, and pouring out the fused mass on a stone slab to cool. This is pulverized, and treated with boiling water, to dissolve the soluble part. The solution is filtered and concentrated, so as to form crystals on cooling. These are then purified by dissolving them in water heated to 100°, filtering the solution, and concentrating it so that it may recrystallize. Silicate of soda is supposed to promote the discharge of uric acid by the kidneys; while the benzoate of soda transforms the same acid into hippuric acid. This action of the latter salt is doubtful; as it is well known that benzoic acid, when taken, is always changed into hippuric acid, the presence of which in the urine is more plausibly attributed to the medicine than to the transformation of uric acid. B.

Silicate of potassa, which may be prepared in the same way as the salt of soda, and like it is soluble, has been employed for the same purposes by M. Vanden Corput, who thinks it preferable to silicate of soda, as it acts more promptly and energetically in bringing about alkalinity of the urine. He published an article upon the therapeutic use of these salts, so early as 1849, and long anticipated MM. Socquet and Bonjean. (*Ann. de Thérap.*, 1865, p. 236.) Another use of soluble silicate of potassa, which, like the salt of soda, is known in commerce as *soluble glass*, has been proposed by Prof. Shun; as a substitute, namely, for starch, dextrin, and plaster of Paris, in the preparation of immovable dressings in the case of certain fractures of the limbs, and diseased joints. It i applied, of a syrupy consistence, by means of a brush, to the bandages, upon which it rapidly hardens, requiring only five or six hours for this result. The facility of removing it by means of hot water is another advantage which it possesses over the other dressings. (*Journ. de Pharm.*, 4e sér., iv. 52.) W.

SISYMBRIUM OFFICINALE. Scopoli. *Erysimum officinale.* Linn. *Hedge Mustard.* A small annual plant, growing in the United States and Europe, along the roadsides, by walls and hedges, and on heaps of rubbish. It has an herbaceous, somewhat acrid taste, which is strongest in the tops and flower-spikes, and resembles that of mustard, though much weaker. The seeds have considerable pungency. The herb is said to be diuretic and expectorant, and has been recommended in chronic coughs, hoarseness, and ulceration of the mouth and fauces. The juice of the plant may be used mixed with honey or sugar, or the seeds may be taken in substance. *Sisymbrium Sophia*, or the *flix weed*, was formerly officinal. It is of a pungent odour when rubbed, and of an acrid biting taste. The herb has been used externally in indolent ulcers, and the seeds internally in worms, calculous complaints, &c. *Sisymbrium muralis* (*Ditoplaxis muralis*, P. Robert) has been recently used in France in scurvy, scrofula, and other cachectic affections, especially associated, in the form of syrup, with iodide of potassium. (*Ann. de Thérap.*, 1864, p. 126.) W.

SIUM NODIFLORUM. *Water-parsnep.* A perennial, umbelliferous, aquatic European plant, growing also in the southern section of the United States, where it is supposed to have been introduced. It is commonly considered poisonous; but the expressed juice, given by Withering in the dose of three or four ounces every morning, was not found to affect the head, stomach, or bowels. He found it, in this quantity, very advantageous in obstinate cutaneous diseases; and the plant has been usefully employed by others in similar complaints, and in scrofulous swellings of the lymphatic glands. It is considered diuretic. *Sium latifolium*, which grows in Europe and the United States, and is the *common water-parsnep* of this country, is positively asserted to be poisonous; and madness and even death are said to have followed the use of the root. The *S. Sisarum* or *skirret*, a plant of Chinese origin, cultivated in Europe, has a sweetish, somewhat aromatic root, which is employed as food in the form of salad, and is supposed to be a useful diet in complaints of the chest. W.

SMALT. *Azure.* When the impure oxide of cobalt, obtained by roasting the native arseniuret of that metal, is heated with sand and potassa, the mixture melts, and a beautiful blue glass results, which, when reduced to powder, receives the name of smalt or azure. It is used chiefly in painting. W.

SOAP BARK. This is the product of *Quillaya Saponaria*, an evergreen tree, growing in the mountains of Chili, in South America, and known to the inhabitants by the name

of *quillay*, said to be derived from the Chilian word *quillean*, which signifies to wash. It is the liber or inner bark that is employed, the outer dead layers being rejected. When bruised, and macerated in water, it imparts to that liquid the property of frothing like soap, when agitated. This has been found by MM. Fleury jun. and Boutron Chalard to be owing to the existence of *saponin* in the bark, the same principle as that which gives a similar property to *Saponaria officinalis*. The bark contains neither tannic acid nor any bitter principle. It is much used along the western coast of South America, where it constitutes an article of commerce; and we are informed that it is also imported into this country; being employed for cleansing cloth from grease. According to Mr. Charles Raymond, the people of Chili use it in washing silken and woollen stuffs, when it is desirable not to change their colour, and still more for cleansing the hair, which it is supposed to beautify and preserve. On the same authority, it is stated to be sometimes given as a febrifuge, and as a remedy in colds in the head. For the latter purpose, its powder is snuffed up the nostrils. It causes sneezing and profuse nasal discharge. (*Journ. de Pharm.*, xxxii. 220; also *Am. Journ. of Pharm.*, xxix. 104.) W.

SOLUBLE MERCURY OF HAHNEMANN. This is prepared by adding, drop by drop, a dilute solution of ammonia to an equally dilute solution of nitrate of protoxide of mercury, until the precipitate begins to be paler than at first. It is a black powder, which has usually the composition expressed by the formula $NH_4O,3HgO + NO_5$. It is, therefore, an ammoniated nitrate of protoxide of mercury. When it has a gray colour, the fact shows that too much ammonia has been employed in its precipitation. This preparation is included in the French Codex. It has been used in syphilitic diseases. B.

SOOT. *Fuligo Ligni*. This well-known substance has a peculiar smell, and a bitter, empyreumatic, and disagreeable taste. Its composition is very complex. Reduced to powder and treated with water, it affords an infusion of a deep-yellow or brown colour, which is deeper if heat is employed. The insoluble portion amounts to about 44 per cent. The soluble part consists chiefly, according to Berzelius, of a pyrogenous resin united with acetic acid (*acid pyretin*), saturated with potassa, lime, and magnesia. It also contains sulphate of lime, chloride of potassium, acetate of ammonia, and traces of nitric acid. When the solution is evaporated to dryness, it furnishes a black extract. This forms with water a blackish-brown solution, which, when treated with any free acid except the acetic, lets fall the acid pyretin, in the form of a black mass resembling pitch; while the acid employed remains in solution with the bases previously in combination with the pyretin. Braconnot thought he had discovered in pyretin a peculiar principle, which he named *asbolin*; but Berzelius believed he was mistaken. Besides these substances, Braconnot ascertained the existence in soot of an azotized extractive matter to the amount of 20 per cent. This matter, when submitted to dry distillation, affords a considerable proportion of pyrogenous oil. Soot itself, when subjected to a similar distillation, furnishes one-fifth of its weight of empyreumatic oil. To the above ingredients of soot must be added creasote, to the presence of which it is supposed to owe its medicinal properties.

Soot was formerly officinal with the Edinburgh College, and the Scotch physicians were in the habit of frequently prescribing it as a tonic and antispasmodic in the form of tincture. It went very much out of use in regular practice; but came again into vogue after the discovery of creasote, which is one of its ingredients. At present it is chiefly used as an external remedy in the form of decoction or ointment. In the *Revue Méd.* for June, 1834, M. Blaud details a number of cases of various affections, such as obstinate tetters, porrigo favosa, psora, fistula, cancerous and venereal ulcers, chronic irritations of the lining membrane of the mouth, exudations from the mucous membrane of the nose, herpetic eruptions of the genital organs, and pruritus of the vulva, in which the use of soot effected cures. The *decoction* is made by adding two handfuls of soot to a pint of water, boiling for half an hour, and filtering. It is applied as a lotion to the affected parts, or injected into the fistulas several times a day; and, in the intervals, the part, if accessible, is dressed with an *ointment*, made by rubbing up a drachm of finely powdered soot with an ounce of lard. In cases of porrigo, the crusts must be removed by poultices before the soot is applied. In treating obstinate cases of chronic eczema, M. Bougard, of Belgium, has been very successful with the use of a mixture of equal parts of soot and glycerin. In scrofulous ophthalmia, M. Caron Duvillards and M. Baudeloeque have found a collyrium, made according to the following formula, very useful. Infuse two ounces of soot in boiling water, filter the solution, and evaporate it to dryness. Dissolve the dry residue, with the assistance of heat, in strong white wine vinegar, and add extract of roses in the proportion of twenty-four grains to twelve fluidounces of the liquid. It is prepared for use by adding a few drops of the liquid to a glass of water. (*Bull. Gén. de Thérapeutique*, Mars, 1834.) This formula is not very satisfactory; as it does not indicate the proportion of vinegar to be employed. In a case of severe and extensive burn, in which, after the separation of the sloughs, the patient began to sink from the profuse discharge, Dr. Ebers, of Bordeaux, found advantage from the application, to the granulating surface, of lint soaked in a decoction of soot. It reduced the discharge in a surprising manner, and promoted cicatrization.

The late Dr. Hewson, of this city, found an infusion of soot an efficacious remedy, employed by injection, in cases of ascarides. In one case of long standing in an adult, in which a number of remedies had been tried unsuccessfully, injections of soot daily, persevered in

for two weeks, effected a complete cure. The injection was made by adding a cupful of soot to a pint of boiling water, and straining the solution. An *infusion of hickory ashes and soot* is used in this city as a popular remedy for dyspepsia. It is made by infusing a pint of clean hickory ashes and a gill of soot in half a gallon of boiling water, allowing the liquor to stand for twenty-four hours, and then decanting. Of this a small wineglassful is taken three or four times a day. No doubt this infusion has been useful in acidity of stomach; but its indiscriminate use in the various gastric affections, popularly confounded under the name of dyspepsia, is calculated to do much harm. Soot is decidedly antiseptic. A few shovelfuls of it, thrown into privies or drains, effectually destroy their foul exhalations. B.

Dr. E. A. Wood, of McKeesport, Pa., strongly recommends soot as a remedy in uterine hemorrhage, having been induced first to try it by having witnessed its success in a case of the kind, employed as a domestic remedy. He has himself repeatedly used it with success. He prepares the soot for administration by boiling it for an hour in a muslin bag, and of the decoction thus made gives a wineglassful every half hour until the hemorrhage is arrested. (*Med. and Surg. Reporter*, May 11, 1867, p. 401.) W.

SORBUS AUCUPARIA. *Mountain Ash.* A small European tree, of the family of Rosaceæ, distinguished by its pinnate leaves, somewhat resembling that of the ash, and its beautiful clusters of scarlet fruit about as large as peas, which give it a striking appearance, and have caused it to be cultivated in ornamented grounds. We have an American species, *S. Americana*, which is similarly characterized, and is highly ornamental to our mountain regions in autumn and winter by its bright scarlet fruit. The fruit of the European plant, and the same is probably the case with our own, contains a peculiar kind of sugar called *sorbin*, susceptible of the vinous fermentation; and an alcoholic drink has been prepared from it. It seems to have been used for preparing malic acid; and Dr. Hofmann has discovered in it two new acids, which he designates as *sorbic* and *parasorbic acids*. (See *Pharm. Journ.*, May, 1859, p. 573.) It has been used in scurvy, and, in infusion, as a remedy in hemorrhoids and strangury. All parts of the tree are astringent, and may be employed in tanning, and dyeing black. W.

SORGHUM SACCHARATUM. *Sorghum. Chinese Sugar-cane.* This valuable plant, indigenous in India, China, and other parts of the East, has within a few years been introduced into Europe and the United States. It was not till 1851 that the seeds were first sent to France from China; and so late as 1855 only a few acres were cultivated. In 1854 some seeds were brought to the United States by Mr. D. Jay Browne, for the Patent Office, from France, and were distributed to different persons through the country. (*H. S. Olcott.*) The sorghum is now very largely cultivated in this country and in France, and there has probably been no instance in which a plant has more rapidly grown into general favour, as an object of agriculture, than this. Barth, in his Travels in Africa (Am. ed., ii. 339), states that it is extensively cultivated in the interior of that continent. It ranks botanically with the *Graminaceæ*, and belongs to Polygamia Monœcia in the Linnæan system. It is an annual plant, with a jointed stem from eight to fifteen feet or more in height, furnished with alternate, sheathing, ensiform leaves, two or three feet long by about two inches or more in breadth, and ending in a panicle of flowers arranged in spikelets, each composed of from three to five flowers, of which one only is fruitful. The glumes, which envelop the fruit at maturity, are of a deep-brown colour, which is characteristic of the species. The seeds which are about as large as millet seeds, are planted in the spring in rows, like Indian corn, and the plant attains maturity in September or October. It is valued chiefly for the saccharine product of its stems, but other parts also are used. The seeds, though not fitted as food for man, answer well for poultry and domestic animals generally; the leaves, stripped from the stem and dried, make an excellent winter fodder for cattle; and we have been informed that the stems, when deprived of their juice, are sold to the paper-makers. Prof. Hétet, of the Medical School of Toulon, has found in the glumes of the seeds two colouring principles, one *red*, only slightly soluble in water, but readily dissolved by alcohol, ether, and acid and alkaline solutions, the other *yellow*, very soluble in water and the other menstrua mentioned, both of which may be used in dyeing, and might be substituted for madder. (*Journ. de Pharm.*, Avril, 1859, p. 262.) The stem abounds in juice, which becomes more and more saccharine with the growth of the plant. The proportion of juice is 80 or 90 per cent., and of sugar on the average about 7, though it may reach 10 or 15 per cent. (Hétet, *Ibid.*, p. 258.) According to *M. Leplay*, who has been largely concerned in the manufacture of alcohol and sugar from the sorghum, the period at which the stem yields most sugar is when the seeds are quite ripe yet not hardened, and before the stem has lost its green colour. He also determined by his experiments that, though the juice before this period is less rich in proper sugar of cane or crystallizable sugar, which in solution turns the plane of polarization to the right, yet it contains uncrystallizable sugar capable of conversion into alcohol, and may be profitably employed for this purpose. M. Leplay thinks that the whole of the saccharine matter of the juice, when the seeds are perfectly ripe, is crystallizable, and exists in a proportion often exceeding 15 per cent. Another important fact stated by M. Leplay is, that the sorghum stalks, if carefully dried, lose none of their sugar, and may thus be advantageously carried from various points of production to central manufacturing establishments. (*Ibid.*, 3e sér., xxxiii. p. 342.) If these

facts shall be found applicable to the sorghum as cultivated in this country, there is little doubt that the plant will some time be largely employed for the preparation of sugar, should the supply of that from the cane be from any cause insufficient to meet the demand. From experiments by Dr. C. M. Wetherill, the results of which are published in the official U. S. Patent Office Report for 1862 (p. 523), it appears that 17 different specimens of juice, from different parts of the U. States, yielded an average of 4·82 per cent. of crystallizable sugar, 6·46 per cent. of uncrystallizable sugar, and 11·25 per cent. of both kinds. But we are not informed at what period, precisely, in reference to the maturity of the seeds, the juice was expressed; so that there are no grounds of comparison with the results obtained by M. Leplay. At present the sorghum is used almost exclusively in the preparation of molasses, vast quantities of which are made in the United States, sufficient in many instances to meet the wants of the whole neighbourhood. The molasses is prepared by expressing the stems, between rollers, in a machine worked either by the hand, or by horse or steam power, and submitting the juice to ebullition, in order to concentrate it sufficiently, and at the same time coagulate any albuminous matters that may be contained in it. The addition of a little lime to the juice before boiling will prove useful, both by neutralizing acid, which would give a tendency to the saccharine matter to pass into glucose, and by combining with organic principles which interfere with clarification. From what has been above stated, it will be inferred that, when molasses merely is wanted, or when the object is to obtain alcohol or vinegar, it will not be necessary to wait till the seeds are perfectly ripe; and thus a late crop may be made useful, though insufficiently advanced to ripen before frost. For the manufacture of sugar, the stems should not be pressed until the maturity of the fruit.

Another plant, called *imphee* or *African sugar-cane*, has been cultivated to a considerable extent for the same purposes as the sorghum. It is a native of Africa, where it is said to be cultivated by the Kaffirs. Its botanical characters do not seem to be well determined, though considered by Mr. Leonard Wray as a Holcus, and specifically designated as *Holcus saccharatus*. (Olcott, *Sorgho and Imphee*, 6th ed., p. 201.) This, however, as defined by Linnæus, is considered by some botanists as a mere synonyme of *Sorghum saccharatum*; and it is highly probable that the two plants are mere varieties of the same species. The seeds of the imphee were brought to this country in 1856 or 1857, and first planted in South Carolina; but we have not learned how far its cultivation has extended, nor what relative proportion it bears to that of the Chinese plant. Still another variety of sorghum has recently been introduced from the islands of the South Pacific, under the name of *Otaheitan sugar-cane*, and cultivated to some extent in the West. It is distinguished by its long heads, from 7 to 12 inches in length, and from 1 to 2 in thickness. This variety, however, has not yet become generally diffused. (*Patent Office Report*, 1862, p. 515.)

Credit is due to Mr. J. S. Lovering, of Philadelphia, for first demonstrating, in this country, that sugar might be advantageously made from the Chinese sugar-cane; and his pamphlet on the subject will be found useful by those who may purpose to engage practically in its manufacture. W.

SPARTIUM JUNCEUM. *Spanish Broom.* A small shrub, indigenous in the South of Europe, and cultivated in our gardens as an ornamental plant. The flowers are large, yellow, and of an agreeable odour. The seeds are in moderate doses diuretic and tonic, in large doses emetic and cathartic, and have been used advantageously in dropsy. The dose is from ten to fifteen grains three times a day. They may also be given in tincture. W.

SPONGE. *Spongia. Spongia officinalis.* U.S. 1850. This, being no longer recognised in the Pharmacopœias, is transferred to this place from *Part* I. The sponge is now generally admitted to be an animal. It is characterized as "a flexile, fixed, torpid, polymorphous animal, composed either of reticulate fibres, or masses of small spires interwoven together, and clothed with a gelatinous flesh, full of small mouths on its surface, by which it absorbs and ejects water." More than two hundred and fifty species have been described by naturalists, of which several are probably employed, though *Spongia officinalis* is the only one that has been designated in the Pharmacopœias. Sponges inhabit the bottom of the sea, where they are fixed to rocks or other solid bodies; and are most abundant within the tropics. They are collected chiefly in the Mediterranean and Red Seas, and in those of the East and West Indies. In the Grecian Archipelago many persons derive their support altogether from diving for sponges. When collected they are enveloped in a gelatinous coating, which forms part of the animal, and is separated by first rubbing them with fine sand (*Landerer*), and then washing them with water. Large quantities of the coarser kinds are imported from the Bahamas; but the finest and most esteemed are brought from the Mediterranean.

Sponge, as found in commerce, is in yellowish-brown masses of various shapes and sizes, light, porous, elastic, and composed of fine, flexible, tenacious fibres, interwoven in the form of cells and meshes. It usually contains numerous minute fragments of coral or stone, or small shells, from which it must be freed before it can be used for ordinary purposes. Sponge is prepared by macerating it for several days in cold water, beating it in order to break up the concretions which it contains, and dissolving what cannot thus be separated of the calcareous matter by muriatic acid diluted with thirty parts of water. By this pro-

cess it is rendered perfectly soft, and fit for surgical use. It may be bleached by steeping it in water impregnated with sulphurous acid, or by exposure in a moist state to the action of chlorine. When intended for surgical purposes, the softest, finest, and most elastic sponges should be selected; for forming *burnt sponge*, the coarser will answer equally well. According to Mr. Hatchett, the chemical constituents of sponge are gelatin, coagulated albumen, common salt, and carbonate of lime. Magnesia, silica, iron, sulphur, and phosphorus have been detected in it; as also have iodine and bromine, combined with sodium and potassium. From the experiments of Mr. Croockewit, it would appear that sponge is closely analogous to, if not identical with the fibroïn of Mulder, differing from it only in containing iodine, sulphur, and phosphorus. (*Annal. der Chem. und Pharm.*, xlviii. 43.) *Fibroïn* is an animal principle, found by Mulder in the interior of the fibres of silk.

Medical Properties and Uses. Sponge, in its unaltered state, is not employed as a medicine; but, in consequence of its softness, porosity, and property of imbibing liquids, it is very useful in surgical operations. From the same qualities it may be advantageously applied over certain ulcers, the irritating sanies from which it removes by absorption. Compressed upon a bleeding vessel, it is sometimes useful for promoting the coagulation of the blood, especially in hemorrhage from the nostrils. In the shape of *sponge tent* it is employed for dilating sinuses. This is prepared by dipping sponge into melted wax, compressing it between two flat surfaces till the wax hardens, and then cutting it into pieces of a proper form and size. By the heat of the body the wax becomes soft, and the sponge, expanding by the imbibition of moisture, gradually dilates the wound or sinus in which it may be placed. For other modes of preparing sponge tent, as well as of saturating the sponge at the same time with substances calculated to make a remedial impression, as carbolic acid, alum, acetate of lead, &c., see a paper by Dr. Geo. Syng Bryant, of Lexington, Ky., in the *Am. Journ. of Pharm.* (Oct. 1868, p. 410); and for a method of preparation by Dr. J. B. Hough, of Ridgeville, Ohio, see the same journal (Sept. 1869, p. 446; from the *Cincin. Lancet and Observer*, July, 1869). After having been partially charred by heat, sponge has long been used as a remedy in goitre. Its efficacy in this complaint, formerly considered doubtful by many physicians, has been generally admitted since the discovery of iodine.

Spongia Usta. *U. S.* 1850. *Burnt Sponge.* This was an officinal preparation of the U. S. Pharmacopœia. The following was the formula for its preparation. "Take of sponge *a convenient quantity*. Cut it into pieces, and beat it that any extraneous matter may be separated; then burn it in a close iron vessel until it becomes black and friable; lastly, rub it into very fine powder." *U. S.* The sponge is decomposed, the volatile matters being driven off by the heat, and a black friable coal remaining. Preuss found that, of 1000 parts of sponge submitted to calcination, 343·848 were dissipated; and the residue consisted of 327 parts of carbon and insoluble matters, 112·08 of chloride of sodium, 16·43 of sulphate of lime, 21·422 of iodide of sodium, 7·57 of bromide of magnesium, 103·2 of carbonate of lime, 35·0 of phosphate of lime, 4·73 of magnesia, and 28·72 of protoxide of iron. (*Pharm. Cent. Blatt*, 1837, 169.) Herberger found in burnt sponge 1 per cent. of iodide of potassium, and 0·5 per cent. of bromide of potassium. (*Annal. der Pharm.*, xx. 204.) As the remediate value of burnt sponge depends chiefly upon the presence of iodine, it cannot be esteemed good unless it afford purple fumes when acted upon by sulphuric acid assisted by heat. It is said that the preparation is most efficient as a remedy, when the sponge is kept on the fire no longer than is necessary to render it friable. The powder is then of a much lighter colour. Guibourt recommends that the sponge selected for burning should be unwashed, of a strong odour, firm, and compact, that it should be put into a roaster like that used for coffee, and heated over a moderate fire till it becomes of a blackish-brown colour, that it should then be removed, powdered, and enclosed in a well-stopped glass bottle. It is best when recently prepared; as the iodine is dissipated by time, and the specimens, at first richest in this principle, contain little of it at the end of a year. (*Journ. de Chim. Méd.*, Dec. 1831.) According to Herberger, the fine and coarse sponges do not materially differ in the proportion of their organic constituents; so that the coarse may be selected for this operation. Burnt sponge has been highly recommended in goitre, glandular swellings of a scrofulous character, and obstinate cutaneous eruptions. It is most conveniently administered mixed with syrup or honey, in the form of an electuary, with the addition of some aromatic, as powdered cinnamon. The dose is from one to three drachms. W.

STAPHISAGRIA. *Stavesacre.* The seeds of *Delphinium Staphisagria*. This officinal of the late London and Edinburgh Pharmacopœias has been discarded in the British. For the characters of the genus Delphinium, the reader is referred to *Delphinium Consolida*, in *Part* I. *Delphinium Staphisagria*, or stavesacre, is a handsome annual or biennial plant, one or two feet high, with a simple, erect, downy stem, and palmate, five or seven-lobed leaves, supported on hairy footstalks. The flowers are bluish or purple, in terminal racemes, with pedicels twice as long as the flower, and bracteoles inserted at the base of the pedicel. The nectary is four-leaved and shorter than the petals, which are five in number, the uppermost projected backward so as to form a spur, which encloses two spurs of the upper leaflets of the nectary. The seeds are contained in straight, oblong capsules. The plant is a native of the South of Europe. Stavesacre seeds are about as large as a

grain of wheat, irregularly triangular, wrinkled, externally brown, internally whitish and oily. They have a slight but disagreeable odour, and an extremely acrid, bitter, hot, nauseous taste. Their virtues are extracted by water and alcohol. Analyzed by MM. Lassaigne and Feneulle, they yielded a brown and a yellow bitter principle, a volatile oil, a fixed oil, albumen, an azotized substance, a mucilaginous saccharine matter, mineral salts, and a peculiar organic alkali called *delphine* or *delphinia*, which exists in the seeds combined with an excess of malic acid. It is white, pulverulent, inodorous, of a bitter acrid taste, fusible at 150° and becoming hard and brittle upon cooling, volatilizable at 300° (*Gay*), slightly soluble in cold water, very soluble in alcohol and ether, and capable of forming salts with the acids. It is obtained by boiling a decoction of the seeds with magnesia, collecting the precipitate, and treating it with alcohol, which dissolves the *delphinia*, and yields it upon evaporation. According to M. Couerbe, it is impure as thus obtained, consisting of three distinct principles; one of a resinous nature, separated from its solution in diluted sulphuric acid by the addition of nitric acid; another distinguished by its insolubility in ether, and named by M. Couerbe *staphisain;* and the third soluble both in alcohol and ether, and considered as pure delphinia. (*Journ. de Pharm.*, xix. 519.)

Medical Properties and Uses. The seeds were formerly used as an emetic and cathartic, but have been abandoned in consequence of their violence. Powdered and mixed with lard, they are employed in some cutaneous diseases, and to destroy lice in the hair. An infusion in vinegar has been applied to the same purpose. A preparation made by mixing three parts of the seeds in fine powder with five parts of lard, and maintaining the mixture at the temperature of 212° for twenty-four hours, is recommended by Dr. Bourguignon as very efficacious in the itch. (*Journ. de Pharm*, 3e sér., xviii. 421.) M. Bazin has obtained good effects from the external and internal use of stavesacre in eczema. He gave the extract in the dose of a grain and a half from four to twelve times a day. (*Ann de Thérap.*, 1851, p. 18.) Mr. B. Squire, believing that prurigo senilis is essentially the result of the presence of the *pediculus corporis*, is in the habit of treating the affection with an ointment made by incorporating a little wax with the oily matter extracted from stavesacre by ether, which amounts to about one-half of the seeds by weight, and contains all their virtues. In the most obstinate cases, this ointment effectually cures the disease, generally in less than a week. (*Pharm. Journ.*, 2d ser., vi. 405.) A strong tincture has been employed as an embrocation in rheumatism. In some countries the seeds are used to intoxicate fish in the same manner as Cocculus Indicus.

Delphinia is highly poisonous, exerting its effects chiefly on the nervous system. Experiments made by Drs. Falck and Rörig on the lower animals show that, introduced into the rectum, the cellular tissue, or the veins, it produces death by asphyxia, preceded by symptoms of local irritation, convulsive movements, and extreme anæsthesia, without apparent disturbance of the cerebral functions until the moment before death. Introduced into the stomach, it caused salivation, vomiting, and diarrhœa, without other signs of absorption. (*Arch. Gén.*, 4e sér., xxx. 482.) Similar results were subsequently obtained by Dr. Van Praag, who found also that the nerves of motion were paralyzed as well as those of sensation. After death, congestion of the cerebral membranes, heart, great veins, and liver was observed. Dr. Turnbull, in his work "*On the Medical Properties of the Ranunculaceæ*," states that pure delphinia may be given to the extent of three or four grains a day, in doses of half a grain each, without exciting vomiting, and without producing much intestinal irritation, though it sometimes purges. In most instances it proves diuretic, and gives rise to sensations of heat and tingling in various parts of the body. Externally, it acts like veratria; but, according to Dr. Turnbull, produces more redness and burning, and less tingling than that substance. He has employed it in neuralgia, rheumatism, and paralysis. It may be applied by friction, in the form of ointment or alcoholic solution, in proportions varying from ten to thirty grains of the alkaloid to an ounce of the vehicle: and the friction should be continued till a pungent sensation is produced. W.

STERCULIA ACUMINATA. *Cola acuminata*. Daniell. This is a large African tree, known as the source of the *kola nuts* of Guinea. In the last edition of the Dispensatory we announced that Dr. Daniell had just discovered in these nuts a crystallizable alkaloid, which he believed to be *thein*, or as it is now generally called *caffein*. He was induced to make the examination by noticing that, after taking a decoction of the seeds, he was affected with long-continued loss of sleep. Since that time, we have had a more particular account of the nuts from Dr. Daniell, and a detailed analysis by Dr. J. Attfield, which fully confirm the conjecture as to the existence of thein in them. They are extensively used and highly valued throughout a large part of Africa, being chewed for their agreeable effects on the system, and the remarkable property of causing wakefulness. The possession of this property is explained by the presence of caffein in the seeds; and thus another is added to the list of vegetable products, which, having been employed by the natives of the country where they grow, as an agreeable stimulant to the nervous system, have been found to contain caffein. Coffee, tea, Paraguay tea, and guarana or paullinia are the other members of this small class of bodies. (*Pharm. Journ.*, March, 1865, 2d ser., vi. 450.) Dr. Attfield found in 100 parts of the seeds 13·65 of water, 20·00 of cellulose and colouring matter, 41·50 of starch, 1·52 of volatile and fixed oil, 6·33 of an albuminoid substance, 10·67 of gum, sugar, and other organic matter, and 2·13 of thein (caffein); and obtained 2·13 per

cent. of ashes. The nuts contain no tannin, and in this respect differ from coffee, which they otherwise resemble. Dr. Attfield separated the caffein by precipitating a decoction with subacetate of lead, removing the excess of lead by sulphuretted hydrogen, and allowing the clear solution to evaporate to dryness. The residue was treated with hot alcohol, and the alcoholic solution evaporated to a small bulk. On cooling, this solidified into a crystalline mass, which was found to have all the properties of caffein. The kola nut is described as roundish, compressed, resembling the European chestnut, and of a bitter taste. Dr. Daniell informs us that it is used by the white inhabitants on the gold coast with apparent benefit in diarrhœa. (*Am. Journ. of Pharm.*, May, 1865, p. 205; from *Chem. News*, Feb. 17, 1865.) W.

SUCCINIC ACID. *Acidum Succinicum.* This acid is obtained by distilling amber. (See *Succinum.*) The product is an aqueous solution of impure succinic acid, associated with empyreumatic oil. (See *Oleum Succini.*) By filtering the liquor the solution of the impure acid passes through, while the oil is absorbed by the paper. The acid may be purified by boiling the solution with nitric acid, diluted with twice its bulk of water, and then evaporating to crystallize. Should the crystals not be colourless, the treatment with nitric acid must be repeated until they are so. Succinic acid is formed artificially by the action of nitric acid on the fatty acids, and under various other circumstances. M. Desaignes obtained it from malate of lime, subjected to fermentation excited by casein. The malate was converted into succinate of lime, which was then decomposed by sulphuric acid, so as to yield succinic acid. For the details of the process for obtaining succinic acid from malate of lime, see the paper of E. J. Kohl, in the *American Journal of Pharmacy* for July, 1856. Succinic acid, when pure, is a white, transparent solid, crystallizing in prisms, and having a somewhat acrid taste. It dissolves in five times its weight of cold, and twice its weight of boiling water. It is soluble also in alcohol, but very sparingly so in ether. Nitric acid is without action on it. It melts at 365°, and boils without alteration at 473°. It sublimes, however, at a much lower temperature. According to Wackenroder, it is sometimes adulterated with tartaric acid, soaked in oil of amber. Crystallized from its solution in water, its formula is $C_4H_2O_3+HO$. The sublimed acid has the formula $2C_4H_2O_3+HO$. Some chemists double the equivalent of this acid, and make its formula $C_8H_4O_6$.

Succinic acid, though formerly officinal, is at present seldom used in medicine. It has been ascertained to be a product of vital action, having been detected by M. Heintz in the colourless liquid found in hydatid cysts of the liver. (See *Journ. de Pharm.*, Sept. 1850.) One of its salts, *succinate of ammonia*, has been used with great alleged success in delirium tremens. This salt is occasionally used as a precipitant of sesquioxide of iron. B.

SULPHATE OF ALUMINA AND IRON. This double salt was brought forward by Sir James Murray, of Dublin, as an astringent, styptic, and vermifuge. His method of preparing it is not very clearly expressed; but it may be presumed to be formed by dissolving alumina and carbonate of iron, both recently precipitated, in sulphuric acid, and duly evaporating the solution. Sir James recommends it in chronic dysentery, diarrhœa, fluor albus, and the colliquative sweats and diarrhœa which attend hectic fever and consumption. Externally he found it a powerful styptic, useful as a gargle in relaxation of the tonsils and uvula, and in salivation, as an injection in hemorrhages, and as a wash for foul and flabby ulcers. The dose for internal exhibition is from five to ten grains, dissolved in some aromatic water. This salt probably consists of tersulphate of alumina, combined with tersulphate of sesquioxide of iron. It is, therefore, not an alum. B.

SULPHATE OF BARYTA. Barytæ Sulphas. *Ed.*, *Dub.* Having been omitted in the British Pharmacopœia, this salt is no longer officinal; but from its former position, requires a brief notice here. The native sulphate of baryta is used in pharmacy with the same view as the native carbonate; namely, to obtain chloride of barium. The U. S. Pharmacopœia directs for this purpose the carbonate of baryta; but the Ed. and Dub. Colleges gave a separate formula for the use of either the carbonate or sulphate, at the option of the operator. (See *Barii Chloridum.*) Sulphate of baryta is a heavy, lamellar, brittle mineral, varying in sp. gr. from 4·4 to 4·6. It is generally translucent, but sometimes transparent or opaque, and its usual colour is white or flesh-red. When crystallized, it is usually in very flat rhombic prisms. Before the blowpipe it strongly decrepitates, and melts into a white enamel, which, in the course of ten or twelve hours, falls to powder. It is thus partially converted into sulphuret of barium, and, if applied to the tongue, will give a taste like that of putrid eggs, from the formation of sulphuretted hydrogen. It consists of one eq. of acid 40, and one of baryta 76·7=116·7. This salt, on account of its great insolubility, is not poisonous. Ground to fine powder it is sometimes mixed with white lead, but impairs the quality of that pigment. The artificial sulphate of baryta, under the name of *permanent white* or *blanc-fix*, is much used in the arts as a water-colour. It is made from both the native sulphate and carbonate. It forms a dazzling white colour, unalterable by light, heat, air, or sulphuretted hydrogen. It is used by the manufacturers of paper hangings, and for mixing with other colours, the tone of which it does not impair. B.

SULPHATE OF LIME. Calcis Sulphas. *Gypsum. Plaster of Paris.* We notice this salt simply to state that it has recently been introduced into the practice of surgery, as a dressing for fractured limbs, &c. Its origin, general chemical properties, and uses in

the arts are too well known to every chemical student to require exposition here. There are, however, one or two properties which demand notice, as it is upon them that it depends for its adaptation to the surgical use made of it. In the first place, it is so slightly soluble in water, that it may be considered for ordinary purposes insoluble. According to Bucholz, it is soluble in 460 parts of water cold or hot, according to Giese, in 380 parts of cold and 388 of boiling water. Notwithstanding the statement of Bucholz, the fact has been well established, that its solubility varies with the temperature, but, like that of sulphate of soda, very unequally. Thus, according to M. Poggiale, it is greatest at 35° C. (95° F.), and above or below that temperature, gradually diminishes, so that at 100° C. (212° F.), or the boiling point of water, it is very nearly the same as at 5° (41° F.), not far from the freezing point. (*Journ. de Pharm.*, 4e sér., v. 86.) The other point is that, when deprived of its water by heat, and reduced to the state of a white powder, it rapidly absorbs water added to it, and, from the state of semi-liquid paste into which it is brought with that fluid, quickly hardens without change of bulk. It is this property which fits plaster of Paris so well for all kinds of moulding; and to this also it owes its peculiar adaptability to the purpose of a splint. To prepare it for use, the gypsum must first be deprived of the greater part of its water by exposure to a heat of 212° or from that to 250°. One eq. of gypsum contains naturally 2 eqs. of water. Of these at the above temperature it loses one and a half eqs., and what remains, therefore, contains half an eq., with the formula $CaO,SO_3+\frac{1}{2}HO$. Thus dehydrated, it is reduced to fine powder, and kept in air-tight vessels for use. As thus prepared, if mixed with two parts of water, it forms a semi-liquid cream-like mass, which becomes solid and hard in 15 or 20 minutes; the temperature rising during the process, as in the slaking of lime. According to Mr. T. E. Stark, a medical officer in the British army, flannel is the best material for bandages to be used with gypsum. It should be cut into strips an inch and a half broad and two or three yards long, which should first be spread on a table and rubbed well with the powdered gypsum on both sides and always in the direction of the thread. The bandages should then be rolled up loosely, and kept for use in air-tight cases. Thus applied, the bandages, first thoroughly wetted, should be rolled round the limb, overlapping at the edges, so as to make a uniform covering. After application, it should be left to harden, which generally happens in 15 or 20 minutes. For further particulars on this subject, the reader is referred to a paper by Mr. Stark, in the *Medical Times and Gazette* (March, 1865, p. 222). A simpler method of using the gypsum for this purpose is, after the application of the bandages, to paint the whole thoroughly and carefully with the milk of gypsum, which will solidify, and enclose the part in a firm case. W.

SULPHATE OF NICKEL. *Niccoli Sulphas.* This salt is formed by dissolving carbonate of nickel in dilute sulphuric acid, concentrating the solution, and setting it aside to crystallize. The carbonate is procured by dissolving the impure arseniuret of nickel, sold under the name of *speiss*, coarsely powdered and mixed with half its weight of iron filings, in nitromuriatic acid. The solution is evaporated to dryness, and the residue treated with water, which takes up the impure chloride of nickel, and leaves the arsenic in the form of the insoluble arseniate of iron. The liquid is then acidulated with muriatic acid, treated with sulphuretted hydrogen in excess, which precipitates the copper, and, after filtration, boiled with a little nitric acid to sesquioxidize any remaining iron. The cold liquid, largely diluted with water, is next treated with a solution of bicarbonate of soda, gradually added, which throws down the iron in the state of sesquioxide. Lastly, the filtered solution, containing the chloride of nickel nearly pure, is boiled with carbonate of soda, which, by double decomposition, throws down a pale-green precipitate of carbonate of nickel. Sulphate of nickel is in the form of emerald green crystals, efflorescent in the air, soluble in three parts of cold water, but insoluble in alcohol and ether. It has a sweet, astringent taste. When crystallized in rhombic prisms, it consists of one eq. of sulphuric acid 40, one of protoxide of nickel 37·5, and seven of water 63=140·5 (NiO,SO_3+7HO).

Prof. Simpson, of Edinburgh, has made some therapeutic trials with this salt, and found it to act as a gentle tonic, like the preparations of iron and quinia, yet somewhat differently. He used it successfully in a case of severe and obstinate periodic headache. The dose is from half a grain to a grain three times a day, given in the form of pill, or of simple solution. In large doses it is liable to produce nausea and vomiting, especially on an empty stomach. (See *Braithwaite's Retrospect*, xxvii. 446.) Dr. J. D. Palmer, of Monticello, Florida, considers sulphate of nickel as a sedative; having employed it in a variety of painful affections, and also simply as a soporific in cases which did not admit the use of opium, and in every instance with the desired result. (*Am. Journ. of Pharm.*, Nov 1868, p. 516.) B.

SULPHITES, BISULPHITES, HYPOSULPHITES. These salts have, at a comparatively recent date, been introduced into medicine, in reference to their extraordinary hostility, through their acid ingredient, to the lower forms whether of vegetable or animal life. Microscopic plants and animals cannot exist in the presence of sulphurous or hyposulphurous acid; and, as their salts are easily decomposed, with the liberation of the acid, they are capable of exercising the same destructive influence. As it is now generally admitted that a number of our external complaints are caused by these micro-

scopic organisms, the local use of these remedies is often indicated, and, in fact, has been found by experience to be very efficient. Examples of affections of this kind we have in scabies, porrigo, prurigo senilis, different forms of ringworm, pityriasis versicolor, the sore-mouth or thrush of infants, &c.; and in all these complaints benefit may be expected from the local application of these remedies. But a much more extensive use of them has been suggested by a prevalent opinion, first, that the various fermentations have their origin in these invisible organic beings, and, secondly, that a wide circle of diseases, all those, in fact, to which the term zymotic has been applied, are nothing more than the results of different forms of fermentation going on in the human system; such, for example, as cholera, miasmatic fevers, yellow fever, typhus and typhoid fevers, diphtheria, and all the contagious febrile complaints. In these diseases the salts here considered have been prescribed to a considerable extent, and many favourable reports have been made of their effects; but neither the theory on which their employment is based, nor the experience of their practical efficiency, are so thoroughly established as to be admitted, as yet, among the facts of our science.

Of the *sulphites*, those which have been employed are the *sulphites of soda, potassa, ammonia, magnesia*, and *lime*. The *sulphite of soda* is officinal, having been recognised by the U. S. Pharmacopœia, and will be found treated of in the first part of the Dispensatory (*page* 826). The *sulphites* of *potassa and ammonia* may be prepared in the same way; that is, by passing sulphurous acid through a solution of the alkaline carbonate. When the carbonate is insoluble, as in the case of magnesia and lime, it is better to have recourse to the method of double decomposition; but the sulphite of lime may be prepared by using lime-water for the action of the sulphurous acid.

Sulphite of magnesia may be most conveniently prepared by mixing concentrated warm solutions of sulphite of soda and sulphate of magnesia. The sulphite of magnesia, being the least soluble salt that can be formed by an interchange of principles, will be deposited as a crystalline mass, which must be expressed and dried. (J. C. Sticht, *Am. Journ. of Pharm.*, Jan. 1868; from *Wittst. Viertelj.* 1867.) Mr. J. P. Remington, of Brooklyn, N. Y., gives the following method, in which the constituents of the salt are made to act directly on each other. Eight avoirdupois ounces of the best magnesia are thoroughly mixed with a pint of distilled water, and to the mixture the aqueous sulphurous acid of the U. S. Pharmacopœia (sp. gr. 1·035) is added by degrees, with stirring, until the liquid gives a slight acid reaction. The crystals which form are allowed to subside, and, the clear liquid having been decanted, are drained on a muslin strainer, washed with distilled water until free from impurities, and then again drained, and dried on bibulous paper. The product will be about one pound eight ounces of crystals.

In all instances, in the preparation of the sulphites, where evaporation is employed, it should be carefully conducted so as not to drive off the acid, and with as little exposure to the air as possible; as the sulphites in solution are strongly disposed to absorb oxygen, and pass into the state of sulphates. Even in the solid state they slowly undergo the same change, and should therefore be kept, as far as can be conveniently done, excluded from the air.

The sulphites in general have a mild sulphurous taste, and on exposure to heat, or with the addition of an acid, emit the characteristic odour of sulphurous acid. They are distinguishable from the *hyposulphites* by not depositing sulphur on the addition of dilute sulphuric acid to their solution. As the efficiency of the sulphites is ascribable to their acid, they may be used indiscriminately, one being preferred to another according to solubility, or other property affecting the convenience of exhibition. In reference to the individual sulphites it will be necessary to say but little.

Sulphite of soda has been fully described, and the remarks in reference to its therapeutical application may be considered as applicable to the others. (See *page* 827.)

Sulphite of potassa crystallizes in the form of plates or needles, decrepitates when heated, and effloresces in the air, at the same time absorbing oxygen.

Sulphite of ammonia has an acrid sulphurous taste, at first deliquesces in the air, and afterwards dries, having been converted into the sulphate by the absorption of oxygen. It is soluble in its weight of cold, and in less than its weight of boiling water. It decrepitates with heat, losing a part of its ammonia, and then sublimes as a supersulphite.

Sulphite of lime is a white powder, and distinguished by its difficult solubility, requiring 800 parts of water for solution. An excess of acid renders it more soluble; and from its hot saturated solution it is deposited, on the cooling of the liquid, in hexagonal needles.

Sulphite of magnesia, as ordinarily prepared, by double decomposition between a soluble sulphite and a soluble salt of magnesia, is in the form of a white powder, of a stale, earthy taste, with a sulphurous after-taste, less disagreeable than the more soluble salts, and, therefore, sometimes preferred in therapeutics. It is but slightly soluble in water; but is more soluble in liquid sulphurous acid, which, on evaporation, yields transparent crystals. These dissolve in 20 parts of cold water, and effloresce on exposure. When strongly heated in a close vessel, the salt gives up its acid; and magnesia only remains.

The influence of these salts on the system in health is feeble. So far as observation has hitherto gone, they are quite destitute of poisonous properties. Six drachms have been

taken in 24 hours, without any injury whatever. When taken internally, they are absorbed, and partly eliminated unchanged with the urine, partly changed by the absorption of oxygen into sulphates, as happens on exposure out of the body. This is proved by an examination of the urine, which will at first be found to contain a sulphite, and after 24 hours a sulphate. From the largest doses of the sulphites only a laxative operation on the bowels, and an increased secretion of urine, are obtained. For their use in medicine they are solely indebted to the destructive influence they exert over all the lower forms of animal and vegetable life. In reference to this influence they are used both internally and externally; the sulphite of magnesia being usually preferred for the former purpose, the sulphite of soda for the latter. Besides what has been said in this work of their special therapeutic application, the reader is referred, for a full account, to the work of the author on Therapeutics and Pharmacology (3d ed., vol. ii. p. 947). Their long-continued use is said to prove injurious, by inducing debility and anæmia. From fifteen grains to a drachm may be given, so repeated as to amount to from two drachms to an ounce in 24 hours. They may be administered in solution, or, in the case of the sulphite of magnesia, suspended in water, to which sugar and an aromatic tincture may be added. As almost all acids decompose the sulphites, they should not be administered with any acid substance, and no acid should be allowed to exist in the stomach at the time. Should the bowels be disturbed, a little of some opiate may be given. For external use, one part of the salt employed may be dissolved in from five to ten parts of water.

Bisulphites. These are quite as efficient as the sulphites, probably more so, in consequence of their greater proportion of acid. They might be and probably are used indiscriminately with the sulphites; as, in the preparation of the latter by the direct union of their constituents, the sulphurous acid may readily be, and often no doubt is used, in excess, and thus gives rise to the formation of the bisulphite. Indeed, Berzelius states that the salt, formed by passing sulphurous acid through a solution of carbonate of soda until the liquid shall sensibly redden litmus-paper, is really the bisulphite of soda; and that the sulphite may be prepared by adding to this salt a quantity of soda equal to that already contained in it. The bisulphites generally may be prepared by passing sulphurous acid in excess through the alkaline solution, or through the solution of a sulphite already formed. They may be distinguished from the sulphites by being quite neutral to test-paper, while the latter salts have a feeble alkaline reaction. They may be given for the same purposes, and in the same dose and method of administration as the sulphites.

The *bisulphite of lime* has recently assumed a somewhat distinguished position, in consequence of the claims urged in its favour by Mr. W. Lascelles Scott, as an important pharmaceutical agent. In a communication made by him to the "*British Pharmaceutical Conference*," he states, as the result of his experiments, that bisulphite of lime is entirely preservative of oleaginous or fatty substances against spontaneous change; several preparations of this kind having been kept absolutely fresh and sweet by the presence of a little of this salt, for a period of six or seven months, while the same preparations, under otherwise precisely the same circumstances, were quite spoiled. For ointments he has found that a fluidrachm of a strong (probably saturated) solution of this salt is sufficient for their preservation, while it is compatible chemically with the great majority of unctuous matters with which it may be thus associated. Beef tea for use in hospitals may be preserved from injurious change by a few drops of the solution added to each pint; and the same may be said of jellies and other liquid food prepared for use in the sick-chamber. Cloths soaked in the solution, and hung up in a chamber, act as a most efficient disinfectant, while they are free from the unpleasant smell of carbolic acid, or the irritating vapours as well as the offensive odours from the chloride of lime. Mr. Scott has also employed the solution successfully for the preservation of anatomical preparations, and others of an organic nature; being preferable to other agents used for the purpose by exercising no injurious influence whatever on the preparation, and by the entire absence of the poisonous properties of some of these agents, as the mercurials and arsenicals. (*Pharm. Journ.*, Oct. 1867, p. 189.)

Hyposulphites. These may be considered as absolutely identical for therapeutic purposes with the sulphites; as, when they undergo decomposition, it is sulphurous acid which is eliminated. The hyposulphites consist of bases and an acid supposed to consist of two eqs. of sulphur and two of oxygen (S_2O_2), and denominated *hyposulphurous acid*, which, however, exists only in composition, being resolved into sulphurous acid (SO_2) and sulphur when separated. They are prepared by boiling a sulphite or bisulphite in solution with sulphur. If a sulphite is used, the sulphurous acid takes an additional eq. of sulphur, becoming S_3O_2; if a bisulphite, one eq. of sulphurous acid escapes, and the other takes an eq. of sulphur; in either case, the resulting acid remaining combined with the base. The chief advantage possessed by the hyposulphites is that they are less disposed than the sulphites to change into sulphates by the absorption of oxygen. They may be recognised by the deposition of sulphur when an acid is added to their solution. They are freely soluble in water, even the hyposulphites of lime and of magnesia. They may be used for the same purposes and in the same doses as the sulphites, and administered in the same way. W.

SULPHOCARBOLATES. This is a class of salts just introduced into use, as a con-

venient means of obtaining the effects of carbolic acid in the treatment of diseases supposed to have a parasitic origin, as cholera and the so-called zymotic diseases generally. The sulphocarbolates may be readily prepared by heating together pure carbolic and sulphuric acids, diluting the mixture with water, and saturating with the base. Upon evaporation, the sulphocarbolate separates in crystals. A single formula will be sufficient as a guide for all that may be wanted.

Sulphocarbolate of soda is prepared by mixing two measures of pure carbolic acid with one of officinal sulphuric acid in a glass flask; heating the mixture to 280° or 290° F., maintaining the temperature from five to ten minutes; adding, after the liquid has cooled, six or eight measures of water, and carefully neutralizing with carbonate of soda. The solution is then sufficiently evaporated, and set aside to crystallize. The salt is deposited in rhombic prisms, which, when well drained on white filtering paper, and dried by exposure to the air, are pure and colourless.

Sulphocarbolate of magnesia is obtained precisely in the same way, neutralizing with the carbonate of magnesia. This is deposited in white needle-shaped crystals.

Sulphocarbolate of ammonia, prepared in like manner with the substitution of carbonate of ammonia, crystallizes in scales.

Sulphocarbolate of zinc is also formed in the same way, oxide of zinc, added in excess, being the neutralizing agent. This crystallizes in brilliant right rhombic plates, which, also, are colourless when well drained and dried in the air.

All these salts are soluble in water and alcohol. Their solutions are not precipitated by chloride of barium, showing that the sulphuric acid is in some peculiar mode of combination; but, if boiled for several minutes with concentrated nitric acid, they are decomposed; the carbolic acid being converted into picric acid, and deposited on dilution with two measures of water; and the sulphuric acid then giving the ordinary evidence of its presence on the application of the test. Sulphocarbolic acid may be obtained separate in slender needle-shaped crystals. It is analogous to sulphovinic acid, having the formula $C_{12}H_5+SO_3,HO$.

Mr. John Wood has used the sulphocarbolate of zinc, in King's College Hospital, as a dressing for wounds and ulcers, and an injection in gonorrhœa, and, generally, has found it very serviceable in all cases to which carbolic acid is applicable. The strength of the solution employed by Mr. Wood was from three to six grains of the salt to a fluid-ounce of water. (*Pharm. Journ.*, Jan. 1869, p. 428.) W.

SULPHOCYANIDE OF POTASSIUM. *Potassii Sulphocyanidum.* This salt is prepared by fusing in an iron vessel, at a *low* red heat, a mixture of two parts of dried ferrocyanide of potassium, and one part of flowers of sulphur. The mass, when cold, is dissolved in boiling water; and, to decompose some sulphocyanide of iron, the solution is treated with carbonate of potassa, which throws down the iron as a carbonate, and gives rise to the formation of a fresh portion of sulphocyanide of potassium. The whole is then boiled for a quarter of an hour, filtered to separate the precipitated iron, and evaporated that crystals may form. These are purified from carbonate of potassa by being dissolved in alcohol, which takes up the sulphocyanide and leaves the carbonate. The alcoholic solution is then allowed to crystallize. Sulphocyanide of potassium is in long, striated, anhydrous prisms, deliquescent in a moist atmosphere, very soluble in alcohol, and having a cooling, somewhat biting taste. It has been proposed as a medicine by Sömmering, as a substitute for hydrocyanic acid and cyanide of potassium, on the ground that it possesses the same therapeutic properties, without their inconveniences. B.

SULPHURET OF CALCIUM. *Calcii Sulphuretum. Hydrosulphate of Lime.* This compound is formed by passing sulphuretted hydrogen, so long as it is absorbed, through water holding lime in suspension. It is in the form of a paste of a greenish-gray colour, and exhaling a strong odour of sulphuretted hydrogen. It is used as a *depilatory*, and is applied in a layer on the part which is to be deprived of hair. At the end of fifteen minutes it is removed with a wet sponge, which at the same time detaches the hairs. On account of this preparation giving out sulphuretted hydrogen, it must not be applied near the mouth or nose. An impure aqueous solution of sulphuret of calcium, necessarily containing hyposulphite of lime from the manner of its preparation, is used with great success, in Belgium, in itch, the cure of which it effects in a few hours. It is made by boiling together one part of sublimed sulphur, two of lime, and ten of water. The liquid is allowed to cool, and the clear part poured off, and kept in well-stopped bottles. For an explanation of the reaction which takes place, see *Sulphur Præcipitatum*, page 1422. The patient, after having been well washed with soap and tepid water in a bath, is rubbed over with the liquid, which is allowed to dry on the skin for a quarter of an hour. A second bath is then taken, which completes the cure. The preparation, when it dries, leaves on the skin a thin layer of the sulphur compound, which destroys the itch insect and its eggs. B.

SWIETENIA FEBRIFUGA. A large tree growing in the East Indies. The bark is the part employed. It is smooth and red internally, rough and gray on the outer surface, of a feeble aromatic odour, and an astringent bitter taste. Water extracts its virtues by infusion or decoction. It is said to have been much used in India as a substitute

for Peruvian bark, to which it is somewhat analogous in medical properties. The dose of the powder is from thirty grains to half a drachm. The watery extract has the virtues of the bark.

The *Swietenia Mahagoni*, or *mahogany tree*, which grows in the West Indies and other parts of tropical America, has also a bitter astringent bark, which resembles that of S. febrifuga in virtues as well as in sensible properties. The wood of this tree is the mahogany so much used in ornamental wood-work. The bark of *S. Senegalensis* is used on the coast of Africa in the cure of intermittents; and M. Caventou has extracted an alkaloid from it, which has been suggested as a cheap substitute for quinia. (See *Am. Journ. of Med. Sci.*, N. S., xx. 168.) W.

SYMPHYTUM OFFICINALE. *Comfrey.* A perennial European plant, cultivated in our gardens for medical use. Its root, which is the part used, is spindle-shaped, branched, often more than an inch thick and a foot long, externally smooth and blackish, internally white, fleshy, and juicy. By drying it becomes wrinkled, of a firm horny consistence, and of a dark colour within. It is almost inodorous, and has a mucilaginous, feebly astringent taste. Among its constituents are mucilage in great abundance, and a small quantity of tannin. It was formerly highly esteemed as a vulnerary, but has lost its credit in this respect. Its virtues are chiefly those of a demulcent, and it may be advantageously used for all the purposes to which the marshmallow is applied. It is a very common ingredient in the domestic cough mixtures, employed in chronic catarrh, consumption, and other pectoral affections. The most convenient form of administration is that of decoction, which may be made either from the fresh or dried root. According to Lewis, comfrey root yields to water a larger proportion of mucilage than the root of Althæa. W.

SYRINGA VULGARIS. *Common Lilac.* The leaves and fruit of this common garden plant have a bitter and somewhat acrid taste, and have been used as a tonic and febrifuge. In some parts of France, they are said to be employed habitually by the country people in the cure of intermittent fever; and they were recommended by Cruveilhier in the treatment of that complaint. The fruit was examined by MM. Petroz and Robinet, who found a sweet and a bitter principle. The latter was afterwards obtained pure by M. Meillet, who gave it the name of *lilacin*. The green capsules, which yield it in largest proportion, are boiled in water, the decoction is concentrated, subacetate of lead is added, the liquor is evaporated to the consistence of syrup, magnesia is added in excess, and the whole is evaporated to dryness. The residuum is powdered, digested in water at 90° or 100°, and then treated with boiling alcohol and animal charcoal. The alcoholic solution, being filtered and concentrated, yields lilacin upon cooling. This principle, though not alkaline, is thought by M. Meillet to exist in the fruit combined with malic acid. It is crystallizable, bitter, and insoluble in water. (*Am. Journ. of Pharm.*, xiv. 139; from *Journ. de Pharm.*) W.

TACAMAHAC. *Tacamahaca.* The resinous substance, commonly known by this name, is supposed to be derived from the *Fagara octandra* of Linn. (*Elaphrium tomentosum*, Jacq., *Amyris tomentosa*, Spreng.), a tree of considerable size, growing in the island of Curaçoa, and in Venezuela. The juice exudes spontaneously, and hardens on exposure. As brought into the market, it is in irregularly shaped pieces of various sizes, some not larger than a mustard seed, others as much as an inch or two inches in diameter. The colour is usually light-yellowish or reddish-brown; but in the larger masses is more or less diversified. The pieces are in general translucent, though frequently covered with powder upon their surface, so as to render them apparently opaque. They are heavier than water, brittle, and pulverizable, yielding a pale-yellow powder. Their odour is resinous and agreeable, their taste bitter, balsamic, and somewhat acrid. Exposed to heat they melt and exhale a stronger odour. Tacamahac is partially soluble in alcohol, and completely so in ether and the fixed oils. It consists of resin with a little volatile oil.

Another variety is obtained from the East Indies, and called *tacamahaca orientale*, or *tacamahaca in testis*. It is supposed to be derived from the *Calophyllum Inophyllum*, and comes into the market in gourd-shells covered with rush leaves. It is of a pale-yellow colour inclining to green, slightly translucent, soft, and adhesive, of an agreeable odour, and an aromatic bitterish taste. It is at present very rare in commerce. The tree which yields this resin produces a drupe, about as large as a plum, from the seeds of which 50 per cent. of a greenish-yellow fixed oil is obtained by expression, used in India for lamps, and as a local application in the itch. (*Journ. de Pharm.*, Juillet, 1861, p. 23.)

Guibourt describes several other varieties of tacamahac, which, however, are little known. Among them is a soft, adhesive, dark-green resin, said to be procured from the *Calophyllum Tacamahaca*, growing in the islands of Bourbon and Madagascar.

Tacamahac was formerly highly esteemed as an internal remedy, but is now employed medicinally only in the composition of ointments and plasters, and little even for this purpose. Its properties are analogous to those of the turpentines. It is sometimes used as incense. W.

TANNATE OF ALUMINA. *Aluminæ Tannas.* Mr. Rogers Harrison, of London, has employed an aqueous solution of a substance which he calls by this name, as an in-

jection in gonorrhœa, after the acute symptoms have passed. He makes it of such a strength as to produce smarting. The substance is described to be in crystals, about the size of those of coarse sugar, of a dirty-yellowish colour, and readily soluble in hot water. (*Lond. Med. Gaz.*, xiii. 853.) It is not easy to conjecture what is the substance employed by Mr. Harrison. Tannate of alumina is nearly insoluble in water. Prof. Procter tried to make a soluble tannate of this earth, but without success; and, from the description of the substance used by Mr. Harrison, he is inclined to think that it was a mixture of tannic acid and alum. (*Am. Journ. of Pharm.*, Jan. 1853, p. 25.) B.

TANNATE OF IRON. *Ferri Tannas.* This salt is prepared by dissolving 44 parts of precipitated subcarbonate of iron, moderately dried, in a boiling solution of 9 parts of pure tannic acid, evaporating the solution at the temperature of 176°, in a porcelain vessel, until it becomes thick, pouring it out on a glass or porcelain plate, and drying it with a gentle heat. As thus obtained, tannate of iron is in flat pieces, of a crimson colour, without taste, and insoluble in water. It acts as an astringent and tonic, and may be given in chlorosis, in the dose of from eight to thirty grains, in the course of a day, made into pills. *Ink* is an aqueous solution of the tanno-gallate of iron, and probably possesses similar medical properties. It is a popular application to ringworm. B.

TANNATE OF LEAD. *Plumbi Tannas.* This is obtained by precipitating a concentrated infusion of oak bark with acetate of lead, added drop by drop. It has been used as an external application with success by Dr. Fantonetti in two cases of white swelling of the knee-joint. He employed it at first mixed with a third of its weight of lard, and afterwards pure, the fresh precipitate admitting of application as an ointment. Autenrieth recommends it as a dressing to gangrenous ulcers; and it is probably peculiarly efficacious in bed-sores. With this intention, the precipitate, either uncombined, or mixed in its dry state with simple ointment in the proportion of two drachms to the ounce, may be spread on linen, and applied to the sore. Van den Corput uses it in excoriations, applying it freshly precipitated, and rubbed up with glycerin. (*Ann. de Thérap.*, 1865 p. 266.) The preparation here described is a bitannate. Other tannates of lead exist. B.

TARTRATE OF SODA. *Sodæ Tartras.* This salt, in crystals, has been recommended by M. Delioux as an agreeable purgative, almost without taste, and acting with power equal to that of the sulphate of magnesia, in the dose of ten drachms. The *soda powders*, so much used in the United States, form an extemporaneous tartrate of soda, somewhat aërated with carbonic acid. (See *page* 1363.) B.

TAXUS BACCATA. *Common European Yew Tree.* This handsome and well-known evergreen is introduced here, merely to state that a case has recently occurred, in which fatal poisoning took place from the swallowing of its fruit. The patient was a child, who was found in a dying state in a field, where, as proved by the contents of the stomach, he had been eating the berries of the yew. He was found semi-comatose, with convulsions, a cold and clammy skin, difficult respiration, dilated pupils, and attempts at vomiting. He died before anything else could be done than to administer an emetic, which acted promptly. Other children had eaten the same fruit without serious consequences; but they had swallowed the pulp only, rejecting the stones; while these, in a masticated state, were found in the stomach of the deceased child; so that the poisonous property would seem to reside in the stone of the fruit; as in the peach and bitter almond. A horse, having eaten some of the fruit, died in an hour. In the child, death did not take place under four hours. (Dr. James Thompson, *Lancet*, Oct. 17, 1868, p. 530.) W.

TEA. The plant which furnishes tea—*Thea Chinensis*—is an evergreen shrub, belonging to the class and order Monadelphia Polyandria of the sexual system (Polyandria Monogynia, *Linn.*), and to the natural order Ternstromiaceæ. It is usually from four to eight feet high, though capable, in a favourable situation, of attaining the height of thirty feet. It has numerous alternate branches, furnished with elliptical-oblong or lanceolate, pointed leaves, which are serrate except at the base, smooth on both sides, green, shining, marked with one rib and many transverse veins, and supported alternately upon short footstalks. They are two or three inches long, and from half an inch to an inch in breadth. The flowers are either solitary, or supported, two or three together, at the axils of the leaves. They are of considerable size, not unlike those of the myrtle in appearance, consisting of a short green calyx with five or six lobes, of a corolla with from four to nine large unequal snow-white petals, of numerous stamens with yellow anthers and connected at their base, and of a pistil with a three-parted style. The fruit is a three-celled and three-seeded capsule. It has not been certainly determined whether more than one species of the tea-plant exists. Linnæus admitted two species—*T. Bohea* and *T. viridis*—differing in the number of their petals; but this ground of distinction is untenable, as the petals are known to vary very much in the same plant. Hayne makes three species—*T. stricta*, *T. Bohea*, and *T. viridis*—which are distinguished severally by the shape of their leaves and fruit, and the direction of the footstalk. De Candolle admits but one species, with two varieties—the *viridis* or green tea, with "lanceolate flat leaves, three times as long as they are broad," and the *Bohea*, with "elliptical-oblong, subrugose leaves, twice as long as broad." Lindley recognises the two Linnæan species, distinguishing them by the leaves, which in *T. viridis* are acuminate, and emarginate at the apex, and

in *T. Bohea* are smaller, flatter, darker green, with small serratures, and terminate gradually in a point, but are not at all acuminate or emarginate. (*Flora Medica*, 120.)

The tea-plant is a native of China and Japan, and is cultivated in both countries, but most abundantly in the former. In Japan it forms hedgerows around the rice and corn-fields; in China, whence immense quantities of tea are exported, whole fields are devoted to its culture. It is propagated from the seeds, which are planted in holes at certain distances, six or eight seeds being placed in each hole, in order to ensure the growth of one. In three years the plant yields leaves for collection, and in six attains the height of a man. When from seven to ten years old it is cut down, in order that the numerous shoots which issue from the stump may afford a larger product of leaves. These are picked separately by the hand. Three harvests, according to Kœmpfer, are usually made during the year; the first at the end of February, the second at the beginning of April, and the third in June. As the youngest leaves are the best, the product of the first collection is most valuable, while that of the third, consisting of the oldest leaves, is comparatively little esteemed. Sometimes only one or two harvests are made; but care is always taken to assort the leaves according to their age; and thus originate numerous commercial varieties of tea. The character of the plant, dependent upon the soil, situation, climate, and culture, has also a great influence upon the value of the leaves. It is said that the best tea is procured from the shrubs which grow upon the sides of steep hills with a southern exposure. Though the plant grows both about Pekin in the north and Canton in the south of China, it is said to attain greater perfection in the intermediate country, in the neighbourhood of Nankin, for instance, where the climate is neither so cold as in the first-mentioned vicinity, nor so hot as in the second. Some of the commercial varieties have their origin in this cause; and it is highly probable, though the fact has not been certainly proved, that difference in species may be another source of diversity. After having been gathered, the leaves are dried by artificial heat in shallow iron pans, from which they are removed while still hot, and rolled with the fingers, or in the palm of the hand, so as to be brought into the form in which they are found in commerce. The odour of the tea leaves themselves is very slight; and it is customary to mix with them the flowers of certain aromatic plants, as those of the orange, different species of jasmine, the rose, *Olea fragrans*, and *Camellia Sasanqua*, in order to render them pleasant to the smell. The flowers are afterwards separated by sifting or otherwise. (See *Pharm. Journ.*, xv. 112.) The cultivation of tea has been successfully introduced into Brazil, and into the British possessions in India. In 1861, about 20,000 acres of land were under cultivation in Assam, and are said to have yielded 1,705,130 pounds of tea in that year. (*Galignani's Messenger*, Jan. 20th, 1862; from the *London Times*.) Mrs. Ida Pfeiffer states, in her "*Second Journey round the World*" (Am. ed., 1857, p. 127), that tea cultivated in Java is occasionally sent to Europe. Attempts have been made, under the auspices of the Government, to introduce the tea culture into the U. States. Large numbers of the seeds were, through arrangements made by the Patent Office, imported from China, and, having been planted in the propagating garden at Washington, germinated satisfactorily. At the time of publication of the Patent Office report, in 1859, the young plants continued to flourish, and there was every reason to hope that the experiment would eventuate successfully; but nothing, so far as we know, has yet come of it.

Tea is brought to this country from Canton and other ports of China. Numerous varieties exist in commerce, differing in the shape communicated by rolling, in colour, in flavour, or in strength; but they may all be arranged in the two divisions of *green* and *black teas*, which, at least in their extremes, differ so much in properties, that it is difficult to conceive that they are derived from the same species.

Properties. *Green tea* is characterized by a dark-green colour, sometimes inclining more or less to blue or brown. It has a peculiar, refreshing, somewhat aromatic odour, and an astringent, slightly pungent, and agreeably bitterish taste. Its infusion has a pale greenish-yellow colour, with the odour and taste of the leaves. According to Mr. Warington, who examined numerous varieties of tea carefully both by the microscope and chemical tests, many of the green teas imported into great Britain owe their colour to a powdery coating, consisting of sulphate of lime and Prussian blue; others to a mixture of these with a yellowish vegetable substance; and others, again, to sulphate of lime alone. (*Pharm. Journ.*, iv. 37.) *Black tea* is distinguished by a dark-brown colour. It is usually less firmly rolled, and lighter than the green, and contains the petioles of the plant mingled with the leaves. Its odour is fainter, and of a somewhat different character, though still fragrant. Its taste, like that of green tea, is astringent and bitterish; but is less pungent, and to many persons less agreeable. To hot water it imparts a brown colour, with its sensible properties of taste and smell. These vary exceedingly in degree in the different varieties; and some black teas are almost wholly destitute of aromatic or agreeable flavour. According to Mr. Warington, the difference between green and black tea, in reference to their chemical and physical condition, arises from a kind of fermentation which the latter is made to undergo, before being roasted. (*Ibid.*, x. 618.) A sophisticated tea is largely exported from China, consisting of powdered tea mixed with sand and other earth, and agglutinated with gum; that which is to pass for black being coloured with plumbago, and the green with the coating above referred to. On analysis, these teas were found to afford

from 35 to 45 per cent. of ashes, while the genuine yields only 5 per cent. They may be detected by not unfolding when steeped in boiling water. (*Ibid.*)

Analyzed by G. J. Mulder, 100 parts of green Chinese tea afforded 0·79 of volatile oil, 2·22 of chlorophyll, 0·28 of wax, 2·22 of resin, 8·56 of gum, 17·80 of tannic acid of the variety contained in galls, 0·43 of thein (caffein), 22·80 of extractive, traces of apotheme, 23·60 of muriatic extract, 3·00 of albumen, 17·68 of lignin, and 5·56 of salts. The muriatic extract was the matter taken up by diluted muriatic acid from tea, previously exhausted successively by ether, alcohol, and water, and consisted of artificial tannin. The same chemist obtained from 100 parts of black Chinese tea 0·60 of volatile oil, 1·84 of chlorophyll, 3·64 of resin, 7·28 of gum, 12·88 of tannic acid, 0·46 of thein (caffein), 19·88 of extractive, 1·48 of apotheme, 19·12 of muriatic extract, 2·80 of albumen, 28·32 of lignin, and 5·24 of salts. (*Annal. der Pharm.*, xxviii. 317.) Dr. Rochleder has found also a peculiar acid, which he calls *boheic acid*. According to Stenhouse, the tannin of tea, though always accompanied with a little gallic acid, differs essentially from that of galls; not being like it a glucoside, but yielding, under the influence of sulphuric acid, a dark-brown substance, almost insoluble in water. (See *Am. Journ. of Pharm.*, May, 1862, p. 254.) M. Eug. Peligot obtained a much larger proportion of thein or caffein than was found by Mulder, the lowest quantity from green tea being 2·4 per cent. and the highest 4·1 per cent.; but even this quantity is too small to represent all the nitrogen contained in tea. (*Journ. de Pharm.*, 3e sér., iv. 224.) M. Puccetti found about twice as much in black as in green tea. (*Am. Journ. of Pharm.*, xxviii. 234.) The volatile oil is probably one of the principles upon which the effects of tea upon the nervous system depend. Hence old teas are less energetic than those recently imported: and it is said that the fresh leaves have often produced dangerous effects in China. Nevertheless, the tannic acid is not without influence upon the system; and it is not improbable that both the extractive and thein contribute to the peculiar influence of this valuable product. Of these active ingredients, the volatile oil, tannic acid, and extractive are found most largely, according to the analysis of Mulder, in the green tea. *Thein* is a crystallizable principle discovered by Oudry. It was afterwards proved by Jobst to have the same composition as caffein, and is now generally considered as in all respects identical with that principle. It exists also in the leaves of the Ilex Paraguaiensis or Paraguay tea, in the seeds of Paullinia sorbilis, and in the kola nut or fruit of Cola acuminata. (See *Coffee*, *Ilex*, *Paullinia*, and *Sterculia acuminata*.) According to Mulder, thein exists in tea combined with tannic acid. Peligot obtained it by adding to a hot infusion of tea, first subacetate of lead, and then ammonia, filtering the liquid, passing sulphuretted hydrogen through it, again filtering, and evaporating with a moderate heat. On cooling, the liquid deposited thein abundantly, and yielded an additional quantity by a careful evaporation. (*Journ. de Pharm.*, 3e sér., iv. 224.) It may be cheaply prepared by putting some old spoiled tea in an iron pot covered with filtering paper, enclosing the whole in a cylindrical paper cap, and cautiously applying heat. Thein rises in vapour, and condenses on the paper. (See *Chem. Gaz.*, No. 178, p. 119.) Thein has a feebly bitter taste; is, in the state of crystals, dissolved by 93 parts of water, 158 of alcohol, and 298 of ether; melts at about 350° F., and at 723° sublimes in white vapours, which condense in minute needles. From its watery solution few reagents precipitate it. Infusion of galls causes a deposit of tannate of thein, which is again, however, dissolved by heating the water.

Medical Properties and Uses. Tea is astringent and gently excitant, and in its finer varieties exerts a decided influence over the nervous system, evinced by the feelings of comfort and even exhilaration which it produces, and the unnatural wakefulness to which it gives rise, when taken in unusual quantities, or by those unaccustomed to its use. Its properties, however, are not of so decided a character as to render it capable of very extensive application as a medicine; and its almost exclusive use is as a grateful beverage at the evening and morning meals. Taken moderately, and by healthy individuals, it may be considered as perfectly harmless; but long continued, in excessive quantity, it is capable of inducing unpleasant nervous and dyspeptic symptoms, the necessary consequences of over-excitement of the brain and stomach. Green tea is decidedly more injurious in these respects than black, and should be avoided by dyspeptic individuals, and by those whose nervous systems are peculiarly excitable. As a medicine, tea may sometimes be given advantageously in diarrhœa; and a strong infusion will often be found to relieve nervous headache. The mode of preparing it for use is too well known to require description. An extract is made from it in China, which is said to be useful in fevers. Though the effects of tea and coffee upon the system are probably in part owing to the thein or caffein they contain, there must be some other active ingredient; as the effects produced by different varieties are not proportionate to the amount of that principle contained in them. Thus coffee, which exerts a more powerful influence on the system than tea, in any of its varieties, contains less caffein.

Experiments have been made with thein, which go to show that it is a powerful nervous stimulant, very analogous to tea in its mode of action. Prof. H. J. Pratt, of Harvard College, tried it on himself and others, administering it both by subcutaneous injection and by the mouth. He also tried its effects on toads. From quantities less than five grains no very marked effects were obtained, except a slight diminution in the frequency of the pulse and subsequent wakefulness. In a man to whom he gave six grains

subcutaneously, the pulse in fifteen minutes fell from 84 to 68 in the minute, and continued at about the same rate at the end of fourteen hours. The rate of 84 was probably the result of the temporary excitement from the operation; and, so far as this experiment goes, little can be inferred as to the effect on the circulation. Increased frequency of micturition was also noticed. From twelve grains taken by himself by the mouth, he experienced at the end of about two hours great physical restlessness with mental uneasiness, and soon afterwards marked tremulousness of the hands and arms. This continued for about two hours, after which there were no other phenomena except wakefulness, with the "mind in a state of most active and persistent thinking." Similar results took place in other cases; and in one there was what was described "as increased brain power, enabling the patient to read, with great ease and perfect understanding, books before considered abstruse;" a strong evidence of power in theïn to stimulate the nervous system. In relation to the pulse, it was reduced in one instance from 66 to 56, and in another from 76 to 67. The discharge of urine was increased in frequency and amount. In his experiments on toads performed in connection with Mr. Fred. Ware, the subcutaneous injection of theïn produced convulsions, which were ascribed to increased reflex action of the spinal cord. (*Bost. Med. and Surg. Journ.*, Sept. 10, 1868, p. 81.) M. Leven, who experimented comparatively on caffein and theïn, found that, though admitted by chemists to be identical, they differed somewhat in their physiological action. Both increase the frequency of the pulse and of respiration; both stimulate the brain and spinal cord, and, through their action on the cord, induced tetanic convulsions when largely given to the lower animals; and both agree in not abolishing the muscular function, and in not causing the heart to cease contracting immediately after death. But theïn is much less powerful as a poison than caffein, requiring to be given in twice the quantity to produce the same effect; and theïn produces convulsions of the limbs, which Dr. Leven had not noticed as an effect of caffein. (*Am. Journ. of Med. Sci.*, April, 1868, p. 525, and Oct. 1868, p. 260; from *Arch. de Physiol. Norm. et Pathol.*) For the therapeutical use of theïn considered as identical with caffein, see *Part* I. p. 189. W.

TELLURIUM. Several of the combinations of this metal have been tried on the living organism by M. Hansen. Five grains of the *tellurite of potassa*, given to dogs, produced stupefaction and vomiting, and the garlic-like odour of tellurium in the breath. The same salt, tried upon himself for seven successive days, in a dose daily of half a grain, afterwards increased to a grain, caused drowsiness at first, followed, after the seventh day, by a sense of oppression in the cardiac region, nausea, an increased flow of saliva, and loss of appetite. The breath had a garlic-like odour throughout the experiment. (*Chem. Gaz.*, March 1, 1854, p. 90.) Prof. Simpson, of Edinburgh, relates the case of a student, who inadvertently took a dose of tellurium, and exhaled so persistent an odour that he had to sit apart from his fellow students. (See *Am. Journ. of Med. Sci.*, April, 1855, p. 496.) This disagreeable effect of tellurium precludes its employment in medicine. B.

TEPHROSIA VIRGINIANA. *Turkey Pea. Goat's Rue.* Several species of Tephrosia are employed in different parts of the world, though unknown in general commerce. They are leguminous plants, shrubby or herbaceous, with leaves unequally pinnate, and flowers in axillary or terminal racemes. They are generally possessed of cathartic properties; their leaves or roots being employed. *Tephrosia Virginiana* grows in most parts of the United States. It is a foot or two high, with pubescent stems and leaves, and handsome terminal flowers. (See Griffith's *Med. Bot.*, p. 237.) The roots, which are slender, long, and matted, are tonic and aperient, and are said to have been used by the Indians as a vermifuge, given in the form of decoction. Dr. B. O. Jones, of Atlanta, Geo., has used the plant with advantage, as a mild stimulating tonic and laxative, having a tendency to increase most of the secretions, and has found it specially useful in typhoid fever. He prepares it by boiling eight ounces of the plant with two ounces of *Rumex acutus* in four quarts of water to a quart, and straining; adding, when the preparation is to be kept, an equal bulk of diluted alcohol or brandy, and half its weight of sugar; and macerating for several days. The dose is one or two tablespoonfuls. (*Am. Journ. of Pharm.*, xxviii. 218.) W.

TEUCRIUM CHAMÆDRYS. *Germander. Chamædrys.* A small, didynamous, labiate, perennial European plant, the leaves and tops of which have an agreeable aromatic odour, diminished by drying, and a bitter, somewhat astringent, aromatic, durable taste. They have been employed as a mild corroborant, in uterine, rheumatic, gouty, and scrofulous affections, and intermittent fevers; but are at present little used, and never in this country. Germander was an ingredient in the *Portland powder*, noted as a remedy in gout. This powder, according to the original prescription, consisted of equal parts of the roots of *Aristolochia rotunda* and *Gentiana lutea*, of the tops and leaves of *Teucrium Chamædrys* and *Erythræa Centaurium*, and of the leaves of *Ajuga Chamæpytis*, or *ground pine*. The dose was a drachm every morning before breakfast, for three months, then two scruples for three months, afterwards half a drachm for six months, and finally half a drachm every other day for a year. (*Parr.*) Two other species of Teucrium have been used in medicine;—*T. Marum*, *cat thyme*, or *Syrian herb mastich*, indigenous in the South of Europe, and *T. Scordium*, or *water germander*, growing in the higher latitudes of the

same continent. The former is a warm, stimulating, aromatic bitter, and has been recommended in hysteria, amenorrhœa, and nervous debility; the latter has the odour of garlic, and a bitter, somewhat pungent taste, and was formerly highly esteemed as a corroborant in low forms of disease; but neither of them is now much employed. *T. Marum*, however, has been revived somewhat of late; having been given successfully, by Dr. Lucanus, in pertussis and other cases of spasmodic cough, in the forms of syrup and confection. (*Revue Pharmaceut.*, 1858, p. 32.) This species also acts as an errhine, and was formerly an ingredient of the *Pulvis Asari Compositus*. The dose of either of the three species is about half a drachm. A plant said to have been used advantageously in cholera in the Levant, a specimen of which was sent to Paris, proved to be *Teucrium Polium*. (*Journ. de Pharm.*, xv. 352.) W.

THALLIUM. This is one of the metals recently discovered by means of the spectrum analysis, and has been found to prevail widely in nature, and to yield itself readily to chemical agencies. The point about it principally interesting to the physician at present is, that it has been ascertained to act energetically as a poison. M. Lamy, having experienced, while making chemical investigations in reference to thallium, extreme general lassitude, with pains in the lower extremities, was disposed to consider these symptoms as the result of a poisonous influence of the metal. To determine the point, he dissolved 75 grains of sulphate of thallium in some milk, intending to try its effects on a couple of puppies, which, however, after tasting it, refused to swallow more. Accidentally it was placed where other animals had access to it; and the consequences were that the milk disappeared, and a middle-sized dog, a hen, and six ducks died from having drank it. There was no vomiting or purging, but violent intestinal pains, and spasm of the posterior limbs, followed by paralysis; and this last seemed to be the most characteristic effect of the poison. Death took place in two or three days; and, what is of much importance, the two puppies which had only tasted of the milk, were seized with similar symptoms, and died at the end of four days. The poison, therefore, must be very energetic; and a circumstance worthy of remark in relation to it is, that, even in a fatal dose, it may produce no sensible effect for a considerable time. M. Lamy afterwards gave about a grain and a half to a puppy, which died in forty hours. There seems to be a remarkable coincidence between the poisonous effects of thallium and those of lead. Connected with its deleterious action, it is an interesting circumstance that thallium is not unfrequently associated with metals used in medicine, as with copper and bismuth for example. Spectrum analysis affords an easy method of detecting the poison. M. Lamy readily recognised it in the tissues of animals which perished with it, by subjecting small pieces to examination in the spectroscope. A sharply defined green line in the spectrum gave undoubted evidence of the presence of the poison. (*Journ. de Pharm.*, Oct. 1863, p. 285.) The effects of thallium on the system have recently been carefully investigated by Dr. Wm. Marmé, by experiments on different orders of animals, with the following results. Small doses of the different preparations are tolerated for a short time, but the effects are cumulative; and perseverance with their use gives rise to very serious consequences; as the system does not become accustomed to the poison. After continued administration of the preparations of thallium, the appetite is impaired, pain is felt in the bowels, and vomiting occurs, with diarrhœa, hemorrhage, salivation, and emaciation. General debility, embarrassed respiration, weakness of the circulation, disordered muscular action, as tremors and want of co-ordination, are added to the other symptoms; and, when the poisoning becomes general, conjunctivitis, with free secretion of mucus, is a frequent symptom. After death, small effusions of blood and infiltration of the lungs are observed, as are also intense congestion of the bowels, copious pericardial effusion, and ecchymoses on the heart's surface. The poison is absorbed, and is eliminated by all the secretions. It seems to disorganize the blood. There is no known antidote. (*B. and F. Medico-chir. Rev.*, Jan. 1868, p. 254.) W.

THAPSIA GARGANICA. An umbelliferous plant, growing in Southeastern Europe, and well known to the ancients, who named it from the isle of *Thapsos*, where it was obtained. Theophrastus speaks of its root as emetic and purgative. After long neglect, it has again come into notice in France, where a resinous substance derived from it has of late been in much esteem as a local irritant and revulsive, under the name of *resin of thapsia*. (*Ann. de Thérap.*, 1868, p. 210.) The bark of the root and the resin are both objects of commerce. The bark is described by M. Stanis. Martin, as almost always doubly quilled, unless where altogether in small fragments, exteriorly rugose with the epidermis here and there detached in patches larger or smaller, and of a deep-brown colour, interiorly smooth and whitish, and of a fibrous fracture. The size of the pieces varies extremely; the largest not exceeding 24 inches in length and about an inch in circumference. At the point where the root begins there is often adherent a ligneous fibre about an inch long; and over their whole surface there are found but few radicles. It is said that great care is necessary, in removing the root from the bales, not to be injured by the powder which escapes, and which causes itching and swellings of the face and hands. An extract of the *root*, which is sold as a *resin*, has really little claim to be so named; as, of 15 parts of it, 6 are dissolved by cold water, and the 9 parts of resinous matter which remain are of a deep-brown colour, while the resin extracted by sulphuret of car-

bon is of a fine yellow. (*Ibid.* 1869, p. 221; from *Bulletin Thérapeutique.*) M. Cazenave objects to the plaster prepared from the resin, and kept in masses; as it deteriorates by time. He proposes the following method of preparing a plaster extemporaneously when wanted. Dissolve the resin in alcohol, and with the aid of a brush spread it on a suitable recipient, which may be ordinary plaster, waxed taffetas, or simply gummed paper. A single layer is sufficient for the purpose of an active revulsion; but the effect may be increased at pleasure, by increasing the number of layers. (*Journ. de Pharm.*, Juillet, 1868, p. 29.) W.

THLAPSUS BURSA PASTORIS. *Shepherd's Purse.* Thlapsus is a genus of Cruciferous plants, of which several species grow in this country. In Europe, the *T. bursa pastoris* is a very common plant, growing everywhere upon walls, by the roadsides, in gardens, &c., and flowering nearly all the year. Like others of the same natural family, it yields by contact with water a volatile oil, which may be obtained by distillation. The plant is bitter and pungent, and is supposed to possess astringent properties; being employed with asserted advantage in hæmaturia and other hemorrhages. It is also thought to be specially antiscorbutic, and has been used in cases demanding expectorants and diuretics, as in humoral asthma, dropsy, &c. The expressed juice is used in the dose of from two to four fluidounces. A tincture, extract, syrup, &c. have also been prepared, for which formulas may be found in the *Annuaire de Thérapeutique* for 1854 (p. 216). The fresh herb, bruised, is employed as a topical remedy in rheumatism. W.

THUYA OCCIDENTALIS. *Thuja Occidentalis. Arbor Vitæ.* An indigenous evergreen tree, growing wild from Canada to the Carolinas, and cultivated for ornament in gardens. The leaves, or small twigs invested with the leaves, are the parts used. They have an agreeable balsamic odour, especially when rubbed, and a strong, balsamic, camphorous, bitter taste. They were analyzed by A. Kawalier, of Vienna, and found to contain volatile oil, a bitter principle called *pinipicrin*, found also in Pinus sylvestris, sugar, gelatinous matter, a variety of wax, resin, and tannic acid. (See *Chem. Gaz.*, Feb. 1, 1855, p. 45). In a more recent analysis, Kawalier discovered in the leaves a peculiar crystallizable colouring principle, which he names *thujine.* It is of a citron-yellow colour and astringent taste, soluble in alcohol, inflammable, and separable, through the agency of sulphuric acid, into glucose, and another yellow substance, which he calls *thujetin.* A third substance, *thujegenine*, was also obtained, apparently a result of some change in thujine. The formula of thujine is $C_{40}H_{22}O_{24}$. The same chemist determined that the tannic acid of this plant is identical with that which he had previously obtained from the leaves of *Pinus sylvestris*, and to which he had given the name of *pinitannic acid.* (See, for the mode of preparing these principles, and a full account of their properties, the *Chemical Gazette*, Nos. 392 and 393, pp. 61 and 88, A. D. 1859.) In the form of decoction the leaves have been used in intermittent fever, and, according to Schoepf, in coughs, fevers, scurvy, and rheumatism. Dr. J. R. Leaming, of New York, has employed a tincture of the leaves internally, with supposed advantage, in affections believed to be cancerous; and the same remedy has been used locally with prompt effect in venereal excrescences. (*N. Y. Journ. of Med.*, &c., N. S., xiv. 406.) Dr. Benedict has found a saturated tincture useful as an emmenagogue, given in the dose of a teaspoonful three times a day. (*Ibid.*, Nov. 1856, p. 395.) Made into an ointment with lard or other animal fat, the leaves are said to form a useful local application in rheumatic complaints. The distilled water is praised by Boerhaave as a remedy in dropsy. (*Schoepf.*) A yellowish-green volatile oil, which may be obtained from the leaves by distillation, has been used with success in worms. W.

TIN. *Stannum.* This was recognised in the late Ed. and Dub. Pharmacopœias, and in the U. S. of 1850; but is no longer officinal. It has, however, too long ranked among recognised remedies to be passed without notice. Tin is one of the metals which have been known from the earliest ages. It exists generally as an oxide (*tin stone* and *wood tin*), rarely as a sulphuret (*tin pyrites*), and is by no means generally diffused. It is found in England, Spain, Germany, Bohemia, and Hungary, in Europe; in the island of Banca and the Peninsula of Malacca in Asia; in Chili; and at Durango in Mexico. Recently it has been asserted in the daily journals, that tin has been discovered within the territory of the United States, especially in Madison Co., Missouri, where it is even asserted that the largest deposit exists yet known in the world. (*Phila. N. Am. & U. S. Gaz.*, July 25, 1867.) A valuable tin ore has been discovered in the United States, at Jackson, New Hampshire. Tin mines are particularly abundant and rich in the Tenasserim provinces of British India. (*Dr. Royle.*) The Cornwall mines are the most productive, but those of Asia furnish the purest tin. The metal is extracted from the native oxide. When this occurs in its purest state, in detached roundish grains, called *stream tin*, the reduction is effected by heating with charcoal. When the common oxide, called *mine tin*, is melted, it requires to be freed, by pounding and washing, from the adhering gangue; after which it is roasted to drive off sulphur, arsenic, and antimony, and finally reduced in furnaces by means of stone coal. The metal, as thus obtained, is called *block tin*, and is not pure. The purest kind of tin, known in commerce, is called *grain tin.*

Properties. Tin is a malleable, rather soft metal, of a silver-white colour. It may be beaten out into thin leaves, called *tin foil.* It undergoes a superficial tarnish in the air. Its taste is slight, and when rubbed it exhales a peculiar smell. Its ductility and tenacity are small;

when bent to and fro, it emits a crackling noise, which is characteristic. Its sp. gr. is 7·29, melting point 442°, equivalent number 59, and symbol Sn. It forms three oxides, a protoxide, sesquioxide, and deutoxide. The *protoxide* is of a grayish-black colour. When perfectly pure it has, according to Dr. Roth, a red colour. The *sesquioxide* is gray. The *deutoxide* acts as an acid, and exists in two isomeric states, called *stannic* and *metastannic acid.* Stannic acid may be prepared by decomposing bichloride of tin with water. The metastannic acid is formed by acting on tin with nitric acid, which converts it into a white powder. The native crystallized oxide is metastannic acid. These acids, though having the same composition, SnO_2, are perfectly distinct in chemical properties. The stannic acid is soluble, the metastannic insoluble in nitric acid and dilute sulphuric acid. One eq. of potassa requires for saturation one eq. of stannic acid, but five of metastannic acid. Hence the latter is sometimes represented by Sn_5O_{10}.

The tin of commerce is often impure, being contaminated with other metals, introduced by fraud, or present in consequence of the mode of extraction from the ore. A high specific gravity is an indication of impurity. When its colour has a bluish or grayish cast, the presence of copper, lead, iron, or antimony, may be suspected. Arsenic renders it whiter, but at the same time harder; and lead, copper, and iron cause it to become brittle. Pure tin is converted by nitric acid into a white powder (*metastannic acid*), without being dissolved. Boiled with muriatic acid, it forms a solution which gives a white precipitate with ferrocyanide of potassium. A blue precipitate with this test indicates iron, a brown one copper, and a violet-blue one both iron and copper. If lead be present, a precipitate will be produced by sulphate of magnesia. The Malacca and Banca tin, and the English grain tin are the purest kinds found in commerce. Banca tin, from recent analyses by Mulder, appears to be particularly pure, containing only one twenty-fifth of 1 per cent. of foreign metals. Block tin and the metal obtained from Germany are always of inferior quality.

Uses. Tin enters into the composition of bronze, bell-metal, pewter, and plumber's solder. It is used also in making tin-plate, which is sheet-iron coated with tin, in silvering looking-glasses, and in forming the solution of bichloride of tin, a combination essential to the perfection of the scarlet dye. It is employed in fabricating various vessels and instruments, useful in domestic economy and the arts. Being unaffected by weak acids, it forms a good material for vessels intended for boiling operations in pharmacy. We are told that a *false tin foil* is considerably used at present, made by coating lead with tin, and then rolling it out into thin sheets. As tin foil is employed for enclosing medicinal powders, and in other ways is brought into contact with medicinal substances, care should be taken not to use this substituted preparation, lest the patient might be exposed to the poisonous action of lead.

Stanni Pulvis. *U. S.* 1850. *Powder of Tin.* The following directions were given for preparing powder of tin in the U. S. Pharmacopœia of 1850. "Take of Tin *a convenient quantity.* Melt it in an iron vessel over the fire, and, while it is cooling, stir it until it is reduced to a powder, which is to be passed through a sieve." *U. S.* Tin, being very fusible, is easily granulated by fusion, and subsequent agitation while solidifying. On a small scale, the granulation is most conveniently performed in a wooden box, the inside of which has been well rubbed with chalk. This should be afterwards washed away with water; and, as the granulated powder is of unequal fineness, the coarser particles must be separated by a sieve.

Medical Properties and Uses. Powder of tin is used exclusively as an anthelmintic, and is supposed to act by its mechanical properties. It is considered particularly adapted to the expulsion of *Ascaris lumbricoides*, and is also employed to expel the tapeworm. For internal exhibition it should be free from oxidation. The dose is half an ounce, mixed with molasses, given for several successive mornings, and then followed by a brisk cathartic. Dr. Alston was in the habit of administering larger doses for the expulsion of the tapeworm. He began by giving an ounce on an empty stomach, which was followed, for two successive days, by half an ounce each day, and finally by a brisk purge. B.

TONKA BEAN. The seed of *Dipterix odorata* of Willd., the *Coumarouna odorata* of Aublet, a large tree growing in Guiana. The fruit is an oblong-ovate pod, enclosing a single seed, from an inch to an inch and a half long, from two to four lines broad, usually somewhat compressed, with a dark-brown, wrinkled, shining, thin, and brittle skin, and a light-brown oily kernel. The bean has a strong, agreeable, aromatic odour, and a bitterish, aromatic taste. Its active constituent is a crystallizable, odorous substance, analogous to the volatile oils and camphor, and called *coumarin* by Guibourt. It is capable of sublimation; but, to obtain it in crystals in this way, a low temperature is necessary. (Waddington, *Pharm. Journ.*, March, 1868, p. 410.) This substance is sometimes found in a crystalline state, between the two lobes of the kernel. It has been shown by M. Bleib treu to be identical with the odorous principle of *Asperula odorata*, *Trifolium melilotus* and *Anthoxanthum odoratum.* (See *Chem. Gaz.*, Feb. 16, 1852, p. 61.) Mr. W. H. Lippitt, of Wilmington, N. C., having noticed a crystalline exudation upon the leaves of *Liatris odoratissima*, in that neighbourhood, sent a specimen to Prof. Procter, of Philadelphia, who ascertained that it was *coumarin.* According to Mr. Lippitt, this product of the Liatris was collected for the purpose of protecting woollens against moths.

(*Am. Journ. of Pharm.*, Nov. 1859, p. 556.) Dr. Gössmann obtains coumarin in the following manner. The beans, cut finely, are heated for a long time with an equal bulk of alcohol of 0·863, nearly to boiling; and, the tincture being decanted, the residue is treated in the same manner. The tinctures are mixed, the alcohol distilled off until turbidness appears, when four times the bulk of water is added, which precipitates coumarin and fatty matter. The precipitate is then heated to boiling, and the liquid passed through a moistened filter. The fatty matter remains on the filter, and the hot solution which passes deposits the coumarin on cooling. More may be obtained by concentrating the liquid, and may be purified by animal charcoal. One pound of the beans yielded 108 grains of coumarin. (*Ibid.*, June, 1856, p. 211.) The tonka bean is used to flavour snuff, being either mixed with it in the state of powder, or put entire into the snuff-box. Dr. John Cooper, of Philadelphia, has used it with advantage in hooping-cough, in which it relieves the paroxysms, and enables the patient to sleep. He gave from five to eight grains of a fluid extract to children five years old. (*Am. Journ. of Pharm.*, Jan. 1869, p. 27; from *Med. and Surg. Reporter.*) W.

TRIGONELLA FŒNUMGRÆCUM. *Fenugreek.* An annual plant, growing spontaneously in different parts of the South of Europe, and cultivated in France and Germany for the sake of its seeds. These are oblong-cylindrical, somewhat compressed, obliquely truncated at each extremity, one or two lines in length, brownish-yellow externally, yellow internally, and marked with an oblique furrow running half their length. They have a strong peculiar odour, and an oily, bitterish, farinaceous taste, and contain fixed and volatile oil, mucilage, bitter extractive, and a yellow colouring substance. An ounce of the seeds, boiled in a pint of water, renders it thick and slimy. They yield the whole of their odour and taste to alcohol. Their virtues depend chiefly upon their oil and mucilage. On the continent of Europe they are employed in the preparation of emollient cataplasms and enemata, and enter into some officinal ointments and plasters. They are never used internally. W.

TRILLIUM. This is an indigenous genus of pretty, little, herbaceous plants, growing generally in woods and shady places. The roots are reputed to possess valuable remedial properties. They were employed by the aborigines, have been long used in domestic practice in some parts of the country, and were noticed as medicinal in Henry's Herbal, published in 1812. Dr. S. W. Williams published a paper upon them in the *New England Journ. of Med. and Surg.*, in the year 1820, and afterwards another in the *N. Y. Journ. of Med.* (viii. 94). The roots have a somewhat balsamic odour and taste, and produce, when chewed, a sense of heat and irritation, with an increased flow of saliva. A root received by Mr. E. S. Wayne, of Cincinnati, is described by him as an "oblong rhizome, with numerous rootlets attached to it, and of a yellowish-brown colour." Upon the removal of the epidermis, it is white and starchy, and gives a deep blue with tincture of iodine. Mr. Wayne found in the root an acrid principle, analogous to senegin and saponin in the property of frothing with water; half a grain in two ounces of water being sufficient to show this property. He obtained it by treating the powdered root with alcohol by percolation, distilling off the alcohol and adding water as the alcohol escaped, separating an oleo-resin which floated on the surface of the remaining watery liquid, treating the latter with acetate and subacetate of lead so long as a precipitate was produced, filtering, separating the excess of lead by sulphuric acid, again filtering, and setting the clear liquid aside. In the following day a gelatinous precipitate had formed, which, being collected on a filter, washed, and dried, was redissolved in dilute alcohol, and recovered by spontaneous evaporation of the menstruum. A white, amorphous powder was thus obtained, of an acrid taste, soluble in alcohol, and, as above stated, giving in a high degree the frothing property to water. (*Proceed. of Am. Pharm. Assoc.* for 1856, p. 36, also *Am. Journ. of Pharm.*, xxviii. 512.) Besides this acrid principle, the Trillia roots are said to contain volatile oil, gum, starch, extractive, resin, and tannic acid. They are astringent; and tonic, expectorant, and alterative properties have been ascribed to them. They have been used by the vulgar to hasten parturition. The complaints in which they are said to have proved most advantageous are the hemorrhages; but they have been used also in cutaneous affections, and externally in obstinate ulcers. Dr. Williams gave a drachm of the powdered root three times a day. Of the different species *T. erectum* is generally esteemed most active. *T. pendulum* is referred to, in the *Peninsular and Independent Med. Journ.* (Jan. 1859, p. 187), as among the most valued indigenous plants of Michigan; being used especially in menorrhagia. W.

TRIPOLI. *Terra Tripolitana.* An earthy mineral, of a whitish, yellowish, or pale-straw colour, sometimes inclining to red or brown, usually friable, often adhesive to the tongue, and presenting the aspect of argillaceous earth, though differing from clay by the roughness and hardness of its particles, and by not forming a paste with water. The *Venice tripoli* is said to come from Corfu. Tripoli is sometimes artificially prepared by calcining certain argillites. It is used for cleaning and polishing metals. W.

TRITICUM REPENS. *Couch-grass. Dog-grass. Quickens. Chiendent*, Fr. A perennial European plant, very common in gardens and cultivated grounds, where it is considered a troublesome weed. The root, which is the part medically used, is horizontal, creeping, jointed, about as thick as a straw or thicker, inodorous, and of an agreeable, sweetish,

slightly pungent taste. It is used in some parts of Europe, in the form of decoction, as a slightly aperient and nutritive drink; and has been recommended of late in irritable bladder. Great quantities of it are said to be consumed in the hospitals of Paris. The infusion or decoction, in consequence of the sugar which it contains, is susceptible of the vinous fermentation, and alcohol has been obtained from it by distillation. W.

TURPETHUM. *Turpeth. Resin of Turpeth. Résine de Turbith*, Fr. This product, at one time considerably used, but of late better known from having given its name to the *turpeth mineral* or *yellow sulphate of mercury*, than for any valuable property of its own, is really possessed of merits which would seem to render it worthy of a better reputation. It is obtained from the *Ipomœa Turpethum* (*Convolvulus Turpethum*, Linn.), an Indian plant, said to have first been made known in Europe by Dacosta, who brought it to France from Hindostan, and caused a figure of it to be drawn. The root is the only part used. By Mérat and De Lens it is described as "long, of the size of the little finger or larger, covered by a rather thick bark, grayish without, white within, porous, liable to decay, very resinous when fresh, and in this state yielding a juice, capable of coagulating, and constituting, when coagulated, a gum-resin similar to scammony." In choosing the roots, those should be selected in which the bark is perfect, as most of the activity of the root resides in this part. It is without odour, and has little taste. Examined by M. Boutron-Charlard, it was found to contain resin, a fatty substance, volatile oil, albumen, starch, a yellow colouring matter, lignin, salts, and oxide of iron. (*Journ. de Pharm.*, viii. 121.) The root contains 10 per cent. of resin. (M. Andouard, *Ann. de Thérap.*, 1866, p. 118.)

According to M. Spirgatis, this resin is a glucoside, like that of other Convolvulaceæ, insoluble in ether, but soluble in alcohol, to which it imparts a brown colour not removable by animal charcoal. To obtain it pure, the alcoholic solution is concentrated; the resin precipitated by water, boiled with this vehicle, then dried, reduced to powder, digested with ether, and finally redissolved by absolute alcohol, and thrown down by ether. After being treated several times in this way, it is obtained in the state of a brownish resin, yielding on pulverization a gray powder, which strongly irritates the mucous membrane of the nostrils and mouth, and fusible at 360° F. It is inflammable, burning with a smoky flame, and emitting irritant vapours. With strong bases it acts like jalapin, fixes water, and is transformed into a soluble acid. The resin is called *turpethine* by M. Spirgatis. (*Journ. de Pharm.*, 4e sér., i. 236; from *Zeitschr. Chem. Pharm.*, vii. 442.)

Turpeth root is purgative, somewhat less powerful than jalap, and rather slow in its action, in this respect resembling jalap. From one to three drachms may be given in decoction, and from fifteen grains to a drachm in powder. (*Mérat et De Lens.*) But the resin is probably the more expedient form for administration. It has recently been the subject of special examination by M. Andouard, who states, as the result of clinical experiment, that it purges perfectly well, though perhaps somewhat less active than jalap or scammony. Trials have been made with it by others, with the general conclusion, that it might very properly take a place with other efficient cathartics, as aloes, gamboge, resin of jalap, &c. A strong inducement for its general introduction into practice is offered by the abundance in which it may be obtained, while the sources of jalap are scarcely sufficient to meet the demand, and scammony is so liable to adulteration. Turpeth, on the contrary, has no great commercial value, may be cultivated to any desirable extent, and is rarely adulterated. About seven or eight grains of the resin is the dose for an adult. It may be given in sweetened milk or in emulsion. (*Ann. de Thérap.*, 1866, p. 119.) W.

TUSSILAGO FARFARA. *Coltsfoot.* Coltsfoot is a perennial herb, with a creeping root, which early in the spring sends up several leafless, erect, simple, unifloral scapes or flower-stems, five or six inches high, and bearing appressed scale-like bractes of a brownish-pink colour. The flower, which stands singly at the end of the scape, is large, yellow, compound, with hermaphrodite florets in the disk, and female florets in the ray. The latter are numerous, linear, and twice the length of the former. The leaves do not make their appearance until after the flowers have blown. They are radical, petiolate, large, cordate, angular, toothed at the margin, bright-green upon their upper surface, white and downy beneath. The plant grows spontaneously both in Europe and North America. In this country it is found upon the banks of streams in the Middle and Northern States, and flowers in April. The whole of it is employed, but the leaves most so. They should be gathered after their full expansion, but before they have attained their greatest magnitude. The flowers have an agreeable odour, which they retain after desiccation. The dried root and leaves are inodorous, but have a rough, bitterish, mucilaginous taste. Boiling water extracts their virtues. Coltsfoot exercises little sensible influence upon the human system. It is, however, demulcent, and is sometimes used in chronic coughs, consumption, and other affections of the lungs. The expectorant properties which it was formerly thought to possess are not obvious. The leaves were smoked by the ancients in pulmonary complaints; and in some parts of Germany they are at the present time said to be substituted for tobacco. Cullen states that he found the expressed juice of the fresh leaves, taken to the extent of some ounces every day, beneficial in several cases of scrofulous sores; and a decoction of the dried leaves, as recommended by

Fuller, answered a similar purpose, though it often failed to effect a cure. The usual form of administration is that of decoction. An ounce or two of the plant may be boiled in two pints of water to a pint, of which a teacupful may be given several times a day. W.

TUTTY. *Tutia. Impure Oxide of Zinc.* This oxide is formed during the smelting of lead ores containing zinc. It is deposited in the chimneys of the furnaces, in the form of incrustations, moderately hard and heavy, and studded over with small protuberances of a brownish colour on the outside, and yellowish within. As it occurs in commerce, the pieces occasionally present a bluish cast, from the presence of small particles of metallic zinc. Sometimes a spurious substance is sold for tutty, consisting of a mixture of blue clay and copper filings, made into a paste with water, and dried on an iron rod. It is distinguished from the genuine tutty by its diffusing in water and exhaling an earthy smell, and by its greater friability. Tutty is used as an external application only, being employed as a desiccant in excoriations. To fit it for medicinal use it must be reduced to fine powder, which is dusted over the affected part, or applied in the form of ointment. It has been very properly dismissed from the Edinburgh officinal list; its use being superseded by that of the pure oxide. B.

ULTRAMARINE. This fine blue pigment was formerly obtained from *lapis lazuli*, or *lazulite*, a mineral of Siberia. It is now prepared artificially by mixing equal parts of sulphur, carbonate of soda, and silica, adding enough solution of soda to dissolve the silica, and rapidly igniting the mixture. A bluish-green mass results, which becomes blue by ignition in contact with air. It is thought to be a compound of the silicates of alumina and soda with sulphuret of sodium. (*Pharm. Journ.*, xi. 230.) It is very largely manufactured at Nuremberg, in Germany. (*Am. Journ. of Pharm.*, xxviii. 416.) In reference to this manufacture, see a paper by Dr. Ernst Röhrig in the *Chemical News* (Oct. 11 and 25, 1867, pp. 188 and 212). W.

UMBER. *Terra Umbria.* A mineral of a fine compact texture, light, dry to the touch, shining when rubbed by the nail, and of a fine pale-brown colour, which changes to a peculiar beautiful deep-brown by heat. According to Klaproth, it contains 13 parts of silica, 5 of alumina, 48 of oxide of iron, 20 of manganese, and 14 of water in 100. *Burnt umber*, as well as the mineral in its unaltered state, is used in painting. The umber of commerce is said to be brought chiefly from the island of Cyprus. W.

UPAS ANTIAR AND UPAS TIEUTE. Under these names, two poisons have long been used by the natives of Java and other East India islands for poisoning their arrow-heads; and very exaggerated notions have prevailed among the people of the Western World in relation to the tremendously destructive power over animal life of the upas-tree in Java, from which it was supposed that the poison was derived. The tale was told that birds and animals perished when within the influence of its exhalations, and that man came into its near vicinity at the peril of life. All such accounts have proved to be fabulous; but there is no doubt as to the exceedingly poisonous character of the arrow-poison to which reference has been made. It seems now to be pretty well determined that the active ingredient of the *upas antiar* is a gum-resinous exudation proceeding from incisions in the trunk of the *Antiaris toxicaria*, a large tree belonging to the *Urticaceæ*, growing in Java, Celebes, and the neighbouring islands, and described in *Lindley's Flora Medica* (p. 301). Like certain species of Rhus, this plant exhales an aeriform matter, which very unpleasantly affects many of those who approach it, causing eruptions upon the skin and exterior swelling, while others seem altogether insensible to its influence. The juice is mixed with various substances which probably have little other effect than to give a due consistence to the poison. This, whether taken internally or introduced into the system through a wound, acts with extreme violence, producing vomiting, with great prostration, a feeble irregular pulse, involuntary evacuations, and convulsive movements, which are soon followed by death. Brodie, who made experiments with the poison on animals, could observe no sign of special action on the brain, and believed that death was produced by its action upon the heart, which ceased to beat before respiration ceased, and after death was found full of blood, differing in both these respects from its condition under ordinary narcotic poisoning. In other words, the poison seems to rank with digitalis, tobacco, and aconite, rather than with opium, belladonna, &c. From a chemical examination by Pelletier and Caventou, it appears that the antiar owes its activity to a peculiar principle which they named *antiarin*, crystallizable, soluble in water and alcohol, but scarcely so in ether, and consisting of carbon, hydrogen, and oxygen, with the formula $C_{14}H_{10}O_5$. (See *Am. Journ. of Pharm.*, Sept. 1863, p. 474.)

The *upas tieute* is even more poisonous than the *antiar*. This is said to be obtained from a climbing woody plant, growing exclusively in Java, and belonging to the genus Strychnos, specially designated by Leschenault as *Strychnos Tieute*. It is from the bark of the root, according to this author, that the poison is prepared. A decoction of the bark is concentrated to the consistence of syrup, then mixed with onions, garlic, pepper, &c., and allowed to stand till it becomes clear. Leschenault, having dipped the point of an arrow in the poison and allowed it to dry, pricked a chicken with it, which died in a minute or two in violent convulsions. MM. Delille and Magendie found that the poison had not lost its strength in four years. (Hammond, *Am. Journ. of Med. Sci.*, Oct. 1860, p. 366.) A

gentleman of Berlin took 3 grains of the poison, apparently for the relief of headache. This disappeared, but a feeling of oppression of the stomach came on, with stiffness along the spine, in half an hour, succeeded by a feeling as of a violent shock through the system, spasmodic contraction and rigidity of the muscles, loss of speech, difficulty of deglutition; in short, with all the symptoms of a poisonous dose of nux vomica. He recovered under the use of emetics followed by opiates. (*Chemist and Druggist*, May 15, 1863.) In fact the poison has upon analysis been found to contain strychnia, as might have been suspected from its origin.

Dr. Wm. A. Hammond made some experiments with a poisonous substance brought by Dr. Ruschenberger from Singapore, which proved to have the combined effects of the two poisons above mentioned, both diminishing directly the power of the heart, and causing tetanic spasms of the muscles; suggesting the idea that it might be a mixture of the antiar and tieute; but Dr. Hammond seems, from other considerations, to have been led to the opinion that it had a different origin from either. (*Am. Journ. of Med. Sci.*, Oct. 1860, p. 371.) W.

URATE OF AMMONIA. *Ammoniæ Uras.* ($NH_4O,HO+N_4C_{10}H_2O_4$.) This is an acid salt, and may be formed by digesting uric acid in solution of ammonia. Uric acid is generally obtained from the dried and powdered excrement of the boa serpent, and of other large snakes, by dissolving it in a weak solution of potassa with the aid of heat, and precipitating the uric acid from the filtered solution by muriatic acid, added in excess. Urate of ammonia is a white, amorphous, very sparingly soluble salt. It is a constituent of some varieties of guano; and the medicinal properties of that substance are attributed by some to its presence. This salt has been used with good effects by Dr. Bauer, of Germany, as an external application, in the form of ointment, in chronic cutaneous eruptions, and in tuberculous diseases of the lungs. The ointment is made with a scruple of the salt to an ounce of lard, and is applied to the eruptions night and morning, and, in the pectoral disease, by friction, night and morning, alternately to the back and front of the chest. (*Medico-chirurg. Review*, July, 1852, p. 207; from *Buchner's Repert.*) The urates should be given with caution internally, for fear of producing oxalic acid in the urine. When uric acid was given to rabbits in the dose of from thirty to forty-five grains in their daily food, Dr. Neubauer found that the urea in the urine was considerably increased, showing that the acid was transformed into urea in the economy. When, however, a large quantity of uric acid was given, the urine, in addition to an increased amount of urea, contained some uric acid, and traces of oxalic acid. (*Ranking's Abstract*, July to Dec. 1857, p. 298.) B.

UREA. ($C_2H_4N_2O_2$.) This substance, the characteristic organic constituent of urine, was shown by Wöhler to be identical with the hydrated cyanate of ammonia (NH_3, NC_2O+HO), which furnishes the first example of a complex organic product artificially formed. When obtained from urine, the most convenient process is that proposed by Dr. Gregory, which consists in saturating concentrated urine with oxalic acid, dissolving in water the oxalate of urea formed, decolorizing the solution with animal charcoal, digesting it with carbonate of lime, separating the precipitated oxalate of lime by filtration, and concentrating the filtrate that crystals may form. For the mode of obtaining artificial urea, the reader is referred to chemical treatises. For a new method, which claims to have better results than that previously pursued, the reader is referred to a paper by Mr. John Williams, contained in the *American Journal of Pharmacy* (May, 1868, p. 260); from the *Chemist and Druggist* for March, 1868. Mr. Williams makes cyanate of lead the basis of his operations, which he prepares by heating together cyanide of potassium and red lead, exhausting the product with cold water, precipitating with nitrate of baryta, and treating the mother-liquid with nitrate of lead. From the cyanate of lead thus obtained he prepares urea by digesting together equivalent quantities of that salt and sulphate of ammonia, filtering and evaporating.

Urea is in the form of four-sided prismatic crystals, colourless and free from odour when pure, somewhat resembling nitre in appearance, and having a similar saline, cooling taste. It is soluble in its weight of cold water, and in every proportion in hot water. Though without acid or alkaline reaction, it is capable of uniting with several acids, forming crystallizable compounds, having all the characters of salts. Its action on the inferior animals has recently been investigated by M. Gallois. Given to rabbits in the dose of five drachms, it acted as a poison, producing accelerated respiration, weakness of the limbs, tremblings, convulsions, tetanus, and death. Administered in the daily dose of 75 grains for three days, it passed unaltered into the urine, appearing in the secretion in 30 or 40 minutes. (*Chem. Gaz.*, July 1, 1857.)

Urea was proposed many years ago by the French physicians as a diuretic; and its use in this way has been revived by Dr. T. H. Tanner, of London. In the few cases in which Dr. Tanner tried the remedy, it acted as a powerful diuretic without giving rise to any unpleasant symptom whatever. Prof. Mauthner, of Vienna, also bears testimony to its diuretic properties, having found it, in two cases occurring in children, promptly to remove the anasarca following scarlet fever. The dose for an adult to begin with is ten grains every six hours, dissolved in water, flavoured with syrup; the action of the medicine being aided by the free administration of diluents, and by keeping the skin moderately cool. (See *Braithwaite's Retrospect*, xxv. 161.) B.

URTICA DIOICA. *Common nettle.* A well-known perennial herbaceous plant, growing both in Europe and the United States, by the roadsides, in hedges, and gardens. The leaves, seeds, and roots were formerly officinal. They were deemed diuretic and astringent, and were employed in nephritic complaints, hemorrhages, consumption, jaundice, worms, &c. Dr. Benavente has obtained extraordinary success, in the treatment of uterine hemorrhage, both passive and symptomatic, from a decoction of the nettle, made with thirty parts of the plant to five hundred parts of water (℥i to Oj) given in cupful doses, several times a day. (*Ann. de Thérap.*, 1867, p. 92; from *Siglo Medico.*) The young shoots are boiled and eaten by the common people as a remedy in scurvy; and the fresh plant is sometimes used to excite external irritation in cases of torpor and local palsy, the part being beaten with it till the requisite degree of action is produced. The irritant effect of the nettle, applied to the skin, is said to be owing to the presence of free formic acid in the sharp hairs. (*Am. Journ. of Pharm.*, xxii. 181.) The root of the Urtica dioica was examined by Mr. Benj. Shoemaker, with the view of discovering the principle to which it owes its diuretic properties. This he thinks he has found in a volatile oil. (*Ibid.*, Nov. 1866, p. 492.) *U. urens*, or *dwarf nettle*, which is an annual plant, and smaller than the former species, has similar properties, and is used for the same purposes. This species also grows wild both in America and Europe. The two plants were formerly distinguished by the names of *urtica major* applied to *U. dioica*, and of *urtica minor* to *U. urens.* Dr. U. B Johnson, of Marion, Alabama, has found U. urens very efficacious in uterine hemorrhage. (*N. Orleans Med. and Surg. Journ.*, vi. 452.) W.

VALERIANATE OF BISMUTH. *Bismuthi Valerianas.* This salt is formed by double decomposition between solutions of ternitrate of bismuth and valerianate of soda. Valerianate of bismuth precipitates as a white powder, which is washed with water, and dried with a gentle heat. It has been recommended by Righini in neuralgia, and in painful affections of the stomach. The dose is from half a grain to two grains, repeated several times a day, and given in the form of pill. B.

VALERIANATE OF IRON. FERRI VALERIANAS. *Dub.* This officinal of the late Dublin Pharmacopœia has not been retained in the British. The following was the Dublin process. "Take of Valerianate of Soda *five ounces and* 164 *grains* [avoirdupois]; Sulphate of Iron *four ounces* [avoird.]; Distilled Water *one pint* [Imperial measure]. Let the Sulphate of Iron be converted into a persulphate, as directed in the formula for *Ferri Peroxydum Hydratum*, and, by the addition of distilled water, let the solution of the persulphate be augmented to the bulk of eight [fluid]ounces [Imp. meas.]. Dissolve the Valerianate of Soda in ten [fluid]ounces of the Water, then mix the two solutions cold, and, having placed the precipitate which forms upon a filter, and washed it with the remainder of the Water, let it be dried by placing it for some days rolled up in bibulous paper on a porous brick. This preparation should be kept in a well-stopped bottle." The first step in this process is to convert the sulphate of protoxide of iron into the tersulphate of sesquioxide. Then by a double decomposition between this salt and valerianate of soda, sulphate of soda is formed in solution, and tervalerianate of sesquioxide of iron is precipitated. The proper proportion of the reacting salts is three equivalents of valerianate of soda, and one of tersulphate of sesquioxide of iron; and the resulting salts are three eqs. of sulphate of soda, and one of tervalerianate of sesquioxide of iron.

Properties, &c. This salt is in the form of a dark tile-red, loose, amorphous powder, having a faint odour and taste of valerianic acid. It is insoluble in cold water, and decomposed by boiling water, which extracts all its acid, and leaves the sesquioxide of iron behind. It is soluble in alcohol. Citrate and tartrate of iron, impregnated with oil of valerian, have been fraudulently sold for valerianate of iron. The genuine salt may be distinguished from these substitutions by being insoluble in water and soluble in alcohol, and by the action of a little dilute muriatic acid, which sets free the valerianic acid, readily recognised by its disagreeable odour, which is quite distinct from that of the oil of valerian. In relation to the modes of distinguishing the true from the spurious valerianates, see *Pharm. Journ.* (viii. 577). See also, on the composition, properties, and preparations of this salt, a paper by Mr. Francis Sutton, of Norwich, England, in the same journal (2d ser., viii. 131). Valerianate of iron has been given in hysterical affections, complicated with chlorosis. The dose is about a grain, repeated several times a day. B.

VENETIAN RED. *Bolus Veneta.* A dull-red ochrey substance used in painting.

VERBASCUM THAPSUS. *Mullein.* This is a biennial plant, with an erect, round, rigid, hairy stem, which rises from three to six feet in height, and is irregularly beset with large sessile, oblong or oval, somewhat pointed leaves, indented at the margin, woolly on both sides, and decurrent at the base. The flowers are yellow, and disposed in a long, close, cylindrical, terminal spike. The mullein is common throughout the United States, growing along the roadsides and in neglected fields, and springing up abundantly in newly cleared places, at the most remote distance from cultivation. It is, however, generally considered as a naturalized plant, introduced originally from Europe, where it is also abundant. It flowers from June to August. The leaves and flowers have been employed. Both have a slight, somewhat narcotic smell, which in the dried flowers becomes agreeable. Their taste is mucilaginous, herbaceous, and bitterish, but very feeble. They impart their virtues

to water by infusion. Mullein leaves are demulcent and emollient, and are thought to possess anodyne properties, which render them useful in pectoral complaints. On the continent of Europe, an infusion of the flowers, strained in order to separate the rough hairs, is considerably used in mild catarrhs. Dr. Home found a decoction of the leaves useful in diarrhœa. The infusion or decoction may be prepared in the proportion of an ounce of the leaves to a pint of water, and given in the quantity of four fluidounces. Dr. N. R. Newkirk, of Bridgeton, N. J., informed the author that he had found the smoking of dried mullein leaves useful in aphonia from irritation of the larynx. The leaves are also employed externally, steeped in hot water, as a feebly anodyne emollient. An ointment is prepared from them in the recent state, and used for the same purposes. It may be made in the same manner as ointment of stramonium, by boiling the leaves in lard. It will be found advantageous to moisten them with water previously to the boiling. W.

VERBENA OFFICINALIS. *Vervain.* This is a common European weed, growing on the roadsides, in the vicinity of towns and villages. Its sensible properties do not indicate the possession of medical virtues; as it is nearly inodorous, and has only a slightly astringent, bitterish taste. By the ancients it was highly esteemed both as a medicine, and as a sacred plant employed in certain religious rites. In modern times, superstitious notions in relation to its virtues are still entertained; and the suspension of the root around the neck by a white riband, has been gravely recommended for the cure of scrofula. The leaves, bruised and made into a cataplasm, are used by the vulgar as a remedy in severe headache, and other local pains. The plant, however, is probably inert. An American species, *V. hastata*, is more bitter than the European, and is said to be emetic. It is not, however, used in regular practice. Schoepf states that the root of *V. urticifolia*, another indigenous species, has been advantageously used in poisoning from the Rhus Toxicodendron. It is prepared by boiling it in milk and water along with the inner bark of the white oak. W.

VERDITER. Two preparations of copper, employed as pigments, are known by this name in commerce, and are distinguished by the epithets of blue and green. *Blue verditer* is prepared in London from the solution of nitrate of copper obtained in precipitating silver by copper. According to Gray, this solution is poured hot upon whiting (carbonate of lime), and the mixture stirred every day till the liquor loses its colour, when it is decanted, and fresh portions added till the proper colour is obtained. By a process for procuring this pigment, invented by Pelletier, the solution of nitrate of copper is decomposed by quicklime, and the precipitate, after being washed, is incorporated intimately with another portion of quicklime. By the former process, a carbonate of copper is obtained; by the latter, a mixture of the hydrated oxide of copper and hydrate of lime. *Green verditer* is prepared by precipitating a solution of nitrate of copper by chalk or a white marl, and consists of carbonate of copper mixed with an excess of the calcareous carbonate. W.

VERONICA OFFICINALIS. *Speedwell.* Several species of Veronica, common to Europe and this country, have been medicinally employed. Of these V. officinalis, and *V. Beccabunga* or *brooklime*, are the most conspicuous. *V. officinalis* has a bitterish, warm, and somewhat astringent taste. Examined by Enz, it was found to contain, in the fresh juice and an extract from the herb, a bitter principle soluble in water and alcohol, but scarcely so in ether, and precipitated by the salts of lead but not by tannic acid; an acrid principle; red colouring matter; a variety of tannic acid producing a green colour with the salts of iron; a crystallizable fatty acid, with malic, tartaric, citric, acetic, and lactic acids; a soft, dark-green bitter resin; and mannite. Prof. Mayer, of N. York, in an examination of the herb, found evidences of the existence of an alkaloid, and a small quantity of a saponaceous principle. (*Am. Journ. of Pharm.*, July, 1863, p. 209.) The plant has been considered diaphoretic, diuretic, expectorant, tonic, &c.; and was formerly employed in pectoral and nephritic complaints, hemorrhages, and diseases of the skin, and in the treatment of wounds. The *beccabunga*, which is very succulent, was used in the fresh state with the view of purifying the blood, and as a remedy in scurvy. Both plants, however, are at present out of use. W.

VIBERNUM PRUNIFOLIUM. *Black Haw.* (See *Gray's Manual*, p. 167.) This is a tree-like shrub, growing southward from New York and Ohio, and remarkable for the beauty of its foliage and flowers. Attention was first called to the medical virtues of this plant by Dr. D. L. Phares, of Newtonia, Miss., who considers it as "nervine, antispasmodic, astringent, diuretic, and tonic," and recommends it in the nervous disorders of pregnancy, and as peculiarly efficacious in preventing miscarriage, whether habitual, or threatened as the result of accident, or criminal design. In this latter application of the remedy, his report is confirmed by the experience of a writer in the *Atlanta Medical and Surgical Journal*, who used it with complete success in two cases. The bark is given in infusion or decoction, of which, when the symptoms are urgent, an ounce or two may be given every two or three hours. (*Boston Med. and Surg. Journ.*, Oct. 10, 1867, p. 212.) W.

VISCUM ALBUM. *Mistletoe.* A European evergreen parasitic shrub, growing on various trees, particularly the apple and other fruit trees, and forming a pendent bush from two to five feet in diameter. The plant is famous in the history of druidical superstition. In the religious rites of the Druids the mistletoe of the oak was employed, and

hence was afterwards preferred when the plant came to be used as a remedy; but it is in fact identical in all respects with those which grow upon other trees. The fresh bark and leaves have a peculiar disagreeable odour, and a nauseous, sweetish, slightly acrid and bitterish taste. The berries, which are white, and of about the size of a pea, abound in a peculiar viscid principle, and are sometimes used in the preparation of bird-lime, of which this principle is the basis. Mistletoe is said to be capable of vomiting and purging when largely taken. A case has been recorded by M. Gampert, in France, in which a child three years old was poisoned by eating the berries. Vomiting and prostration were produced, and on the arrival of the physician the patient was found insensible, with a fixed and somewhat contracted pupil, coldness of the skin, and convulsive movements of the extremities. An emetic brought away a considerable quantity of the berries, and the child recovered. (*Ann. de Thérap.*, 1859, p. 36.) A fatal case is recorded in the *Medical Times and Gazette* (Jan. 1867, p. 26), in which a child a year old died comatose from the effects of these berries, which had been given by a young sister, though the stomach was evacuated, and a large number of the berries discharged. The plant was formerly looked upon as powerfully antispasmodic, and was highly esteemed as a remedy in epilepsy, palsy, and other nervous diseases; but it is now out of use. The leaves and wood were given in the dose of a drachm in substance, and of an ounce in decoction. One or more species of Viscum grow in the United States, but are little used. Dr. Henry Dye, of Texas, records several cases of children poisoned by eating the berries of a species growing on the elm, probably *Viscum flavescens* of Pursh, *Phoradendron flavescens* of Nuttall. (See *Gray's Manual*, p. 382.) The prominent symptoms were vomiting and great thirst, followed by frequent discharges of bloody mucus from the bowels, with tenesmus. One of the children was found in a collapsed state, in which death took place. Dr. Dye states also that, in other instances, as he had been informed, children had eaten the berries without any ill effect. (*Memphis Med. Recorder*, iv. 344.) W.

WHITING. This is essentially the same as prepared chalk, being made by the pulverization and elutriation of crude chalk. It is used as a coarse paint, and for various purposes in the arts, for which carbonate of lime is requisite. *Paris white* is a variety of the same material. W.

WINE, AROMATIC. *Aromatic Wine.* The following formula for an aromatic wine, handed to us by Prof. Procter, merits notice, if only for its extensive use. "Take of Sage, Thyme, Hyssop, Spearmint, Wormwood, Origanum, each, in coarse powder, *half a troyounce;* Alcohol *a fluidounce;* Claret Wine *two pints.* Mix the Alcohol and Wine, and, having moistened the powders with a portion of the mixture, pack the mass in a percolator, and pour upon it the remainder of the menstruum. When the liquid has disappeared, add Alcohol diluted with three times its bulk of water, until a pint of filtered liquid has passed." The alcohol is added to the claret wine to give it greater stability. Though not officinal, we are informed that this wine, the formula for which was introduced from France, is much employed in this neighbourhood, and to some extent elsewhere in the U. States. It no doubt possesses strong tonic and aromatic properties, and may be used in cases of enfeebled digestion, especially when accompanied with gastric pains and flatulence; but its chief employment is externally by way of fomentation, and as a stimulant to feeble and unhealthy ulcers. It possesses the advantage over the aromatic and tonic tinctures that it is less stimulating. The dose may be from one to four fluidrachms. W.

WINTER'S BARK. WINTERA. *U. S.* 1850. *The Bark of Drimys Winteri.* The following is introduced from *Part* I., because the medicine is no longer recognised in the U. S. Pharmacopœia. The genus *Drimys* belongs to Polyandria Tetragynia in the Linnæan system, and to the natural order Magnoliaceæ (*Juss.*), Winteraceæ (*Lindley*). The following is the generic character. "*Calyx* with two or three deep divisions. *Corolla* with two or three petals, sometimes more numerous. *Stamens* with the filaments thickened at the summit, and anthers having two separate cells. *Ovaries* from four to eight, changing into the same number of small, many-seeded berries." (*A. Richard.*) This plant, which is figured in *Carson's Illustrations of Medical Botany* (i. 11, pl. 5), is an evergreen tree, varying very much in size, sometimes rising forty or fifty feet in height, sometimes not more than six or eight feet. The bark of the trunk is gray, that of the branches green and smooth. Its leaves are alternate, petiolate, oblong, obtuse, somewhat coriaceous, entirely smooth, green on their upper surface, of a pale-bluish colour beneath, with two caducous stipules at their base. The flowers are small, sometimes solitary, but more frequently in clusters of three or four, upon the summit of a common peduncle about an inch in length, simple, or divided into as many pedicels as there are flowers. The tree is a native of the southern parts of South America, growing along the Straits of Magellan, and extending as far north as Chili. According to Martius, it is found also in Brazil. The bark of the tree was brought to England, in the latter part of the sixteenth century, by Captain Winter, who attended Drake in his voyage round the world, and while in the Straits had learned its aromatic and medicinal properties. Since that period, a bark has been occasionally employed in medicine under the name of Winter's bark; but it is now believed not to have been derived from Drimys Winteri; as it does not correspond with the specimens of the bark obtained from that tree, still preserved in the cabi-

nets of Europe. The origin of the commercial Winter's bark is unknown. The following is the description of a specimen which came into our possession many years since. It corresponds closely with Guibourt's description of commercial Winter's bark. It is in quilled pieces, usually a foot in length, and an inch or more in diameter, appearing as if scraped or rubbed on the outside, where the colour is pale-yellowish or reddish-gray, with red elliptical spots. On the inside the colour is that of cinnamon, though sometimes blackish. The pieces are sometimes flat and very large. The bark is two or three lines in thickness, hard and compact, and when broken exhibits on the exterior part of the fracture a grayish colour, which insensibly passes into reddish or yellowish towards the interior. The powder resembles in colour that of Peruvian bark. The odour is aromatic, the taste spicy, pungent, and even burning. Winter's bark was found by M. Henry to contain resin, volatile oil, colouring matter, tannic acid, several salts of potassa, malate of lime, and oxidized iron. The presence of tannic acid and oxide of iron serves to distinguish it from *canella alba*, with which it has often been confounded. The bark above described as commercial Winter's bark is destitute both of tannic acid and oxide of iron, and cannot, therefore, be the bark examined by M. Henry.*

Medical Properties and Uses. Winter's bark is a stimulant aromatic tonic, and was employed by Winter as a remedy for scurvy. It may be used for similar purposes with cinnamon or canella alba, but is scarcely known in the medical practice of this country. The dose of the powder is about half a drachm. Another species, the *Drimys Chilensis* of De Candolle, growing in Chili, yields a bark having similar properties. (Carson, *Am. Journ. of Pharm.*, xix. 81.) W.

WOORARI. *Woorara. Woorali. Urari. Curare.* This is a powerful poison, prepared by the aborigines in the interior of British Guiana, and used for arming the points of their weapons. It has the aspect of a black extract, brittle, and of a resinoid appearance. But the specimens, as brought into Europe and this country, vary much in character, at least in their energy of action on the cerebral system. M. C. Bernard has experimented with ten or twelve specimens brought to him from S. America, some of which appeared nearly identical, while others differed in the relation of one to six. (*Journ. de Pharm.*, 4e sér., ii. 166.) Various opinions have been advanced in relation to its source and preparation; but the most probable account is that of Dr. Hancock, who states, from information derived from the natives, that it is a watery extract from the bark of a gourd-like plant. It has been stated that the plant producing it is a Strychnos, and Sir R. H. Schomburgk, who claims to have seen the plant, proposes to name it *Strychnos toxifera.* But the facts that the poison acts in a mode directly opposite to that of strychnia in destroying life, and that chemists have been unable to detect that alkaloid in it, are, we think, sufficient proof that Schomburgk must have been mistaken on this point. (See *Pharm. Journ.*, xvi. 502.) The probability is that it is derived from different plants, and Schomburgk gives the native names of eight which he says enter into its constitution. (*B and F. Medico-chir. Rev.*, Oct. 1865, p. 526.) Nor is it always identical, for very different effects have been obtained on the system from different substances, brought from S. America. It has been conjectured that the poison from the fangs of serpents is mingled with, if it does not constitute the active ingredient of the woorari. But this is contradicted by those who have had the best opportunities of ascertaining its mode of preparation; and is also opposed by the fact, that, unlike the venom of snakes, this poison does not occasion local inflammation when inserted into a wound, but appears to act exclusively on the nervous system, through the medium of the blood. In order that it may act, it must find entrance into the circulation; and hence, when swallowed, it does not in general prove poisonous, either because it cannot penetrate the mucous membrane, or because it is altered in the stomach. It would not, however, be altogether safe to rely on its innoxiousness when swallowed; for, in an empty condition of the stomach, and taken in large doses, it has been found by Dr. John W. Green and others to cause death in some animals. (*Am. Med. Gaz.*, vi. 299.) It appears also, from the experiments of MM. Pelouze and Bernard, to be absorbed as quickly from the air-passages as when inserted into the cellular tissue, and, when thrown into the rectum, produces its peculiar effects, though very slowly. (*Journ. de Pharm.*, Août, 1856, p. 150.) M. C. Bernard thinks that its apparent want of effect, when applied to the mucous membranes, is owing to the fact that it passes through that tissue into the circulation so slowly that it is eliminated by the different secretions as fast as it enters. (*B. and F. Med.-chir. Rev.*, Oct. 1865, p. 527.)

* M. Guibourt, in the third edition of his "Drogues Simples," published in 1850, gives the following description of a specimen of the true Winter's bark, presented to him by Robert Brown, and labelled "*Port Famine, Captain P. King, Drimys Winteri.*" The bark is 3 millimetres (1·18 of an inch) thick, and covered with a grayish-white, very thin, and rather smooth epidermis. It is of a deep reddish-brown colour internally, and has a spongy appearance, especially in the part in contact with the wood, where it appears to be formed of longitudinal, radiating ligneous layers, isolated one from the other. It has a strong odour, somewhat analogous to that of canella and slightly camphorous, and a taste in like manner very aromatic, with considerable acrimony. Another specimen brought from the Straits of Magellan, in 1840, bears a close resemblance to the above, being in quills as large as the little finger, with a thickness of 2 millimetres, and an epidermis thin, smooth, and of a whiteness strongly contrasting with the reddish-brown colour of the interior. Beneath the epidermis there is a certain number of very compact concentric layers; but most of the thickness of the bark is formed of radiating and distinct ligneous layers, altogether like those of the preceding specimen. Guibourt also describes the barks of two other species of Drimys, those of *D. Mexicana* and *D. Granatensis*, growing respectively in Mexico and New Gra ada, both of which have considerable resemblance to the preceding.—(Tom. iii. pp. 681,682.)

When this article was originally written, the following is a summary of what was known of the effects of this poison. When it is inserted in a wound, the animal speedily falls into stupor, and dies in a few minutes, the heart continuing to act for some time after respiration has ceased. If artificial respiration is resorted to before the heart has ceased to act, and is sustained, the animal recovers. From numerous experiments, performed by different persons, there is reason to believe that woorari acts by paralyzing the nervous centres of respiration and motion, without producing essentially any discoverable alteration in the blood or solid tissues. Its action is therefore directly opposite to that of strychnia; and it is said to serve as an antidote to that poison by producing relaxation of the contracted muscles. Its peculiar mode of action has even suggested its remedial use in tetanus. A horse suffering under tetanus was inoculated by Mr. Sewell with woorari. In ten minutes apparent death was produced, when the animal was revived by artificial respiration; and the symptoms of tetanus did not return, though death occurred next day, as was supposed, from overeating. (*Pharm. Journ.*, xvi. 506.) In several cases of tetanus in which it was tried by M. L. Vella, in an hospital at Turin, it appeared to afford relief in all, and in one instance recovery took place. (*Arch. Gén.*, Oct. 1850, p. 1.) But as we have other medicines at least equally effectual, and of which the precise strength is better known, it would not be advisable to trust a case to this remedy. It is said that chlorine and bromine neutralize entirely the effects of the poison (*Ibid.*, p. 504); and, from the experiments of Drs. Brainard and Green, there can be little doubt that iodine has the same effect. It was ascertained by them that woorari, mixed with solution of iodine and iodide of potassium, had no effect when introduced into a wound; and that, if introduced alone, its effects were quite neutralized by subsequent injection of the solution; a cupping-glass being applied so as to prevent the absorption of the poison before the iodine could be brought into contact with it. (*Am. Med. Gaz.*, vii. 305.)

The attempts first made to isolate the poisonous principle of woorari were without satisfactory results. Dr. Heintz succeeded in obtaining the poison in an exceedingly concentrated form, but not entirely separated from other principles. (*Ibid.*, vii. 6.) In 1828, MM. Boussingault and Roulin separated a substance which they regarded as an alkaloid, but which neither they nor other chemists obtained in a crystalline state. At length, however, M. W. Preyer, at the urgent request of M. Bernard, who desired to find some physical test of the identity of the different substances which bore the common name of curare, undertook a laborious investigation into the subject, and succeeded in isolating a crystallizable alkaloid, which is undoubtedly the active principle of woorari, and which has received the appropriate name of *curarine* (*curaria*). From the different specimens examined by him he extracted the same alkaloid; and it is no doubt common to all the varieties of this poison which produce its characteristic effects on the system. The following is the process employed by him. It was first necessary to separate substances added by the Indians to give consistence to the poison, and aid in its preservation. Such are the resin, gum, and perhaps the lime of the woorari. For this purpose he treats the poison successively with alcohol and water, both of which dissolve the alkaloid, though the former less than the latter. Having added a few drops of a saturated solution of carbonate of soda to the powdered woorari, he treats this with absolute alcohol boiling hot, then distils off the alcohol, and adds distilled water to the residue in the retort. Having filtered the watery solution, he adds solution of bichloride of mercury in excess, which precipitates the whole of the curaria. The precipitate is suspended in water, and treated with a current of sulphuretted hydrogen, which throws down sulphuret of mercury, leaving muriate of curaria in solution. To obtain this pure, however, it is necessary to repeat the treatment with the bichloride several times. A colourless, or nearly colourless solution is thus obtained, from which the muriate of curaria crystallizes under the receiver of an air-pump. Another proceeding is given by M. Preyer, in which phosphomolybdic acid is employed as the precipitant. The alkaloid may be obtained from the muriate in the ordinary mode. Besides the muriate, he has obtained the nitrate, sulphate, and acetate, all soluble and crystallizable. Curaria differs from all the other crystallizable alkaloids, with one exception, in containing no oxygen. It consists of carbon, hydrogen, and nitrogen, and M. Preyer presents as a provisional formula $C_{10}H_{15}N$. Curaria is extremely deliquescent, of an extreme and persistent bitterness, crystallizing in quadrilateral prisms, which are colourless, soluble in water and alcohol in all proportions, little soluble in chloroform or amylic alcohol, insoluble in anhydrous ether, benzole, oil of turpentine, or sulphuret of carbon. It very feebly changes litmus blue, and its soluble salts do not redden it. Pure concentrated sulphuric acid gives it a very durable magnificent blue colour, which is not the case with strychnia. With bichromate of potassa the same acid develops the same violet colour as with strychnia, but much more persistent. Concentrated nitric acid renders it purple. By these tests curare may be readily detected in the fluids of animals poisoned with it. (*Journ. de Pharm.*, 4e sér., ii. 296.)

In reference to the effects of curaria on the system, M. Bernard has proved that it is identical in the character of its operation with woorari, but vastly more powerful, according to M. Bernard at least twenty times more powerful than the substance from which it was extracted. There can be no doubt, therefore, that it is the active principle of woorari

and that anything which may be offered under this name, has no claims to it unless it is capable of furnishing more or less curaria. The identity of effect is so complete, that the same difficulty of absorption by the intestinal canal which characterizes woorari, belongs also to the alkaloid. (*Journ. de Pharm.*, 4e sér., ii. 167.)

After the publication of the eleventh edition of the Dispensatory, elaborate and highly interesting experiments were made by Drs. Wm. A. Hammond and S. Weir Mitchell on the woorari poison, of which we give a brief abstract, referring for a full account of them to a communication by those gentlemen to the *American Journal of the Medical Sciences* (July, 1859, p. 13). The specimens operated on were of two kinds, named respectively *corroval* and *vao*, and were brought by Drs. Ruschenberger and Caldwell of the U. S. Navy, from New Granada, S. America. 1. *Woorari*, variety *Corroval*. This was in dark-brown lumps, having the appearance of a vegetable extract, and of an intensely bitter and persistent taste. Under the microscope it presented the appearance of vegetable remains, but nothing animal. It yielded its active properties to water and alcohol, and was found to contain a peculiar alkaloid, which they propose to call *corrovalia*, and which they ascertained to produce on the system the same effects as corroval itself. These were to some extent similar to those obtained from woorari by preceding experimenters, yet with so much difference as to lead to the conclusion, that the poison was derived from a different source. In a few minutes after the introduction of the poison through a wound, paralytic phenomena became obvious, and the animal soon died, without preliminary spasm or convulsions. But the heart, instead of continuing to act after apparent death, had entirely ceased to beat, and had quite lost its irritability, so that it could not be excited by galvanism. They inferred that the action of the poison is directly and primarily on the heart, possibly through the ganglia contained in its tissue. The capillary circulation was always arrested a minute or two before the heart's actions, which the authors ascribe to paralysis of the sympathetic. There was no evidence whatever, whether chemical or physiological, of the presence of strychnia in the poison. 2. *Woorari*, variety *Vao* or *Bao*. This, like the preceding, had the characters of a vegetable extract, with a large proportion of vegetable but none of animal remains. It contained the same alkaloid as the corroval, but in smaller proportion; and its effects on the system though much feebler than those of the other variety, were of the same general character They inferred from their observations that it was the same poison, but in a diluted state

Experiments have recently been made in France by MM. Voisin and Liouville, followed by others by M. Du Cazal, which may be considered as determining the physiological action, and to a considerable extent the therapeutical applicability of woorari We have not space for these in detail, and must content ourselves with giving the general results obtained. The poison was introduced into the system hypodermically. A filtered aqueous solution was employed by M. Du Cazal; as it was found to exercise the whole effect of the poison on the system, with only temporary local irritation if any, while the poison injected unaltered, or in unfiltered solution, in consequence of the insolubility of some of its ingredients, caused persistent inflammation, often ending in suppuration, and lasting for months. It was found, as on former occasions, that the poison introduced into the stomach produced comparatively little effect. It was also found, as stated by Bernard, that its action could be to a considerable extent controlled by applying a ligature around the limb above the point of insertion, so as to arrest the return of blood. The experiments were first performed on the lower animals, and afterwards, when a safe dose had been determined, were cautiously extended to the human subject. The effects on the lower animals were always characteristic; and in no instance were symptoms produced such as are caused by other poisons, as strychnia, &c. The nerves of voluntary motion were always disordered, often completely paralyzed, but they retained their irritability, as shown by their contraction under electric excitement, and cutaneous sensibility was unimpaired. In fatal cases a remarkable increase of the temperature of the rectum was observed, amounting to from 5° to 7° F., while little if any change was noticed on the surface. The circulation, at first excited, gradually became depressed, ending in asphyxia. Moderate doses usually dilated the pupils; while, after large doses, though at first widely dilated, they rather suddenly contracted; and subsequently there was an alternation between the two conditions. Double exophthalmia was also observed after fatal doses. As regards the effects on the human subject, MM. Voisin and Liouville divide the effects into two classes, according to their severity. The milder symptoms are chiefly exhibited in the circulatory system. The pulse is increased in force and frequency, the respiration is rendered somewhat more frequent, the temperature is slightly elevated, perspirations sometimes occur, and the urine is augmented in quantity, is remarkably light coloured, and contains glucose. From larger quantities of the poison violent febrile phenomena occur, commencing with the characteristic symptoms of a severe chill. There are shivering, chattering of the teeth, sensations of severe cold, cutis anserina, startings, and general trembling, with small and rapid pulse, anxiety, sighing, &c. The power of the lower extremities rapidly diminishes or quite ceases, co-ordination of motion is disturbed, and sometimes the patient is unable to move the legs. Thirst, headache, insomnia, and sometimes diuresis, are added to the other symptoms. The first coldness is followed by a hot skin, frequent and full pulse, redness of the surface, injected

conjunctiva, and a profuse sweat. The paralysis of the lower extremities continues generally for a few minutes, at most for an hour; but care was taken to arrest the action of the poison by compressing the vessels above the point of insertion. The fever continues longer; sometimes, when the dose is large, for five or six days, gradually diminishing. The elimination of the poison by the kidneys appears to cease in about 24 hours. In cases of poisoning from the injection of woorari, a ligature round the limb between the place of injection and the heart, the free exhibition of diluents and evacuants, and artificial respiration when required are the measures recommended; and, as a last resource, in cases of asphyxia, tracheotomy. (*Ed. Med. Journ.*, Jan. 1867, p. 667.)

Great care was taken by M. Du Cazal in determining the proper dose of woorari, and the following are the results obtained by him; though, with the exceeding diversity in the strength of the poison, no numbers can be considered otherwise than as the mean. Fortunately, should woorari ever come into use as a medicine, the discovery of its active principle, curaria, will enable us to give entire precision to our prescriptions. According to M. Du Cazal, from 5 to 10 milligrammes (·077 to ·154 gr.) daily were borne by a dog without inconvenience; at the dose of 10 milligrammes the characteristic phenomena began to show themselves, but disappeared in a few hours; with 14 milligrammes the animal perished. For man the doses administered by subcutaneous injection were from 1 to 5 centigrammes (·1543 to ·7715 gr.), and exceptionally from 6 to 7. From these quantities, the appearance of glucose in the urine proved the presence of the poison in the system; and some slight characteristic symptoms, as dazzling, headache, vertigo, general lassitude, have appeared, but without any serious disturbance of the locomotor apparatus. M. Du Cazal also experimented with the poison therapeutically; but his trials with it were confined to chronic cases. His conclusion was that it will never become a remedy in common use. Great objections to it are its high price, and its occasional entire disappearance from the market; but were it possessed of any great therapeutic value, this difficulty could be overcome by the discovery of the locality of the plant producing it. The fact, however, as stated by M. Du Cazal, is, that it in no way modified the pathological condition in epilepsy, the only disease in which it was given, and which presents the very derangement of the nervous system, for the correction of which it would seem from its ordinary action to be peculiarly calculated. The state of the patient was in no way modified; the paroxysms recurring neither more nor less frequently than before. (*Arch. Gén.*, Sept. 1869, p. 328.) It has been prescribed in the same complaint and in chorea by M. Beigel, but without any satisfactory result. (*Ann. de Thérap.*, 1869, p. 48.) The pathological condition in which its use would seem to be especially indicated is that of acute spasmodic affections, of a very severe character, as tetanus, the poison of strychnia, and hydrophobia. Administered in tetanus, it is said by MM. Jousset and Bellesme to cause the rigidity of the muscles to cease; and this is an important result, but we are yet without evidence to prove its curative powers in that complaint. The method of exhibition is to prepare an infusion in the proportion of one part of the medicine to ten parts of boiling water, and, after filtration, to inject subcutaneously, at short intervals, a quantity of the infusion equivalent to half a centigramme (about one-thirteenth of a grain), to be increased or diminished according to its effects. (*Ann. de Thérap.*, 1866, p. 37.) Could curaria be obtained, it should be exhibited in the same way, in doses not exceeding, at first, the twentieth of that of the drug. (*Ibid.*, p. 44.) W.

WRIGHTIA ANTIDYSENTERICA. (R. Brown.) *Nerium antidysentericum.* (Linn.) An East India tree, belonging to the Apocynaceæ, the bark of which was, about a century since, in some repute in Europe as a remedy in dysentery, diarrhœa, and febrile diseases. Though no longer used in Europe, it still retains its reputation in India, among the native practitioners. Dr. Stenhouse has recently examined the seeds of this plant, and obtained from them, besides a fixed oil which they contain in large quantity, a peculiar principle called by him *wrightine*, which though uncrystallizable, and forming uncrystallizable compounds with the acids, has claims to be ranked with the alkaloids. Both wrightine and its salts have an extremely persistent bitterness. For further particulars in reference to it, the reader is referred to the *Pharmaceutical Journal* (April, 1864, p. 493). W.

XANTHORRHŒA RESINS. Two resinous substances, the products of different species of Xanthorrhœa, have been introduced into England from New Holland. They are obtained by spontaneous exudation from the stems of the plants, which are usually shrubs. One of the resins is yellow and the other red. The *yellow variety* is in tears, in flattish pieces having on one side the mark of the stem, or in masses of various size and irregular shape. It has a reddish-yellow colour, resembling gamboge when broken, and when heated emits a fragrant odour like that of Tolu balsam. It contains resin, cinnamic and benzoic acids, and a trace of volatile oil, and may therefore be ranked among the balsams. When heated with nitric acid, it yields a large product of carbazotic acid. In medical properties it is said to bear a close resemblance to storax and the balsam of Tolu. A tincture, made in the proportion of two ounces to a pint of alcohol, may be given in the dose of one or two fluidrachms. The *red variety* resembles dragon's blood in colour, and appears to be analogous to the other variety in properties. The above account has been abridged from that of Dr. Pereira in the third edition of his Materia Medica. W.

ZEA MAYS. *Indian Corn. Maize.* The common Indian corn of this country, analyzed by Mr. Archibald Polson, of Paisley, Scotland, yielded as the average result from three varieties, 12·16 per cent. of water, 1·67 of ashes, 8·83 of gluten, 54·37 of starch, 15·77 of husk and vegetable fibre, 4·50 of fat, and 2·70 of gum and sugar. (*Chem. Gaz.*, June 1, 1855, p. 211.) The late Dr. Gorham, of Boston, found 1·50 per cent. of sulphate and phosphate of lime. The meal, in the form of mush, makes an excellent emollient poultice, much used in hospitals; and a gruel may be prepared from it, which is sometimes more grateful to the sick than that made from oatmeal. A fungous product sometimes attends the growth of Indian corn, commonly known as the smut, which was submitted to examination by Mr. C. H. Cressler, and found to contain the alkaloid discovered by Winckler in ergot, and named by him secalin, now considered as a mere synonyme of propylamia. Besides the alkaloid, there were obtained a thick, viscid, fixed oil, a resin soluble in ether but not in alcohol, pectin, gluten, and a species of sugar. The morbid product may, therefore, be considered as the *ergot of maize.* (*Am. Journ. of Pharm.*, July, 1861, p. 306.) The fungus has received the title of *Ustilago maidis.* It is said to produce abortion in cows, when the diseased grain is eaten by them; and six drachms of this ergot produced the same effect on two pregnant bitches to which it was given to test its abortefacient property. (*Ibid.*, Sept. 1861, p. 413; from *Annal. Med. Vet. Belge.*) W.

ZEDOARY. *Radix Zedoariæ.* There are two kinds of zedoary, the long and the round, distinguished by the old officinal titles of *radix zedoariæ longæ*, and *radix zedoariæ rotundæ;* the former produced by the *Curcuma Zedoaria* of Roxburgh, the latter, as some suppose, by the *Kæmpferia rotunda* of Linn., but, according to others, by the *Curcuma Zerumbet* of Roxburgh. Both kinds come from the East Indies. The *long zedoary* is in slices, from an inch and a half to three inches in length, and from half an inch to an inch thick, obtuse at the extremities, and exhibiting the remains of the radical fibres. The *round* is also usually in slices, which are the sections of a roundish root, ending in a point beneath, and divided longitudinally into two parts, each of which is flat on one side, convex on the other, and heart-shaped in its outline. Sometimes the root of the latter variety is entire, and sometimes in quarters instead of halves. It is marked with circular rings on the convex surface, and, like the former, with small projecting points which are the remains of radical fibres. Both are grayish-white on the outside, yellowish-brown within, hard, compact, of an agreeable aromatic odour, and a bitterish, pungent, camphorous taste. The round, however, is less spicy than the long. They yield a volatile oil, when distilled with water. Zedoary is a warm, stimulating aromatic, useful in flatulent colic and debility of the digestive organs. It is not now employed, as it produces no effects which cannot be as well or better obtained from ginger. The dose is from ten grains to half a drachm. W.

ZERUMBET. *Cassumuniar.* Under these names an East India root was formerly used, having some analogy in sensible and medical properties to ginger, and ascribed to the *Zingiber Zerumbet* of Roscoe. Some consider the cassumuniar as a distinct root, and refer it to the *Zingiber Cassumuniar* of Roxburgh. The difference of opinion is of little importance, as neither of the roots, supposing them not to be the same, is at present to be found in the markets. By some authors the zerumbet has been erroneously confounded with the round zedoary. Geiger describes it as in pieces of the size of a fig or larger, externally grayish-brown and wrinkled, internally yellowish, hard and tough, of a biting, aromatic taste, and a spicy odour. W.

ZIZYPHUS VULGARIS. Lamarck. *Rhamnus Zizyphus.* Linn. A shrub, or small tree, growing on the shores of the Mediterranean, and cultivated in Italy, Spain, and the South of France. The fruit is the part used. This consists of oval drupes, of the size of a large olive, with a thin, coriaceous, red or reddish-brown skin, a yellowish, sweet, aciduloous pulp, and an oblong, pointed stone in the centre. These have the officinal name of *jujubæ.* By drying, their pulp becomes softer and sweeter, and acquires a vinous taste, evincing the commencement of fermentation. They are nutritive and demulcent, and are used in the form of decoction in pectoral complaints. *Jujube paste* consists, properly, of gum arabic and sugar, dissolved in a decoction of this fruit, and evaporated to the proper consistence. As a demulcent, it is in no respect superior to a paste made with gum arabic and sugar alone; and the preparation commonly sold in this country under the name, contains in fact none of the fruit.

The fruits of two other species of Zizyphus, *Z. Lotus*, growing in the North of Africa, and *Z. Jujuba*, a native of the East Indies, possess properties similar to those of the first-mentioned species, and are used as food by the inhabitants of the countries where they grow. W.

APPENDIX.

I. ART OF PRESCRIBING MEDICINES.

THE physician should be acquainted not only with the properties of medicines, and the diseases to which they are respectively applicable, but also with the art of prescribing them, so that they may be adapted to the peculiarities of individual patients, and, by the mode in which they are administered, may produce the greatest curative effect with the least possible inconvenience. In relation to these points, a few general rules will be useful for the guidance of the young practitioner, although much must be left to his own judgment and discretion. We shall compress the remarks which we have to offer, under the two heads of the quantity or dose in which medicines may be given, and the mode of their exhibition.

1. DOSE OF MEDICINES.—In the body of the work, the quantity has been stated in which each medicine must ordinarily be given to produce its peculiar effects in the adult patient. But there are various circumstances which modify the dose, and demand attention on the part of the practitioner.

The *age* of the patient is the most important of these circumstances. The young require a smaller dose than those of maturity, to produce an equal effect; and the old, though their systems are, perhaps, less susceptible to the action of medicines than those of the middle-aged, cannot bear an equally forcible impression. The following table of Gaubius, exhibiting the doses proportioned to the age, is frequently referred to.

The dose for a person of middle age being		1 or 1 drachm,
That of a person from 14 to 21 years will be		$\frac{2}{3}$ or 2 scruples,
7 to 14	" "	$\frac{1}{2}$ or $\frac{1}{2}$ a drachm,
4 to 7	" "	$\frac{1}{3}$ or 1 scruple,
of 4 years	"	$\frac{1}{4}$ or 15 grains,
3 "	"	$\frac{1}{5}$ or 10 grains,
2 "	"	$\frac{1}{8}$ or 8 grains,
1 year	"	$\frac{1}{12}$ or 5 grains.

We prefer the following simple scheme of Dr. Young, extracted from Paris's Pharmacologia.

"For children under twelve years, the doses of most medicines must be diminished in the proportion of the age to the age increased by twelve; thus, at two years to $\frac{1}{7}$; viz., $\frac{2}{2+12}=\frac{1}{7}$. At twenty-one the full dose may be given."

To the above rule some exceptions are offered in particular medicines, which require to be given to children in much larger proportional doses than those above stated. Such are castor oil and calomel, a certain quantity of which will in general not produce a greater effect in a child two or three years old than double the quantity in an adult.

Sex, temperament, and *idiosyncrasy* have also an influence upon the dose, and should be kept in view in prescribing. Females usually require somewhat smaller doses than males, and persons of sanguine temperament than the phlegmatic. Constitutional peculiarities, called idiosyncrasies, often exist in individuals, rendering them more than usually susceptible or insusceptible to the action of certain remedies, the dose of which must be modified accordingly. Thus, in some persons a grain or two of calomel will excite salivation, while in others scarcely any quantity which can be safely administered will produce this effect. Sometimes, moreover, a medicine operates on an individual in a manner wholly differ-

ent from its ordinary mode. In all such cases experience is the only sure guide; but the occasional existence of these peculiarities indicates the propriety of making particular inquiries in relation to the idiosyncrasies of those patients, for whom we may be called for the first time to prescribe.

Habit is another important circumstance which modifies the dose of medicines. Generally speaking, the susceptibility to the action of medicines is diminished by their frequent and continued use; and, in order to maintain a given impression, the quantity must be regularly increased. This is especially true in regard to the narcotics, which are sometimes borne in enormous doses by those habituated to their use. It is a good practical rule in prescribing, when circumstances demand the continuance, for a considerable length of time, of some particular effect, to vary the medicine, and employ successively several with the same general powers, so as not too rapidly to exhaust the susceptibility to the action of any individual remedy. Another important practical rule connected with the influence of habit is, when any medicine, which from its nature is of variable strength, has been employed for some time in increasing doses, to reduce the dose upon resorting to a new parcel, until its relative strength has been ascertained. A neglect of this precaution, in cases where the last parcel happened to be more powerful than that previously employed, has sometimes been followed by very serious consequences.

2. Mode of Administering Medicines.—This has reference both to the combination of medicines with one another, and the form in which they are exhibited.

Simplicity in prescription is always desirable, when no object is to be gained by deviating from it. Remedies should never be mixed together without a definite purpose, nor with the vague hope that, out of the number prescribed, some one may perchance produce a salutary impression. Those exceedingly complex prescriptions, formerly so much in vogue, of which the ingredients were so numerous as to render altogether impossible a reasonable estimate of their bearing on each other, or their effects on disease, have been generally abandoned by modern practitioners. The only ground upon which any of them can be justifiably retained is that, by very frequent trials, through a long course of years, and in various states of disease, their influence on the system may have been fully ascertained, so that they may be considered rather in the light of a single remedy than a compound of many. Upon this ground, however, no prudent physician would attempt to originate such combinations. In mixing medicines, we ought to proceed no further than we may be justified in doing by a clear knowledge of the properties and mutual relations of the several ingredients, and their fitness to answer some particular indication in the treatment of disease. There are certain principles upon which medicines may be advantageously combined, and which it may not be amiss to mention for the benefit of the young practitioner.

Remedies of the same general character may be given in connection, in order to increase their energy, or to render their action more certain. It has been well ascertained that substances thus combined will often act vigorously, when, severally, they would produce comparatively little effect; and it sometimes happens that, while their activity is augmented, they are at the same time rendered less irritating, as in the case of the drastic cathartics. (See *Pilulæ Catharticæ Compositæ.*)

Different medicines are very often mixed together, in order to meet different and coexisting indications, without any reference to the influence which they may reciprocally exert on each other. Thus in the same patient we not unfrequently meet with debility of stomach and constipation of the bowels, connected with derangement of the hepatic function. To answer the indications presented by these morbid conditions, we may properly combine, in the same dose, a tonic, cathartic, and mercurial alterative. For similar reasons we often unite tonics, purgatives, and emmenagogues, anodynes and diaphoretics, emetics and cathartics, antacids, astringents, and tonics; and scarcely two medicines can be mentioned, not absolutely incompatible with each other, which may not occasionally be combined with advantage to counteract coexisting morbid conditions.

Another very important object of combination, is the modification which is thereby effected in the actions of medicines differing from each other in properties. In this way new powers are sometimes developed, and those previously existing are greatly increased. Examples of such a result are afforded in the officinal powder of ipecacuanha and opium, and in the combination of squill and calomel; the former operating as a diaphoretic, the latter as a diuretic, beyond the capabilities of either of their constituents. The effects of one medicine are, in numerous instances, increased by the influence of another in augmenting the natural susceptibility of the system to its action. Thus, bitters enable cathartics to operate in smaller doses; purgatives awaken the dormant susceptibility to the action of mercury; and stimulants excite the torpid stomach, so that it will receive impressions from various medicines before inoperative. In some instances, the action of one medicine is promoted by that of another apparently of a nature wholly opposite. Thus, when calomel and opium are given in colic, the purgative operation of the former is facilitated by the relaxation of intestinal spasm produced by the latter. Medicines, in addition to the effects for which they are administered, very frequently produce disagreeable symptoms, which may be moderated or altogether prevented by combination with other medicines; and this object may usually be accomplished, without in the least degree interfering with the remediate influence desired. Thus, the griping produced by cathartics, and the nausea by these and various other medicines, may often be corrected by the simultaneous use of aromatics. To cover the disagreeable taste or odour of certain medicines, and to afford a convenient vehicle for their administration, are also important objects of combination; as upon these circumstances often depend the acceptability of the medicine to the stomach, and even the possibility of inducing the patient to swallow it. Substances should be preferred as vehicles which are calculated to render the medicine acceptable to the palate and stomach, and in other ways to correct its disagreeable effects; as syrups for powders, the aromatic waters for medicines given in the form of mixture, and carbonic acid water for the neutral salts.

But, in the mixing of medicines, care should be taken that they are neither chemically nor physiologically incompatible; in other words, that they are not such as will react on each other so as to produce new and unexpected combinations, nor such as will exert contrary and opposite effects upon the system. Thus, when the operation of an acid is desired, an alkali should not be given at the same time, as they unite to form a third substance entirely different from either; nor should a soluble salt of lime, baryta, or lead be given with sulphuric acid or a soluble sulphate, as decomposition would ensue, with the production of an inert compound. So, also, in relation to physiological incompatibility, diaphoretics and diuretics should not, as a general rule, be united with a view to their respective effects; as these are to a certain extent incompatible, one being diminished by whatever has a tendency to increase the other. There are cases, however, in which we may advantageously combine medicines with a view to their chemical reaction, as in the instance of the effervescing draught; and circumstances sometimes call for the union of remedies apparently opposite, as in the case of colic before alluded to, in which opium may be advantageously combined with purgatives. Still, such combinations should never be formed, unless with a full understanding of their effects, and a special reference to them.

The *form in which medicines are exhibited* is often an object of considerable importance. By variation in this respect, according to the nature of the medicine, the taste of the patient, or the condition of the stomach, we are frequently enabled to secure the favourable operation of remedies, which, without such attention, might prove useless or injurious. Medicines may be given in the solid state, as in the form of powder, pill, troche, or electuary; in the state of mixture, in which a solid is suspended in a liquid, or one liquid is mechanically mixed with another in which it is insoluble; or in the state of solution, under which may be included the various forms of infusion, decoction, tincture, wine, vinegar, syrup, honey, and oxymel. Of these different forms we

have already treated sufficiently at large, under their respective heads, in the second part of this work.

In writing extemporaneous prescriptions, neatness, order, and precision should always be observed; as, independently of the pleasing moral effect inseparable from these principles in all things, a positive practical advantage results in the greater accuracy which the habit of attending to them gives to the prescriber, and the comparative certainty which they afford that his directions will be strictly complied with. As a general rule, when medicines are combined in prescription, that should come first in order which is considered as the most prominent and important, next the adjuvant or corrigent, and lastly the vehicle. Sometimes, however, it is important to indicate to the apothecary the succession in which the substances should be combined, in reference to the perfection of the mixture; and this may render convenient a deviation from the order above mentioned. The physician should always be careful either to write out the full name of the medicine, or to employ such abbreviations as are not likely, by the misunderstanding of an ill-formed letter, to lead into error. Very serious and even fatal mistakes have been occasioned by a neglect of this precaution. The formulas of the several Pharmacopœias which are detailed in this work, will serve as good examples for the guidance of the young practitioner. The following table explains the signs and abbreviations habitually used in prescriptions. The formulas afterwards given will serve to illustrate the ordinary mode of prescribing, while they exhibit combinations of medicines frequently employed in practice. W.

Table of Signs and Abbreviations.

℞	Recipe.	Take.	Collyr.	Collyrium.	An eye-water.
āā	Ana.	Of each.	Cong.	Congius vel congii.	A gallon or gallons.
℔	Libra vel libræ.	A pound or pounds.	Decoct.	Decoctum.	A decoction.
℥	Uncia vel unciæ.	An ounce or ounces.	Ft.	Fiat.	Make.
			Garg.	Gargarysma.	A gargle.
ʒ	Drachma vel drachmæ.	A drachm or drachms.	Gr.	Granum vel grana.	A grain or grains.
℈	Scrupulus vel scrupuli.	A scruple or scruples.	Gtt.	Gutta vel guttæ.	A drop or drops.
			Haust.	Haustus.	A draught.
O	Octarius vel octarii.	A pint or pints.	Infus.	Infusum.	An infusion.
			M.	Misce.	Mix.
fʒ	Fluiduncia vel fluiduncіæ.	A fluidounce or fluidounces.	Mass.	Massa.	A mass.
			Mist.	Mistura.	A mixture.
fʒ	Fluidrachma vel fluidrachmæ.	A fluidrachm or fluidrachms.	Pil.	Pilula vel pilulæ.	A pill or pills.
♏	Minimum vel minima.	A minim or minims.	Pulv.	Pulvis vel pulveres.	A powder or powders.
Chart.	Chartula vel chartulæ.	A small paper or papers.	Q. S.	Quantum sufficit.	A sufficient quantity.
Coch.	Cochlear vel cochlearia.	A spoonful or spoonfuls.	S.	Signa.	Write.
			Ss.	Semis.	A half.

Examples of Common Extemporaneous Prescriptions.

POWDERS.

℞ Antimonii et Potassæ Tartratis gr. i.
Pulveris Ipecacuanhæ ℈i.
Fiat pulvis.
S. To be taken in a wineglassful of sweetened water.
An active emetic.

℞ Hydrargyri Chloridi Mitis,
Pulveris Jalapæ, āā, gr. x.
Misce.
S. To be taken in syrup or molasses.
An excellent cathartic in the commencement of bilious fevers, and in hepatic congestion.

℞ Pulveris Jalapæ gr. x.
Potassæ Bitartratis ʒii.
Misce.
S. To be taken in syrup or molasses.
A hydragogue cathartic, used in dropsy, and in scrofulous inflammation of the joints.

℞ Sulphuris ʒi.
Potassæ Bitartratis ʒii.
Misce.
S. To be taken in syrup or molasses.
A laxative used in piles and cutaneous diseases.

℞ Pulveris Rhei gr. x.
Magnesiæ ʒss.
Fiat pulvis.
S. To be taken in syrup or molasses.
A laxative and antacid, used in diarrhœa, dyspepsia, &c.

℞ Pulveris Scillæ gr. xii.
Potassæ Nitratis ʒi.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken twice or three times a day in syrup or molasses.
A diuretic employed in dropsy.

℞ Potassæ Nitratis ʒi.
Antimonii et Potassæ Tartratis gr. i.
Hydrargyri Chloridi Mitis gr. vi.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken every two hours in syrup or molasses.
A refrigerant, diaphoretic, and alterative, used in bilious fevers; usually called *nitrous powders*.

℞ Pulveris Guaiaci Resinæ,
Potassæ Nitratis, āā, ʒi.
Pulveris Ipecacuanhæ gr. iii.
Opii gr. ii.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken every three hours in syrup or molasses.
A stimulant diaphoretic, used in rheumatism and gout after sufficient depletion.

℞ Ferri Subcarbonatis,
Pulveris Colombæ,
Pulveris Zingiberis, āā, ʒi.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken three times a day in syrup or molasses.
A tonic, used in dyspepsia and general debility.

Pills.

℞ Pulveris Aloës,
Pulveris Rhei, āā, ʒss.
Saponis ℈i.
Misce, et cum aquâ fiat massa in pilulas viginti dividenda.
S. Two or three to be taken daily, at bedtime, or before a meal.
An excellent laxative in habitual constipation.

℞ Massæ Pilularum Hydrargyri,
Pulveris Aloës,
Pulveris Rhei, āā, ℈i.
Misce, et cum aquâ fiat massa in pilulas viginti dividenda.
S. Three to be taken at bedtime.
An alterative and laxative, useful in constipation with deranged or deficient hepatic secretion.

℞ Pulveris Aloës,
Extracti Quassiæ, āā, ʒi.
Olei Anisi ♏x.
Syrupi q. s.
Misce, et fiat massa in pilulas triginta dividenda.
S. Two to be taken once, twice, or three times a day.
A laxative, tonic, and carminative, useful in dyspepsia.

℞ Pulveris Scillæ ℈i.
Hydrargyri Chloridi Mitis gr. x.
Pulveris Acaciæ,
Syrupi, āā, q. s.
Misce, et fiat massa in pilulas decem dividenda.
S. One to be taken twice or three times a day.
A diuretic and alterative, much used in dropsy, especially when complicated with organic visceral disease.

℞ Pulveris Opii gr. iv.
Pulveris Ipecacuanhæ gr. xviii.
Pulveris Acaciæ,
Syrupi, āā, q. s.
Misce, et fiat massa in pilulas duodecim dividenda.
S. One to be taken after each stool.
An anodyne diaphoretic, useful in dysentery and diarrhœa after the use of laxatives.

℞ Pulveris Opii,
Pulveris Ipecacuanhæ, āā, gr. iii.
Hydrargyri Chloridi Mitis gr. vi.
Pulveris Acaciæ,
Syrupi, āā, q. s.
Misce, et fiat massa in pilulas tres dividenda.
S. One or more to be taken at bedtime, or according to circumstances.
An anodyne, diaphoretic, and alterative, very useful in diarrhœa, dysentery, typhoid pneumonia, and various other diseases.

℞ Plumbi Acetatis, in pulv. triti, gr. xii.
Pulveris Opii gr. i.
Pulv. Acaciæ,
Syrupi, āā, q. s. ut fiat massa in pilulas sex dividenda.
S. One every two, three, or four hours.
An astringent much employed in hæmoptysis and uterine hemorrhage.

Mixtures.

℞ Magnesiæ ʒi.
Syrupi fʒi.
Tere simul, et affunde
Aquæ Acidi Carbonici fʒiv.
Fiat haustus.
S. To be taken at a draught, the mixture being well shaken.
An agreeable mode of administering magnesia.

℞ Mannæ ʒi.
Fœniculi contusi ʒi.
Aquæ bullientis fʒiv.
Fiat infusum et cola; dein adjice
Magnesiæ Carbonatis ʒii.
Ft. mist.
S. One-third to be taken every three or four hours till it operates, the mixture being shaken.

An excellent carminative and mild laxative in flatulence and pain in the bowels.

℞ Olei Ricini fʒi.
Pulveris Acaciæ,
Sacchari, āā, ʒii.
Aquæ Menthæ Piperitæ fʒiii.
Acaciam et saccharum cum fluidunciâ dimidiâ aquæ menthæ tere; dein oleum adjice, et contere; denique aquam reliquam paulatim infunde, et omnia misce.
S. To be taken at a draught, the mixture being well shaken.

℞ Olei Ricini fʒi.
Vitellum ovi unius.
Tere simul, et adde
Syrupi fʒss.
Aquæ Menthæ Piperitæ fʒii.
Ft. haust.
S. To be taken at a draught, the mixture being well shaken.

This and the preceding formula afford convenient modes of administering castor oil, when the stomach is irritable. Any other fixed oil may be given in the same way. Half the quantity will often answer.

℞ Olei Ricini fʒiss.
Tincture Opii ℥xxx.
Pulv. Acaciæ,
Sacchari, āā, ʒii.
Aquæ Menthæ Viridis fʒiv.
Acaciam et saccharum cum paululo aquæ menthæ tere; dein oleum adjice, et iterum tere; denique aquam reliquam paulatim infunde, et omnia misce.
S. A tablespoonful to be taken every hour or two hours till it operates, the mixture being each time well shaken.

Used as a gentle laxative in dysentery and diarrhœa. It is usually known by the name of *oleaginous mixture.*

℞ Elaterii gr. i.
Spiritus Ætheris Nitrosi fʒii.
Tincturæ Scillæ,
Vini Colchici Rad., āā, fʒss.
Syrupi fʒi.
Ft. mist.
S. A tablespoonful to be taken three or four times a day in a little water.
Diuretic, used by Ferriar in dropsy.

℞ Copaibæ,
Spiritûs Lavandulæ Comp., āā, fʒii.
Mucilaginis Acaciæ fʒss.
Syrupi fʒiii.
Simul tere; dein paulatim affunde
Aquæ fʒiv.
Misce.
S. A tablespoonful to be taken four times a day, or more frequently.
Given in chronic catarrh, and chronic nephritic affections. The dose must be larger in gonorrhœa.

Neutral Mixture.

℞ Acidi Citrici ʒii.
Olei Limonis ℥i.
Simul tere, et adde
Aquæ fʒiv.
Liqua, et adde
Potassæ Carbonatis q. s. ad saturand.
Misce, et per linteum cola.

Or,

℞ Succi Limonis recentis fʒiv.
Potassæ Carbonatis q. s. ad saturandum
Misce et cola.
S. A tablespoonful to be given, with an equal quantity of water, every hour or two hours.
An excellent diaphoretic in fever.

Effervescing Draught.

℞ Potassæ Carbonatis ʒii.
Aquæ fʒiv.
Liqua.

Or,

℞ Potassæ Bicarbonatis ʒiii.
Aquæ fʒiv.
Liqua.
S. Add a tablespoonful of the solution to the same quantity of lemon or lime juice, previously mixed with a tablespoonful of water; and give the mixture in the state of effervescence, every hour or two hours.
An excellent diaphoretic and anti-emetic in fever with nausea or vomiting.

Brown Mixture.

℞ Pulv. Extract. Glycyrrhizæ,
Pulv. Acaciæ, āā, ʒii.
Aquæ ferventis fʒiv.
Liqua, et adde
Vini Antimonii fʒii.
Tincturæ Opii ℥xx.
Ft. mist.
S. A tablespoonful to be taken occasionally.
Expectorant, demulcent, and anodyne, useful in catarrhal affections.

℞ Antimonii et Potassæ Tartratis gr. i.
Syrupi Scillæ,
Liquoris Morphiæ Sulphatis, āā, fʒss.
Pulveris Acaciæ ʒii.
Syrupi fʒss.
Aquæ fʒiv.
Ft. mist.
S. A tablespoonful to be taken occasionally.
An expectorant and anodyne cough mixture.

℞ Camphoræ ʒi.
Myrrhæ ʒss.
Pulv. Acaciæ,
Sacchari, āā, ʒii.
Aquæ fʒvi.
Camphoram cum alcoholis paululo in pulverem tere; dein cum myrrhâ, acaciâ, et saccharo contere; denique cum aquâ paulatim instillatâ misce.
S. A tablespoonful to be taken for a dose, the mixture being well shaken.
A convenient form for administering camphor.

℞ Pulveris Kino ʒii.
Aquæ bullientis fʒvi.
Fiat infusum et cola; dein secundum artem admisce,
Cretæ Præparatæ ʒiii.
Tincturæ Opii fʒss.
Spiritûs Lavandulæ Compositi fʒss.
Pulveris Acaciæ,
Sacchari, āā, ʒii.
S. A tablespoonful to be taken for a dose, the mixture being well shaken.
Astringent and antacid, useful in diarrhœa.

℞ Acidi Nitrosi fʒi.
Tincturæ Opii gtt. xl.
Aquæ Camphoræ fʒviii.
Misce.
S. One-fourth to be taken every three or four hours.
Hope's mixture, used in dysentery, diarrhœa, and cholera.

℞ Cretæ Præparatæ ℈iv.
Massæ Pil. Hydrarg. gr. viii.
Tincturæ Opii gtt. viii.
Pulveris Acaciæ,
Sacchari, āā, ʒi.
Aquæ Cinnamomi,
Aquæ, āā, fʒi.
Solida simul tere, dein liquida paulatim inter terendum adjice, et omnia misce.
S. A teaspoonful to be taken for a dose, the mixture being well shaken.
An antacid and alterative mixture, well adapted to infantile diarrhœa, with white stools. The dose mentioned is for a child a year or two old, and may be repeated four or six times in twenty-four hours.

Solutions.

℞ Magnesiæ Sulphatis ʒi.
Syrupi Limonis fʒi.
Aquæ Acidi Carbonici fʒvi.
Misce.
S. To be taken at a draught.
An agreeable mode of administering sulphate of magnesia.

℞ Quiniæ Sulphatis gr. xii.
Acidi Sulphurici Aromatici gtt. xxiv.
Syrupi fʒss.
Aquæ Menthæ Piperitæ fʒi.
Misce.
S. A teaspoonful to be taken every hour or two hours.
A good mode of administering sulphate of quinia in solution.

℞ Magnesiæ Sulphatis ʒi.
Antimonii et Potassæ Tartratis gr. i.
Succi Limonis recentis fʒi.
Aquæ fʒiii.
Misce.
S. A tablespoonful to be taken every two hours till it operates upon the bowels.
Useful in fevers.

℞ Potassæ Nitratis ʒi.
Antimonii et Potassæ Tartratis gr. i.
Aquæ fʒiv.
Liqua.
S. A tablespoonful to be taken every two hours.
A refrigerant diaphoretic, used in fevers.

Infusions.

℞ Sennæ ʒiii.
Magnesiæ Sulphatis,
Mannæ, āā, ʒss.
Fœniculi ʒi.
Aquæ bullientis Oss.
Macera per horam in vase leviter clauso, et cola.
S. A teacupful to be taken every four or five hours till it operates.
An excellent purgative in febrile complaints.

℞ Colombæ contusæ,
Zingiberis contusi, āā, ʒss.
Sennæ ʒii.
Aquæ bullientis Oi.
Macera per horam in vase leviter clauso, et cola.
S. A wineglassful to be taken morning, noon, and evening, or less frequently if it operate too much.
An excellent remedy in dyspepsia with constipation and flatulence.

℞ Spigeliæ ʒss.
Sennæ ʒii.
Mannæ ʒi.
Fœniculi ʒii.
Aquæ bullientis Oi.
Macera per horam in vase leviter clauso, et cola.
S. A wineglassful to be given to a child from two to four years old, three or four times a day.
A powerful anthelmintic.

℞ Pulveris Cinchonæ Rubræ ʒi.
Acidi Sulphurici Aromatici fʒi.
Aquæ Oi.
Macera per horas duodecim, subinde agitans.
S. A wineglassful of the clear liquid to be taken for a dose.
A good method of administering Peruvian bark in cold infusion.

II. TABLES OF WEIGHTS AND MEASURES.

APOTHECARIES' WEIGHT. *U. S.*

Pound.		Troyounces.		Drachms.		Scruples.		Troy Grains.
℔ 1	=	12	=	96	=	288	=	5760
		℥ 1	=	8	=	24	=	480
				℥ 1	=	3	=	60
						℈ 1	=	gr. 20

The Imperial Standard Troy weight, at present recognised by the British laws, corresponds with the Apothecaries' weight in pounds, ounces, and grains, but differs from it in the division of the ounce, which, according to the former scale, contains twenty pennyweights, each weighing twenty-four grains.

AVOIRDUPOIS WEIGHT. *Br.*

In converting the weights of liquids heavier or lighter than water into measures, or conversely, a correction must be made for specific gravity. In converting weights into measures, the calculator may proceed as if the liquid was water, and the obtained measure will be to the true measure *inversely* as the specific gravity. In the converse operation, of turning measures into weights, the same assumption may be made, and the obtained weight will be to the true weight *directly* as the specific gravity.

FRENCH DECIMAL WEIGHTS AND MEASURES.

The French *metrical* system is based upon the idea of employing, as the unit of all measures, whether of length, capacity, or weight, a uniform unchangeable standard, adopted from nature, the multiples and subdivisions of which should follow in decimal progression. To obtain such a standard, the length of one-fourth part of the terrestrial meridian, extending from the equator to the pole, was ascertained. The ten-millionth part of this arc was chosen as the unit of measures of length, and was denominated *metre*. The cube of the tenth part of the metre was taken as the unit of measures of capacity, and denominated *litre*. The weight of distilled water, at its greatest density, which this cube is capable of containing, was called *kilogramme*, of which the thousandth part was adopted as the unit of weight, under the name of *gramme*. The multiples of these measures, proceeding in the decimal progression, are distinguished by employing the prefixes, *deca*, *hecto*, *kilo*, and *myria*, taken from the Greek numerals; and the subdivisions, following the same order, by *deci*, *centi*, *milli*, from the Latin numerals.

The *metre*, or unity of length, at 32°,	= 39·371	English inches at 62°.
The *litre*, or unity of capacity,	= 61·028	English cubic inches.
The *gramme*, or unity of weight,	= 15·434	Troy grains.

Upon this basis the following tables, taken with some slight alterations from the Edinburgh New Dispensatory, have been constructed. It was ascertained by accurate examination at the London Mint, that the gramme is only 15·434 Troy grains, though sometimes stated at 15·444 grains.

MEASURES OF LENGTH.

The metre being at 32°, and the foot at 62°.

Though the decimal system of weights and measures was established by law in France, it was found impossible to procure its general adoption by the people, who obstinately adhered to the old *poids de marc* and its divisions; or, if they adopted the new weights, gave them the names of the old weights to which they most nearly approached. Thus, the *kilogramme*, which is equal to 18,827$\frac{15}{100}$ French grains, or 2 pounds 5 gros 35$\frac{15}{100}$ grains *poids de marc*, was divided into two parts, and the half of it called a pound. One reason for this adherence to the old weights was the convenience of division into halves, quarters, &c., of which the new were not susceptible. To obviate this difficulty the Imperial government legalized the employment of the half kilogramme as the unit of weight, under the name of pound, and allowed this to be divided into half pounds, quarters, eighths, ounces, &c., as in the old *poids de marc*. The new pound is distinguished by the name of *metrical pound*, and has been adopted to a considerable extent; while the old weights are retained by some, particularly by the apothecaries and goldsmiths; so that three systems are now more or less in use in France—the original *poids de marc*, the decimal system, and the metrical pound with its divisions. The following table represents the relative value of these different weights.

Decimal System.		Poids de Marc.					Metrical Pound.

			1 fluidrachm	=	0·003599 "
			1 minim	=	0·000059 "

The following table is taken from Christison's Dispensatory, and was calculated chiefly from data contained in Soubeiran's Traité de Pharmacie.

Table of certain foreign Apothecaries' Weights, exhibiting the Value of their different Denominations in Troy Grains.

	Pound.	Ounce.	Drachm.	Scruple.	Grain.
French (old)	5670·5	472·50	59·10	19·70	0·820
Spanish	5320·4	443·49	55·44	18·47	0·769
Tuscan	5240·3	436·67	54·58	18·19	0·758
Roman	5235·0	436·25	54·53	18·17	0·757
Austrian	6495·1	541·25	67·65	22·55	1·127
German or Nuremberg Russian	5524·8	460·40	57·55	19·18	0·960
Prussian	5415·1	451·26	56·40	18·80	0·940
Dutch Belgian	5695·8	474·64	59·33	19·78	0·988
Swedish	5500·2	458·34	57·29	19·09	0·954
Piedmontese	4744·7	395·39	49·45	16·48	0·824
Venetian	4661·4	388·45	48·55	16·18	0·809

Of these weights, all except the French, Spanish, Tuscan, and Roman (first named in the table), are divided into parts corresponding with those of the English Apothecaries' weight. In these four, the drachm contains 72 instead of 60 grains, and the scruple 24 instead of 20 grains; but, as in the English, there are 3 scruples in the drachm, 8 drachms in the ounce, and 12 ounces in the pound.

APPROXIMATE MEASUREMENT.

For the sake of convenience, in the absence of proper instruments, we often make use of means of measurement, which, though not precise nor uniform, afford results sufficiently accurate for ordinary purposes. Of this kind are certain household implements, of a capacity approaching to uniformity, and corresponding to a certain extent with the regular standard measures. Custom has attached a fixed value to these implements, with which it is proper that the practitioner should be familiar; although their capacity, as they are now made, with the exception of the wineglass, generally somewhat exceeds that at which they were originally and still continue to be estimated.

A *tea-cup* is estimated to contain about four fluidounces, or a gill.
A *wineglass* - - - - - - two fluidounces.
A *tablespoon* (cochlear magnum) - half a fluidounce.
A *teaspoon* (cochlear parvum) - - a fluidrachm.

In reading French medical works, if unacquainted with their customary expressions of measure, we are often left in great uncertainty as to the precise quantity indicated by the names. The following table, translated from the French Codex of 1866, will obviate this difficulty.

	Grammes.
A coffeespoon (*cuillerée à café*, Fr., *teaspoon*) - - - -	5
A common spoon (*cuillerée*, Fr., *tablespoon*), 4 coffeespoons, or -	20
A glass (*verre*, Fr.), 8 common spoons - - - - - -	160
A handful (*poignée*, Fr.) of barleyseed - - - - - -	80
" " " flaxseed - - - - - -	50
" " " flaxseed-meal - - - - -	150
" " " dried mallow leaves - - - -	40
" " " " chicory, " - - - -	30
A pinch (*pincée*, Fr.) of chamomile flowers - - - - -	2
" " " arnica " - - - - -	1
" " " marshmallow " - - - - -	2
" " " mallows " - - - - -	1
" " " linden " - - - - -	2
" " " fruits of anise - - - - -	2
" " " " fennel - - - - -	2
A hen's egg, newly weighed, has the mean weight of - - -	64
" the white alone - - - - - - -	40
" the yellow alone - - - - - - -	20
Blanched almonds have the mean weight, each, of - - -	1

Small quantities of liquid medicines are often estimated by *drops*, each of which is usually considered equivalent to a minim, or the sixtieth part of a fluidrachm. The drop of water and of watery fluids is, on an average, about that size; but the same is by no means the case with all medicinal liquids, and the drop even of the same liquid varies much in bulk, according to the circumstances under which it is formed. This is, therefore, an uncertain mode of estimating the quantity of liquids, and should be superseded where minim measures can be had. Certain general rules, however, influence the formation of drops, which will enable us to form some notion of their probable relative number, in the same amount of liquid, when possessed of the requisite data. Thus, the heavier the liquid the smaller, other things being equal, is the size of the drops, and the greater their number in a given measure. The drop of chloroform, for example, which is a very heavy liquid, is very small, much smaller than that of alcohol or ether. The greater or less viscidity, and greater or less mobility of the liquid have much influence, the former in increasing, the latter in diminishing the size of the drops. The adhesiveness of liquids, which opposes their disposition to leave the surface from which they fall, re-

quires a greater mass to overcome it, and consequently augments the size of the drop. The rapidity of the movement acts in a contrary direction, and the drop from a full bottle should be less than from one more or less emptied. The broader the surface from which they fall, the greater is their size. The drops from a thick-lipped bottle are larger than from one with thin lips.

The results stated in the following table were obtained by Mr. E. Durand, of Philadelphia. (See *Journ. of the Philadelphia College of Pharmacy*, i. 169.) They may be relied on as accurate, but should be considered as indicating only the relative number of drops afforded by the several liquids mentioned; for, under other circumstances than those of Mr. Durand's experiments, entirely different results might be obtained as relates to each liquid. The preparations experimented with were those of the first edition of the U. S. Pharmacopœia.

Table, exhibiting the Number of Drops of different Liquids equivalent to a Fluidrachm.

	Drops.		Drops.
Acid, acetic (crystallizable)	120	Tincture of assafetida, of foxglove, of guaiac, of opium	120
Acid, hydrocyanic (medicinal)	45	Tincture of chloride of iron	132
Acid, muriatic	54	Vinegar, distilled	78
Acid, nitric	84	Vinegar of colchicum	78
Acid, nitric, diluted (1 to 7)	51	Vinegar of opium (black drop)	78
Acid, sulphuric	90	Vinegar of squill	78
Acid, sulphuric, aromatic	120	Water, distilled	45
Acid, sulphuric, diluted (1 to 7)	51	Water of ammonia (strong)	54
Alcohol (rectified spirit)	138	Water of ammonia (weak)	45
Alcohol, diluted (proof spirit)	120	Wine (Teneriffe)	78
Arsenite of potassa, solution of	57	Wine, antimonial	72
Ether, sulphuric	150	Wine of colchicum	75
Oil of aniseed, of cinnamon, of cloves, of peppermint, of sweet almonds, of olives	120*	Wine of opium	78

* See *page* 1303 for the results obtained by Professor Procter with the volatile oils, which give a considerably smaller number of drops to the fluidrachm than here stated showing how different may be the results under different circumstances.

* This table includes all the elements, although several of them are not used in medicine It also embraces a few compounds which are not used in pharmacy, but which are inserted on account of their general importance. Excluding aridium and donarium, which have not maintained their claim to be considered as distinct metals, the present number of the elements is 66; three new metals having been discovered since the eleventh edition of the Dispensatory was published.

† By modern chemists the elements are designated by letters, called *symbols*. The initial letter of the name is the symbol, whenever it is distinctive; but, when several elements have names beginning with the same letter, the plan adopted is to represent one of them by the initial letter, and the rest by the initial letter with some other associated with it. Thus C stands for carbon, Ca for calcium, Cd for cadmium, Ce for cerium, Cl for chlorine, Co for cobalt, Cr for chromium, Cu for copper, &c. The use of these symbols saves time and space in designating the composition of compounds. Where a single equivalent is intended to be designated, the symbol of the element is simply given; but where several equivalents are to be represented, the symbol is preceded by a figure indicating the number. Thus C means one equivalent of carbon, 2C two equivalents, and so on. The number of equivalents is now generally denoted by a small depressed figure following the symbol; and this plan has been adopted in the above table. The group of letters and figures, thus used to denote the composition of any compound, is called the *formula* of such compound. The symbols given are those of Berzelius, and should not be varied from, for fear of destroying their usefulness by creating confusion.

* Niobium and pelopium were alleged to exist in the Bavarian and North American columbites. Recently, however, M. H. Rose has announced that they are the same, and proposes to retain the name niobium. It is not contended that the peculiar metal of the columbites is different from that discovered in 1801 by Hatchett; and, therefore, as justly remarked by Prof. A. Connell, of St. Andrews, it should be called columbium, the name given to it by its discoverer, and the name niobium should be abandoned. (*Philos. Mag.* June, 1854, p. 461.)

B.

* Several of the numbers in this table have been slightly altered to correspond with those most recently admitted; and a few have been given originally, either with new substances introduced into the table, as carbolic and cinnamic acids, or for bodies of which the eq. has been but recently satisfactorily ascertained, as erbium and niobium.

IV. TABLES

SHOWING THE SPECIFIC GRAVITY CORRESPONDING WITH THE SEVERAL DEGREES OF HYDROMETERS IN USE.

Baumé's hydrometer is usually employed. In this instrument, the sp. gr. of distilled water is assumed as the zero of the descending scale, in relation to fluids heavier than itself, and as 10 on the ascending scale in relation to lighter fluids. In the following tables, the specific gravity of liquids is given, corresponding with the several degrees of this hydrometer. The first column of specific gravities is taken from the French Codex, and is, therefore, of high authority. The second is the one given in previous editions of this work, taken from Duncan's Edinburgh Dispensatory (A. D. 1830), and based on the calculations of Huss. The third column was calculated by Mr. Henry Pemberton, of Philadelphia, in 1851, and is recognised by the Philadelphia College of Pharmacy. The figures in this column correspond with the degrees of the hydrometers prepared by Dr. W. H. Pile, of this city, which may be relied on for their accuracy.

For Liquids lighter than Water.

The following formulas, furnished by Dr. Pile, may prove useful by enabling any one to calculate the sp. gr. corresponding with the several degrees of Baumé's hydrometer, and, conversely, the degree of Baumé corresponding with the sp. gr.

1. *For Liquids lighter than Water.* The following formulas give the sp gr. as represented in the first column in the foregoing table; or, the specific gravity being known, gives the corresponding degree of Baumé.

$$\frac{144}{B^\circ+134} = \text{sp. gr.}; \text{ and } \frac{144}{\text{sp. gr.}} - 134 = B^\circ.$$

The following formulas apply to the third column of specific gravities.

$$\frac{140}{B^\circ+130} = \text{sp. gr.}; \text{ and } \frac{140}{\text{sp. gr.}} - 130 = B^\circ.$$

2. *For Liquids heavier than Water.* For the first column, $\frac{144}{144-B^\circ} = \text{sp. gr.}$, and $144 - \frac{144}{\text{sp. gr.}} = B^\circ$; for the third, $\frac{145}{145-B^\circ} = \text{sp. gr.}$, and $145 - \frac{145}{\text{sp. gr.}} = B^\circ$.

Gay-Lussac's centesimal alcoholmeter is applicable only to alcohol. The scale of this instrument is divided into 100 unequal degrees, the zero corresponding to pure water, and 100° to absolute alcohol; and every intermediate degree expresses the percentage of pure alcohol, by measure, contained in the liquors examined. Thus, when the instrument stands at 40° in any alcoholic liquid, it indicates that 100 measures of the liquid contain 40 of pure alcohol and 60 of water. But, as it was graduated for the temperature of 59° of Fahrenheit, the liquors to be tested should be brought to that temperature. *Tralles' centesimal alcoholmeter* is the one used by the U. S. Government in gauging the strength of spirit; and is generally employed in this country by distillers and wholesale dealers in the purchase and sale of alcoholic liquors. The scale of this instrument is like Gay-Lussac's divided into 100 unequal parts, each corresponding to the percentage by volume of pure alcohol contained in the liquors examined. As the sp. gr. of water is considered as unity at its temperature of greatest density 39·8° F., and the degrees of this scale are calculated for 60° F., the zero, corresponding to the density of water, will represent a sp. gr. of ·9991.

The following table of Tralles gives the percentage of alcohol *by measure* corresponding with the specific gravity. Under alcohol in the first part of this work (*page* 80) a table of the percentage by weight corresponding with the sp. gr. is given. By means of these tables, in connection with the alcoholmeter, every problem that can arise in reference to the strength of spirituous liquors can be solved; and by the appended table, giving the value of Baumé's degrees in those of Tralles, the facility is still further extended.

Alcoholmetrical Table of Tralles.

Alcohol in 100 measures of spirit.	Specific gravity at 60° Fahr.	Alcohol in 100 measures of spirit.	Specific gravity at 60° Fahr.	Alcohol in 100 measures of spirit.	Specific gravity at 60° Fahr.	Alcohol in 100 measures of spirit.	Specific gravity at 60° Fahr.

V. CORRESPONDENCE BETWEEN DIFFERENT THERMOMETERS.

In *Fahrenheit's* thermometer, which is universally employed in this country and Great Britain, the freezing point of water is placed at 32°, and the boiling point at 212°, and the number of intervening degrees is 180.

The *centigrade* thermometer, which has long been used in Sweden under the name of Celsius's thermometer, and is now most generally employed on the continent of Europe, marks the freezing point *zero*, and the boiling point 100°.

In *Reaumur's* thermometer, used in France before the revolution, the freezing point is at *zero*, and the boiling point at 80°.

In *De Lisle's* thermometer, used in Russia, the graduation begins at the boiling point, which is marked *zero*, while the freezing point is placed at 150°.

From the above statement, it is evident that 180 degrees of Fahrenheit are equal to 100° of the centigrade, 80° of Reaumur, and 150° of De Lisle; or 1 degree of the first is equal to $\frac{5}{9}$ of a degree of the second, $\frac{4}{9}$ of a degree of the third, and $\frac{5}{6}$ of a degree of the last. It is easy, therefore, to convert the degrees of one into the equivalent number of degrees of the other; but, in ascertaining the corresponding points upon the different scales, it is necessary to take into consideration their different modes of graduation. Thus, as the zero of Fahrenheit is 32° below the point at which that of the centigrade and of Reaumur is placed, this number must be taken into account in the calculation. The following propositions will embrace all the cases which can arise in relation to the three last-mentioned thermometers. That of De Lisle is seldom or never referred to in works which are read in this country.

1. If any degree on the *centigrade* scale, either above or below zero, be multiplied by 9 and divided by 5, or if any degree of *Reaumur* above or below zero be multiplied by 9 and divided by 4, the quotient will, in either case, be the number of degrees above or below 32°, or the freezing point of *Fahrenheit.*

2. The number of degrees between any point of *Fahrenheit's* scale and 32°, if multiplied by 5 and divided by 9, will give the corresponding point on the *centigrade;* if multiplied by 4 and divided by 9, will give the corresponding point on the scale of *Reaumur.*

3. Any degree of the *centigrade* multiplied by 4 and divided by 5, will give the corresponding degree of *Reaumur;* and, conversely, any degree of *Reaumur* multiplied by 5 and divided by 4, will give the corresponding degree of the *centigrade.*

Potassa, hydriodate of 1354
Potassa, hypermanganate of 708
Potassa, impure carbonate of 698
Potassa, iodate of 1619
Potassa, nitrate of 703
Potassa, permanganate of 708
Potassa, phosphate of 1676
Potassa, preparations of 1334
Potassa, prussiate of 714
Potassa, pure carbonate of 1340
Potassa, quadroxalate of 1666
Potassa, red prussiate of 1595
Potassa, sesquicarbonate of 1343
Potassa, silicate of 1695
Potassa, solution of 1263
Potassa, sulphate of 712
Potassa sulphurata 1359
Potassa, supertartrate of 696
Potassa, tartrate of 1346
Potassa with lime 1336
Potassa, yellow prussiate of 714
Potassæ acetas 1337
Potassæ biantimonias 1588
Potassæ bicarbonas 1341
Potassæ bichromas 695
Potassæ bisulphas 1547
Potassæ bitartras 696
Potassæ carbonas 1338
Potassæ carbonas impura 698
Potassæ carbonas pura 1340
Potassæ chloras 701
Potassæ citras 1344
Potassæ et sodæ tartras 1345
Potassæ nitras 703
Potassæ permanganas 708
Potassæ phosphas 1676
Potassæ, prussias flava 714
Potassæ sulphas 712
Potassæ sulphas cum sulphure (note) 713
Potassæ tartras 1346
Potassæ tartras acida 696
Potassii bromidum 1348
Potassii cyanidum 1350
Potassii cyanuretum 1350
Potassii ferrocyanidum 714
Potassii iodidum 1353
Potassii sulphocyanidum 1705
Potassii sulphuretum 1359
Potassio-ferric alum 1173
Potassio-tartrate of iron 1174
Potassium 694
Potassium, bromide of 1348
Potassium, cyanide of 1350
Potassium, cyanuret of 1350
Potasssium, ferridcyanide of 1595
Potassium, ferrocyanide of 714
Potassium, ferrocyanuret of 714
Potassium, iodide of 1353
Potassium, iodohydrargyrate of 1624
Potassium, sulphocyanide of 1705
Potassium, sulphuret of 1359
Potassium, teroxide of 694
Potato 868
Potato flies 214
Potato spirit oil 85
Potato starch 121, 551
Potentilla reptans 1680
Potentilla tormentilla 868
Pothos 867
Potus imperialis 698
Poultices 1075

Sapo durus 773
Sapo guaiacinus 443
Sapo mollis 774, 777
Sapo vulgaris 775, 777
Sapogenin 796
Saponaria officinalis 1690
Saponification 774
Saponin 1690
Sapota Mulleri (note) 443
Sappan wood 1549
Saratoga water 141
Sarcocolla 1690
Sarcocollin 1691
Sarcolactic acid 1667
Sarracenia 1691
Sarracenia flava 1691
Sarracenia purpurea 1691
Sarracenia variolaris 1691
Sarsæ radix 778
Sarsaparilla 778
Sarsaparilla beer (note) 783
Sarsaparilla, false 143
Sarsaparilla, Indian 451
Sarsaparillin 781
Sassa 1691
Sassa gum 1691
Sassafras medulla 783
Sassafras officinale 783
Sassafras pith 783, 784
Sassafras radicis cortex 783
Sassafras radix 783
Sassafras root, bark of 783, 784
Sassafrid 784
Sassy bark 1692
Saturation 941
Satureja hortensis 1692
Satureja montana 1692
Saunders 1689
Saunders, red 772, 1689
Saunders, white 1690
Saunders, yellow 1690
Saururus cernuus 1692
Savanilla rhatany (note) 515
Savine 752
Savine cerate 1082
Savine, fluid extract of (note) 753
Savine tops 752
Savory 1692
Saxifraga 1678
Scabiosa arvensis 882
Scabiosa succisa 882
Scabious 385, 882
Scales of iron 1185
Scammoniæ radix 785
Scammoniæ resina 1388
Scammonii resina 1388
Scammonium 785
Scammony 785
Scammony, Aleppo 786
Scammony, factitious 789
Scammony in shells 787
Scammony, lachryma (note) 786, 788
Scammony mixture 1286
Scammony, Montpellier 789
Scammony, resin of 1388
Scammony root 785
Scammony, Smyrna 786, 788
Scammony, virgin 787
Scammony, virgin (note) 788
Scandix cerefolium 1536
Scarlet pimpernel 1532
Schuylkill muscadel grape 891
Schuylkill water 138
Scilla 790
Scilla maritima 790
Scillitin 790, 791
Sclerotium clavus (note) 378
Scolopendrium officinarum 1692
Scoparii cacumina 792
Scoparin 793
Scoparius 792
Scotch fir 862
Scouring rush 1590
Scrophularia nodosa 1693
Scrophularin 1693
Scrophularosmin 1693
Scullcap 793
Scullcap, European 793
Scuppernong grape 892
Scurvy-grass 1574

Xanthorrhœa hastilis 1604
Xanthorrhœa resins 1724
Xanthoxylene (note) 900
Xanthoxylin 901
Xanthoxylin (note) 900
Xanthoxylum 900
Xanthoxylum alatum (note) 900
Xanthoxylum Americanum 90'
Xanthoxylum Carolinianum 901
Xanthoxylum clava Herculis 901
Xanthoxylum fraxineum 901
Xylic alcohol 87
Xylobalsamum 1541
Xyloidin 120

Y

Yam 550
Yarrow 17
Yeast 399
Yeast, dried (note) 400
Yeast poultice 1075
Yelk 657
Yellow amorphous oxide of mercury (note) 1215
Yellow bark 270, 280
Yellow bark of Guayaquil (note) 285
Yellow Carthagena bark, common 289
Yellow cinchona 262
Yellow cinchona bark 262
Yellow dock 748
Yellow gentian 422
Yellow jasmine 421
Yellow ladies' bedstraw 1600
Yellow ladies' slipper 359
Yellow mercurial lotion 1277
Yellow parilla 1640
Yellow pine 861
Yellow prussiate of potash 714
Yellow puccoon 469
Yellow resin 726
Yellow saunders 1690
Yellow soap, common 776
Yellow sulphate of mercury 1217
Yellow wash 1201, 1276
Yellow wax 245
Yellow-dye tree of Soudan 1575
Yellow-flowered rhododendron 1687
Yellow-root 469, 90C
Yew tree, common European 1707
Young fustic 1599

Z

Zamia arrow-root 551
Zamia integrifolia 550
Zamia lanuginosa 768
Zea mays 1725
Zedoary 1725
Zerumbet 1725
Zibethum 1569
Zinc 902
Zinc, acetate of 1507
Zinc, butter of 1509
Zinc, carbonate of 1508, 1552
Zinc, chloride of 1509
Zinc colic 903
Zinc, cyanide of 1586
Zinc, cyanuret of 1586
Zinc, ferrocyanide of 1595
Zinc, ferrocyanuret of 1595
Zinc, flowers of 1513
Zinc, granulated 1515
Zinc, impure oxide of 1716
Zinc, iodide of 1623
Zinc, lactate of 1628
Zinc, oxide of 1512
Zinc, phosphate of 1677
Zinc, precipitated carbonate of 1508
Zinc, preparations of 1507
Zinc, silicate of 1552
Zinc, solution of chloride of 1274
Zinc, sulphate of 903
Zinc, table of the preparations of 903
Zinc, valerianate of 1514
Zinci acetas 1507
Zinci carbonas 1508
Zinci carbonas præcipitata 1508
Zinci chloridi liquor 1274
Zinci chloridum 1509
Zinci cyanidum 1586
Zinci ferrocyanidum 1595
Zinci iodidum 1623
Zinci lactas 1628
Zinci oxidum 1512
Zinci phosphas 1677
Zinci sulphas 903
Zinci valerianas 1514
Zincum 902
Zincum granulatum 1515
Zingiber 906
Zingiber cassumniar 1725
Zingiber officinale 906
Zingiber zerumbet 1725
Zittmann's decoction (note) 1101
Zizyphus jujuba 1725
Zizyphus lotus 1725
Zizyphus vulgaris 1725
